PHARMACEUTICAL MEETING.

Wednesday Evening, October 4th.

The Inaugural Meeting of the Session 1871-2 was held on Wednesday evening, October 4. There was a large number of ladies and gentlemen present to witness the distribution of prizes to the successful students of the past session, and to hear Mr. John Mackay's address to those about to commence or resume their labours.

The chair was occupied by A. F. HASELDEN, Esq., F.L.S., President of the Society.

The following donations to the Museum were announced, and the thanks of the meeting were given to the respective donors:—

Specimens of Condurango: presented by Drs. Farre and Redwood,—Chloral Hydrate: by Mr. Barrett,—Chloral Hydrate, Fuming and Purified: by Dr. Versmann,—Poison Bottles; Bottle Guards: by Messrs. Frazer and Green,—Aloin: presented by Messrs. T. and H. Smith,—Oxalate of a New Cinchona Alkaloid: presented by Mr. D. Howard,—Specimens of Unclayed Manilla Sugar and Pure Crystals of Cane Sugar prepared from the same: presented by Mr. W. W. Stoddart,—Specimens of Sulphate of Strontia (Celestine) and Crystallized Peroxide of Iron (Hæmatite); presented by Mr. W. W. Stoddart,—Iodides of Ammonium and Potassium: presented by Messrs. Southall, Son and Dymond,—Bark and Leaves of *Alstonia constricta*, F. Mueller: presented by Dr. J. Bancroft, Brisbane Hospital,—Bundle of Connoch Chumpa Flowers from Calcutta: presented by Mr. H. W. Pound,—Seeds of Cinchona: presented by Mr. D. Hanbury, F.R.S.,—A Collection of 306 specimens of Chinese Materia as described in Dr. Porter Smith's work: presented by Mr. D. Hanbury, —Specimens of the following Indian Drugs:—Seeds of *Carthamus tinctorius;* Bombay Liquorice Root; seeds of *Plantago Ispaghula;* seeds of *Nelumbium speciosum*; White Mustard Seeds; Mysore Poppy Capsules; Resin of *Vateria Indica;* Resin of *Shorea robusta;* Candeish Opium; Arrowroot of *Curcuma angustifolia;* Stems of *Nardostachys Jatamansi;* Roots of *Hedychium spicatum;* Hooghly Safflower; Black Dammar from Coorg; Bark of *Samadera Indica;* Fruits of *Datura alba:* presented by Dr. Forbes Watson,—Dried Specimen of *Andromeda Leschenaultii;* Methyl-salicylic Oil obtained from the leaves of *Andromeda Leschenaultii;* Salicylic Acid, an intermediate product obtained in the preparation of Carbolic Acid from the same plant: Phenol, or Carbolic Acid, prepared also from the above plant—prepared by J. Broughton, Esq.: presented by Dr. Forbes Watson,—A New Powder Folder: presented by Messrs. Maw, Son and Thompson,—A New Poison Bottle Guard: presented by Messrs. Maw, Son and Thompson.

The PRESIDENT said,—The programme before us this evening is one entirely of a pleasurable character; I am truly thankful that there will be no political feature about it. In the first place our professors will give their usual, and, as I anticipate, satisfactory report of the pupils during the past session; the prizes will then be distributed and a few words of congratulation addressed to the candidates, after which our good friend and colleague, Mr. Mackay, will deliver the inaugural address. Permit me in the meantime to offer a hearty welcome to you who by your presence to-night upon the commencement of this session, show that you take an interest, not only in the distribution of our prizes, but, as I believe, in all that pertains to the prosperity of our Society. Since we made bold, and we were rather shy at first, to ask the ladies to attend upon these occasions, my predecessors have said a separate word of welcome in their favour, and I see no reason why I should deviate from so excellent a custom. They render every cheerful scene more cheerful and every pleasure greater, their presence acting as it were like a sunbeam. With the poet's words I sincerely welcome them,—

> "All honour to woman, to her it is given
> To wreathe the dull earth with the roses of heaven."

The PRESIDENT then called upon Professor Redwood to present his report with regard to the class of chemistry and pharmacy.

Professor REDWOOD said the task, or perhaps he should rather say the duty, that the professors had to perform at the opening meeting of every session of their school, was always a pleasant one, and especially so when they had a good list of prizes to be distributed to a number of good men who had acquitted themselves with credit in a previous session. Far more agreeable was the duty which they had to perform at the opening than that which devolved upon them at the closing of a session, when they had to finish the work of a long ten months' application to study by inviting the students to a contest—a friendly contest it might be, but one nevertheless in which there were many anxious thoughts, and some misgivings with reference to the result. The hopes and sometimes the confident expectations of some of those who entered the lists were necessarily doomed to disappointment, and many a hard-working, well-conducted, and meritorious student found himself unfortunately in the position of an unsuccessful candidate, and had to return to his friends without the coveted distinction of being a prize-man. They could not award prizes to all, and must necessarily cause disappointment to many, some of whom might go away, as no doubt they often did at the conclusion of a session, discontented with themselves and dissatisfied with the result of their sessional labours in the school. That was the scene at the closing of a session. Now at the opening of a session it was otherwise. He need not tell them what it was, for it was before them; they had forgotten the bad and all disagreeables, and thought only of the good. They had a good number of prizes which had been awarded to a considerable number of able men who had amply justified their claims for these distinctions, and they had invited the members, and the ladies especially, to confer a smile of approbation upon those who would come forward that evening to receive these distinctions. In his class there were at the close of last session eleven candidates for prizes, to six of whom some marks of distinction had been awarded, and they were as follows:—

Silver Council Medal	Henry Churchill.
Bronze Council Medal	Charles Arthur Overton.
Certificates of Honour	Horace Davenport. Thomas Iredale.
Certificates of Merit	Frederick J. Hanbury. Walter Benjamin Cole.

In conclusion, he (the Professor) could state most truly that the whole of these gentlemen had richly merited the distinctions which had thus been conferred upon them.

The questions for examinations were as follows:—

CHEMISTRY AND PHARMACY.

Hours: Ten till One. Standard Number of Marks, 100.

1. What is the weight of a fluid ounce of rectified spirit?
2. What is the specific gravity of a liquid, a fluid ounce of which weighs 321·5625 grains?
3. How do you explain the difference between common light and polarized light?
4. When a ray of polarized light passes through a tube filled with oil of turpentine, what effect is produced on the ray, and how do you explain it in accordance with the undulatory theory of light?
5. Describe and explain the phenomena of fluorescence, and give a few instances illustrating their occurrence in liquids and solids.
6. Explain the terms specific heat and latent heat; describe the methods of determining the latent heats of water and of steam, and state what they respectively are.
7. Describe the process of percolation or displacement as applied to the preparation of tinctures, and point out conditions on which the successful application of the process depends.
8. Describe carbonic oxide and nitrous oxide, their composition, production, and properties.
9. What are the specific gravities of *Liquor Ammoniæ* and *Liquor Ammoniæ Fortior* of the Pharmacopœia, and what proportions of ammonia do they respectively contain?
10. How is hydriodic acid produced, in the form of gas, and also of liquid?
11. How is iron obtained in what is called the passive state, and what are the phenomena which characterize it in that state?
12. Describe the processes of the Pharmacopœia for the production of *Chloroform* and *Hydrochlorate of Morphia*, making any remarks that may occur to you in reference to them.
13. Give the formulæ representing the composition of the following bodies:—

    Carbolic acid.
    Gallic acid.
    Ammoniated mercury.
    Tartarated antimony.
    Borax.
    Alum.

The PRESIDENT then distributed the prizes to the successful candidates, and called upon Professor Bentley to state the result of the examination in the class of Botany and Materia Medica.

Professor BENTLEY said that he had always, at the commencement of a session, a difficult, but, at the same time, agreeable duty to discharge. Thus it was extremely difficult to find words to vary the uniform tenour of the observations which he had made on the conduct of the students of his class for the long period of twenty-three years during which he had been connected with the Society. But it was that which also made it an agreeable duty; for during the whole of that period he had had uniformly to speak of the regularity of attendance, good conduct, diligence, perseverance, and progress of, he might say, the large class which was entrusted to his care. That which he had always said he could repeat on the present occasion. In no previous session had he experienced more pleasure than he had done during the past year, both in that hall and in the garden of the Royal Botanic Society, in consequence of the general good conduct of the students. With these few brief words, which he hoped would be gratifying to those who had been unsuccessful, because, as his colleague (Dr. Redwood) had said, all could not be successful, he would now make a few remarks as to the prize examination. He was most gratified to say that, so far as his experience was concerned, the competition was altogether unprecedented. No less than thirteen candidates presented themselves to compete for honorary distinctions; and in order to show the great merit of those who competed, no less than nine gentlemen had, through his recommendation, been selected for honours by the Council. To give some idea of what those honours were, and to show that these gentlemen well deserved them, he would just state briefly what the rules of this Society were in relation to the award of these distinctions. No one was entitled to the silver medal unless he obtained over four-fifths of the marks,—that was, at least 80 marks out of 100; no one was recommended for the bronze medal or an honorary certificate unless he obtained three-fourths of the marks; and the certificate of merit was not awarded unless three-fifths of the marks had been gained. Those, therefore, who were not previously familiar with the examination in this Society would be able to form a true estimate of the distinctions which those students had obtained whose names he would read to them, and who would come forward to receive the prizes from the President. To all and every one he could say that they most thoroughly deserved the several distinctions to which they had become entitled. The first prize was the Silver Council Medal, which had been given to one who had already appeared before them to receive the Silver Medal in Chemistry and Pharmacy—Henry Churchill. The Bronze Medal was obtained by one who had well sustained the credit of that school, running very near to the Silver Medal list, and who bore a well-known name—Horace Davenport. Those who had obtained certificates of honour were Alexander Wood and Walter Benjamin Cole; and those who had obtained certificates of merit were Charles Arthur Overton, George Bult Francis, Thomas Iredale, Herbert Charles Webb, and Charles Alexander Blake.

The questions for examination were:—

Botany and Materia Medica.

BOTANY.

Hours: Ten till One.

1. Describe the general properties and structure of the cell-wall, and distinguish between parenchymatous and prosenchymatous cells.
2. Describe the structure of aerial leaves, and mention in what respect they differ from submersed leaves. Also state the distinctive characters between the leaves of Monocotyledonous and Dicotyledonous leaves.
3. Define the following:—Rhizome, tuber, parasite, epiphyte, conduplicate, reclinate, spadix, cyme, follicle, legume, pome, siliqua.
4. What is the seed? Describe its structure and mode of germination, and state the differences between the germination of the seeds of Monocotyledonous and Acotyledonous plants.
5. Give the essential characters of the following Natural Orders, and enumerate the officinal plants which they respectively contain:—*Cruciferæ*, *Umbelliferæ*, *Atropaceæ*, *Gentianaceæ*, *Iridaceæ* and *Liliaceæ*.

MATERIA MEDICA.

Hours: Two till Five.

1. Describe the method by which opium is obtained. State the characters of good opium, and mention the preparations in the British Pharmacopœia into which it enters as an ingredient.
2. How is aloes obtained in the greatest purity? Describe the distinctive characteristics of socotrine, hepatic and Barbadoes aloes.
3. What are the botanical and geographical sources of myrrh? Describe the physical and chemical characteristics of good myrrh, and enumerate the preparations in the British Pharmacopœia into which it enters as an ingredient.
4. What are the characters of the ordinary East Indian, Tinnivelly and Alexandrian kinds of senna? Mention their botanical and geographical sources, the substances usually employed to adulterate them, and the means of detecting such adulterations.
5. What are the botanical and geographical sources of the officinal and Savanilla kinds of rhatany? Show how they may be distinguished from each other; and mention the active constituents, medicinal properties and officinal preparations of rhatany.

The various prizes and certificates having been awarded to these gentlemen by the President, who accompanied them in most cases with suitable words of congratulation and encouragement, Professor Attfield made the following report on the class of Practical Chemistry:—

Professor Attfield said that he had nothing but good to report of the class of practical chemistry. To say this much was really to speak in high terms of praise of the students. For whereas his colleagues and teachers of lecture-classes generally could certify to the bodily presence and the outward behaviour of their pupils, and to the amount of knowledge possessed by a certain proportion at the end of a session, he and teachers of laboratory classes generally could testify, not only in these respects, but from daily and hourly observation, to the degree of ability and zeal displayed by every student. During the past year they have lived and laboured in the laboratory on the most perfect terms of harmony with each other. He himself, as well as his assistants, Dr. Tilden and Mr. Moss, had at all times found the students most ready to receive direct and indirect instruction, and willing, nay, anxious, to submit to periodical examination; instruction had thus been stimulated by examination, and examination by instruction, and the product had been, they trusted, a commensurate amount of education. And amongst the members of the class themselves, that free interchange of thought, mutual help, and frequent conversational testing of each other's progress, which is only possible to students working together under the same roof for a considerable period, had largely contributed to the general proficiency of each and all. The result had been that of the laboratory-students who during the year presented themselves before the Board of Examiners as candidates for the minor title of *Chemist and Druggist*, or the major title of *Pharmaceutical Chemist*, fewer than ever were plucked. Indeed, as a rule, he did not admit the possibility of a laboratory-student being rejected. There were, of course, exceptions to this rule. Unavoidable circumstances occasionally obliged a man prematurely to go up for examination; that man was surprised if he succeeded. Every year or two a student was met with in whom idleness and vice had drowned every trace of self-respect; when such failed to be sent back it would be time for the Council to pluck the Examiners. With these exceptions failure in the "Minor" or "Major" was most unusual on the part of a laboratory student. During the past session the entries in the practical class had reached 113; a higher number than that of any previous session. Moreover, for the first time, the laboratory class had been larger than either of the lecture classes. When the school was instituted, there was no laboratory class, the only method of instruction being that of lectures; afterwards means of prosecuting the study of chemistry by practical manipulation were provided, and ten gentlemen entered. In four years the numbers had risen to thirty, afterwards approaching, and last year exceeding the numbers attending lectures. Such a result, he thought, must be gratifying to those pioneers in pharmaceutical education who had striven to place this, the most thorough and effective method of learning chemistry at the disposal of students. Still there was abundance of room in the laboratory. Two years ago twelve new benches were added; and since the passing of the Pharmacy Bill of 1868 many students had worked for very short periods; hence if each one of the seventy-two benches were occupied as soon as empty, more than 200 gentlemen could be accommodated annually. When they might expect to reach this number he did not know, but his experience showed that practical chemistry was more studied every year, not only for its own sake, but as the quickest and best means of acquiring that knowledge of the principles of chemistry without which success in business became increasingly difficult, and success in passing the Minor and Major Examinations impossible. He had further to report respecting last session, not only that the conduct of the students was highly commendable, and that practical chemistry, as a branch of study, continued to increase in favour, but that the laboratory cost the Society nothing, it having about paid its expenses. At the close of the session nine gentlemen had competed for the prizes, conducting experiments with this object during two whole days. The tasks included operations in qualitative and quantitative analysis, and the value of perfect work was represented by the number 100. The extent to which the competitors severally approached this standard was indicated in the following table:—

Mr. Arthur P. Smith . . .	95
Mr. James Hughes	82
Mr. Henry Churchill . . .	79
Mr. Thomas Iredale . . .	73
Mr. Harold Woolley . . .	68
Mr. Herbert E. Constance .	66

The other three students obtained less than 60 marks—the minimum for honours. To Mr. Arthur P. Smith the Council had awarded an extra silver medal; extra, because Mr. Smith, being unconnected with the Pharmaceutical Society, or, indeed, with pharmacy, was, according to an old rule, scarcely eligible to compete for the medals. Mr. Smith was a most zealous and intelligent student; but through devotion to chemistry alone naturally was able to out-distance his fellow-students, who had to learn simultaneously three or four subjects. To prevent such non-pharmaceutical single-study men entering any class in the school, and running away with honours and prizes instituted for the encouragement of the harder-worked students in pharmacy, an order was made some years ago restricting the award of the medals, competition for the certificates remaining open. Under this rule Mr. Smith would only be able to take a certificate of honour of the first class; but considering, it was to be presumed, the unusually high merit of Mr. Smith's work, and that he would be likely to do credit to the School, the Council had kindly, and in the Professor's opinion wisely, given to Mr. Smith the much-coveted silver badge of excellence. Mr. James Hughes also having won a silver medal, was rewarded accordingly. Mr. Henry Churchill, the Junior Bell Scholar of last year, just missed the silver, but took a bronze medal. Messrs. Iredale, Woolley and Constance fully deserve their certificates of merit.

Practical Chemistry.

Hours: Ten to Five. Books and Memoranda permitted.
Standard Number of Marks, 100.

1. The substances supplied to you are five pharmacopœial chemicals. Name them.
2. Ascertain the nature of the impurities (if any) present in the accompanying salts.
3. The lozenges are supposed to be poisoned. Ascertain if such is the case.
4. A specimen of urine is placed before you; is it morbid or healthy?
5. The sample of "pyroligneous acid" contains some hydrochloric acid. Determine volumetrically the amount of each acid.
6. Analyse quantitatively the sample of Epsom salts. Give your results in percentages of Mg, SO_4, and H_2O.

P.S. You are at liberty to select one of the last two exercises, but not to attempt both. The same value in marks is attached to a correct answer in either.

The awards were then distributed to the respective successful competitors in this class.

Professor Bentley next stated the result of the competition for the Herbaria Prizes, remarking that he could not, although time pressed, refrain from doing justice to those who had competed for these distinctions. On the present occasion two collections had been forwarded for competition; and although he did not ask those present to examine them at that moment, yet he should like those interested in knowing what students could do to look at these collections before the close of the evening's proceedings. They all knew that these prizes were given for the best collections of British plants, and they were essentially competed for by young students of this Society, to whom they acted as a stimulus to the prosecution of a study which was not only important, practically, as bearing upon their future education and advancement as scientific pharmaceutists, but also as regarded their early training, in cultivating their powers of observation and discrimination. The two competitors on the present occasion were both deserving of distinction. He was particularly pleased to be able to state that the first was from a student who was only seventeen years of age, hence they would be able to appreciate the real merit which was due to him, and when he stated further that his name was Stoddart they would know that he bore an honoured name. The collection comprised between 500 and 600 plants, and when it was examined, he felt sure they would say that Mr. Walter Boycott Stoddart had honourably obtained the Bronze Medal. The second distinction which had been conferred was a certificate of honour to Augustus Horton Crundall, whose herbarium was also in the room, and he (Professor Bentley) could say that the student well deserved the distinction which he had obtained. The examples of these successful competitors would act as an inducement to other students to prosecute botanical studies during their apprenticeship, not only for the sake of botany itself, but also for the advantage it would give them as a training for their after studies.

The PRESIDENT then presented the Prize of Books for the best answers upon pharmacy and dispensing, remarking that they had been very deservedly awarded to Edward Rammell, who would no doubt make good use of the volumes.

The following were the questions for examination:—

PRIZE OF BOOKS.

DISPENSING AND PHARMACY.

Time allowed: Two Hours. Standard Number of Marks, 300.

State the best method of dispensing the following prescriptions, assign the reasons for the same, and write the labels in suitable language:—

℞ Ol. Ricini ℥j
Mucilag. Acaciæ q. s. (state quantity).
Syrup. Tolut. ʒvj
Liq. Potassæ ʒiss
Inf. Sennæ,
Aquæ Cinnam. ana part. æq. ad ℥vj.

Ft. mist., cujus capt. part. quart. primâ luce et repet. circiter meridiem, nisi alvus plenè dejecer.

℞ Acid. Carbolic. ʒss.
Pulv. Glycyrrh.
Pulv. Acaciæ ana q. s.

Ft. pil. xij, capt. j cum singulo cibo.

State the proportions of the ingredients in, and the method of preparing, the following decoctions,—cetrariæ, papaveris, taraxaci.

Describe and explain the P. B. process for making ext. ergotæ liquid.

Describe and explain the P. B. process for making syr. papaveris.

State the proportion of cantharides in each of the following preparations:—

Acetum Cantharidis.
Emplast. Calefaciens.
Emplast. Cantharidis.
Liquor Epispasticus.
Tinct. Cantharidis.
Ung. Cantharidis.

The PRESIDENT said that last but not least he had to present the Pereira Medal, the highest honour bestowed by the Society, which had been awarded to Henry Churchill.

The following were the questions for examination:—

PEREIRA MEDAL.

CHEMISTRY.

Time allowed: Two Hours. Standard Number of Marks, 100.

1. A solution acidified with hydrochloric acid gives a precipitate with sulphuretted hydrogen: what metals would you expect to find in the precipitate, and how would you *separate* each?
2. Describe the best methods of preparing the chief compounds of phosphorus with oxygen. State the physical and chemical properties of each.
3. Explain fully homology and isomerism.

Section I. BOTANY.

Standard Number of Marks, 100.

1. Give an account of the different kinds of placentation, illustrating each by an example.
2. Describe the flower of clover.
3. How does a *double chamomile* differ in structure from a *single chamomile*, and a *double rose* from a *single rose?*
4. What is the structure of the fruit in a fig and in a mulberry?

Section II. MATERIA MEDICA.

Standard Numbers of Marks, 100.

1. What is the structure of the minute glands which constitute *kamala ?*
2. What is the body that occasions the granular aspect of some kinds of tar,—what are its properties,—and should tar of such aspect be preferred for medicinal use?
3. Mention a recently-noticed adulteration of saffron, and explain how it may be readily detected.
4. Name the products of the Order *Lauraceæ*, used in food or medicine, state the plant by which (so far as is known) each is afforded, also the country of which native.

The PRESIDENT mentioned that the Council had been able to award three Bell scholarships this year. Unfortunately last year there was only one gentleman who gained a sufficient number of marks to be admitted a Bell scholar; but this year the competition was so good that the Council determined to give three Bell scholarships, as there was no senior.

The following were the questions for this Examination:—

JUNIOR BELL SCHOLARSHIP.

ARITHMETIC.

Time allowed: One Hour.

1. Write down in words at full length 25,642.
2. Write in figures the sum of ten thousand nine hundred and twenty-four.
3. Reduce $\frac{64}{128}$ to its lowest terms.
4. From $\frac{6}{7}$ take $\frac{4}{5}$.
5. If 10 men can do a piece of work in 8 days, how long will 4 men take to do the same?
6. Convert 4*d.*, 6*d.* and 8*d.* to the decimal of £1.
7. Multiply 154·321 by 100.
8. Divide 7·424 by ·32.
9. What is the cost of 186 yards of linen at 2*s.* 3*d.*?

LATIN.

Time allowed: One Hour.

1. Helvetii jam per angustias et fines Sequanorum suas copias transduxerant, et in Æduorum fines pervenerant eorumque agros populabantur. Ædui, quum se suaque ab iis defendere non possent, legatos ad Cæsarem mittunt rogatum auxilium: Ita se omni tempore de Populo Romano meritos esse, ut, pæne in conspectu exercitûs nostri, agri vastari, liberi eorum in servitutem abduci, oppida expugnari non debuerint. Eodem tempore Ambarri, necessarii et consanguinei Æduorum, Cæsarem certiorem faciunt, sese, depopulatis agris, non facilè ab oppidis vim hostium prohibere. Item Allobroges, qui trans Rhodanum vicos possessionesque habebant, fugâ se ad Cæsarem recipiunt, et demonstrant, sibi, præter agri solum, nihil esse reliqui. Quibus rebus adductus, Cæsar non expectandum sibi statuit, dum, omnibus fortunis sociorum consumtis, in Santonos Helvetii pervenirent.
2. State to what conjugation the verbs in this sentence belong.
3. Compare *pulcher*, *acer*, *multus* and *malus*.
4. Put into Latin, "To him death was but the gate of life."
5. What cases does *in* govern? and give examples.

ENGLISH COMPOSITION.

Time allowed: One Hour.

Write a few remarks upon one of the following subjects:—

Travel.
Study.

CHEMISTRY.

Time allowed: One Hour. Standard Number of Marks, 50.

1. Why are hydrogen and chlorine called chemical elements? What are the combining proportions by weight and by volume of these elements in hydrochloric acid gas?

2. How would you ascertain whether a specimen of an acid consisted of nitric or sulphuric acid?

3. Give a process for converting mercury into the mercurous and mercuric chlorides.

BOTANY.

Time allowed: One Hour. Standard Number of Marks, 50.

1. Explain the characters which distinguish *Endogens* from *Exogens*, and give examples of each.

2. Describe the structure and functions of a leaf.

3. Explain the meaning of the terms *ovule, fruit* and *seed*.

4. What is a rhizome, a tuber and a bulb?

MATERIA MEDICA.

Time allowed: One Hour. Standard Number of Marks, 50.

1. What are the principal bitter tonics used in medicine? Give, in each case, the name and Order of the plant.

2. What drugs are imported from the West Indian islands?

3. From what plants and what countries are the following obtained,—rhubarb, cinnamon, senega, orris root, matico and kamala?

4. What is the drug called *Podophyllin?* and how made?

The PRESIDENT then said: Having distributed the prizes and certificates, I cannot deny myself the gratification of saying a few words of congratulation and encouragement to the successful candidates collectively. Upon many previous occasions, with the exception of last year, it had been the custom to address a few words to each candidate, but I consider the plan adopted by Mr. Sandford preferable. Time is saved, which is important, now that we have an annual address, and the necessity of repeating similar words of approbation is avoided. My words will be few, but they will be earnest, heart-felt expressions of approval and encouragement. Most sincerely do I congratulate, not only you who have obtained the highest honours, but also you who have deservedly received certificates. All who run in a race cannot win, but they who have striven to the best of their abilities also merit praise and encouragement. Continue as you have commenced; still go on perseveringly, and you will carry joy, not only to the hearts of those who take the greatest interest in your well-doing, but you will win smiles of approbation from those in whom you take an interest. And let me say further, that during my short tenure of the presidential chair I have had no pleasure in connection therewith in any way commensurate with that which I have felt in distributing the prizes tonight. Although not a pupil in the ordinary sense of the word, I am still a pupil, and expect to be one unto the end; therefore, I take particular interest in all that concerns the young, and feel gratified by their success. Once more I say, remember that for the young there should be no such word as fail. Go on and prosper, and my best wishes go with you.

The following Inaugural Address was then delivered by Mr. JOHN MACKAY:—

MR. PRESIDENT, LADIES AND GENTLEMEN,

Three years ago a new feature was introduced in connection with the opening of the winter session in this school, so long and so successfully carried on, by the delivery of a few words of encouragement and advice to the young men about to commence their studies in pharmacy, chemistry and botany. Let me remark how singularly happy the idea was to invite the company of ladies on such an occasion, and how much the pleasure of all is enhanced by the presence of those fair friends who so kindly honour us by being now present. The plan thus inaugurated, after fair and repeated trials, has been pronounced a success. Nor can this be wondered at, for what is more pleasing to the youth about to buckle on his armour, than to hear and to know that many, whose names must indeed be familiar as household words, meet together, and by their presence on such an occasion prove that they still possess the deepest interest in the educational advancement and mental improvement of those who desire to make pharmacy their daily work and profession?

In connection with this movement, three gentlemen have already had the pleasure of addressing the pupils on similar occasions to the present; and I know there are many now hearing me who can testify to the ability and care with which they have so admirably fulfilled the trust committed to them.

Now it is this very fact which places me so awkwardly. I do not intend to analyse or characterize the nature or conclusions of the addresses which have preceded this one; but I feel constrained under the circumstances, and specially referring to these productions of the past, to say for myself, how extremely difficult I find it to follow those who have on former occasions so ably taken their place at this desk. I feel conscious that it is not an easy thing to stand on the same platform with the educated and scientific gentleman, from whose lips I heard, three years ago, a paper from the very appropriate motto "Thorough." Or, again, I would with all seriousness ask, is it not enough to make the boldest man falter when requested to follow in the wake of the eloquent, sensible and practical remarks of our venerable and venerated fellow-worker, Henry Deane? while it might appear an equally vain thing to imitate the poetic style of such an address as some of us heard a year ago within the walls of this very house. And yet, with all this, the feeling steals over me that, many years ago, obedience was so strongly inculcated that, when called upon by the Council of your Society to make my appearance before you this evening, I felt that it was my duty to come and undertake the task, with the strong impression, that the honour conferred by the invitation was not a slight one, and that, while I might fail to express in such graceful language or impart to what I might say the brightness and happiness which, like a golden thread, did so much to clothe, connect and enliven the brilliancy of the papers of those who had already addressed you, I could, at all events, as plainly, faithfully and sincerely wish the young students now before me God speed in their pursuits, and a successful and prosperous termination to their studies.

I honestly pity the man, be his age what it may, who has become so insensate and indifferent that he cannot now and then in some respects be a youth again. When memory fails to carry back to that early period when the world, with all its joys, sorrows and cares was practically unknown,—when the youthful mind revelled in the anticipations of a future career,—when the whole horizon of dawning hopes and fears was lighted up with the day-dream of happiness and success,—I say, when a man shuts his memory to such reminiscences, I feel he is in one sense to be pitied. Standing where I now do, I feel irresistibly carried back a few years, and I would be untrue to myself as well as to you did I not say so.

I can conceive of no one, having lived for half a century, who has not during that period forged and encircled himself by a chain of association which he would be unfair to himself and to others were he deliberately to break in pieces and cast aside, as if its component parts were only worthless material. I admit that throughout life's journey, with all the mutation which is not only a close but an inseparable companion, such a chain could not long exist unbroken, without here and there giving evidence of a shattered link; and it is while I now address you that such a flood of remembrance comes strong upon me, reminding of a peculiarly bright link in such a chain of association, which, to speak for a moment paradoxically, is in one sense truly broken, but in another as certainly not destroyed. I feel that I cannot stand before such an assemblage, in the house and within the walls of the Pharmaceutical Society, without at the very outset of these few remarks, adverting to him through whose noble disinterestedness, untiring energy, and vast intellectual power our very Society, of which we are so justly proud, was founded, nourished and extended. Need I say, I refer to the late Jacob Bell?

I feel that it is almost unnecessary for me to ask you to bear with me while in a single sentence or two I recall the time when, side by side with him who but a few years ago passed from among us, I followed my daily walk and occupation,—that period of my life on which I often love to dwell and linger, and which, while the heart throbs, will ever continue to be a bright-green and ever-to-be-remembered spot in my memory. It may be a story often told, and yet I cannot resist saying, especially to my young friends now present, that Jacob Bell was no ordinary man. With a mental capacity few possessed, a grasp of intellect rarely found, love for his neighbour which nothing could quench, a firmness of purpose at once irresistible, devoted to the herculean and apparently hopeless task of raising our profession, an amiability as conspicuous as it was untiring, in manner and conversation suited to grace any society, —Jacob Bell stood forward as the champion of all connected with pharmacy, and has thus earned for his memory, the unfailing and never-ending gratitude of the pharmaceutical body. I offer no apology for thus referring to our departed friend, for, although the very facts I have named of his varied mental acquirements render it vain to expect that in the present generation we will ever see his equal; yet, as it is the testimony of those who knew him best, that many years were spent, and life itself at last sacrificed, in his longing desire to benefit those around him, I do sincerely hope that such a good example may not be entirely lost, and that, unlike the morning cloud or early dew, which so soon pass away, the results of his labours may long remain and ever be remembered. For myself, I can conscientiously express the hope, that I may never live to see the day when the honoured and loved name of Jacob Bell will be otherwise than gratefully and affectionately remembered in such a meeting as the present.

It has been affirmed that real knowledge is difficult to attain, and yet that, to many in the pursuit of it, the subject assumes three aspects or distinct phases. At the very outset the young and eager student thinks all so easy as almost to be within his grasp; or, at all events, at the very threshold of investigation, the atmosphere appears so clear and bright that the path he has to travel can scarcely be mistaken, and to his mental vision easy and soon to be traversed. Soon, however, comes the next stage, when, having fairly grappled the first difficulty, he finds he knows comparatively nothing; and with such a feeling, accompanied by a noble and determined effort to acquire the desired and necessary information to fit him for his future career, comes the third condition or phase, that of perfect conception and rapid acquisition of the real knowledge sought for.

Many who have prosecuted study and research will admit that, in many cases, there is considerable truth in this statement, while the description may be looked upon by others as fanciful and figurative; yet it cannot be denied that in no profession is such a state of gradual advancement so apparent as in our own. To many the first step in chemistry and pharmacy seems simple and easy, and yet how rapidly comes the time when the peculiarities and depths of the sciences require our closest attention and study, before we can comprehend either their marvels, harmonies, or truths! It is, indeed, correct when we say there is no royal road to knowledge, and we who are pharmacists form no exception to this unvarying rule. Let me then, in view of this fact, impress upon you all the value of time. During no period of life is it more difficult to realize this than in youth. I know that five minutes or half an hour spent in a light frivolous manner is thought nothing of by many a young student. I know well that fatigue will often plead, and that powerfully, for rest and amusement; but I go further, and say, relaxation is not only useful, but a necessity. What I ask for is not the abuse, but the use, of spare minutes and hours. As Martin Tupper has it,—

> "If the mind is wearied by study, or the body worn with sickness,
> It is well to lie fallow for a while, in the vacancy of sheer amusement;
> But when thou prosperest in health, and thine intellect can soar untired,
> To seek uninstructive pleasure is to slumber on the couch of indolence."

The real life of every pharmaceutist may be said to be divided into two stages or divisions. The first can be recognized as the period during which a young man ought to learn and acquire a solid foundation on which to depend for his future success; while the other may be said to embrace the more extended period during which he will be called upon to exercise or apply the information gained by study and application to the circumstances of his position, and thus turn to some useful account the study of past years. No young student ought, therefore, ever to forget—

> "This above all, to thine own self be true,
> And it must follow, as night the day,
> Thou canst not then be false to any man."

Above all, be true each one to himself in this respect, that he feels and acts as if he knew, that it is essentially necessary to keep up the stock of knowledge already gained by the maintenance, more or less, of habits of investigation and study; for at the present time it is impossible for any one to take his true position as an educated pharmacist, unless he diligently keeps himself abreast in all that pertains to pharmaceutical chemistry. I know that in making this statement I lay myself open to the remark, that in many cases the opportunities for self-improvement are so few, and the means of cultivating the scientific department of our business so meagre, that it is almost impossible to evoke from odd minutes or even hours such results as those at which I have hinted. But to meet such a feeling, may I not refer to cases where the most brilliant talent has, after being clouded and hid amidst difficulties and struggles, emerged and shone with dazzling lustre in the horizon of science. It has been surmised that Sir Humphry Davy would never have been the great philosopher he became had he been favoured with extensive privileges in his early career, and that the discipline through which he was compelled to pass, owing to his comparative poverty, developed the perseverance and energy so necessary in his future researches to raise him to a pinnacle of fame few in the world ever reached. But to go a step further, it is known that the late Professor Faraday, pupil and successor to the illustrious Davy, being of very humble parentage, was, at the early age of thirteen, apprenticed to a bookbinder, and while following this his intended occupation, was found one day reading an article on electricity in a volume of the 'Encyclopædia Britannica,' which had been sent to be bound. The gentleman to whom the book belonged, on making this discovery, was so much struck, that he presented Faraday with a ticket to attend Davy's lectures at the Royal Institution, soon after which he was admitted to a place in the philosopher's laboratory, and reached, as you all know, long before his death, a world-wide renown and reputation.

Of these two great men it has been said, "Both were greater because of their first difficulties; but they were greater because they had the mental constitution which required such difficulties to brace their power. Had they been originally men of ordinary mental gifts, they would have remained until death in their original obscurity. Had they, in common with their great mental endowments, possessed unlimited facilities, they might never have passed the bounds of a respectable mediocrity."

I cannot, therefore, impress too strongly upon all the great importance of a just appreciation of the value of time. Every man is apt to waste or misspend time; and we know, if once lost, it can never be regained. We can measure its flight, but we cannot, for a single moment, arrest its onward progress; onward, onward, since the world began; and on, unceasingly on, until the period when time itself shall be no more. The child of yesterday becomes the man of to-day; and if such be the unceasing and rapid flight of time, it certainly becomes all important to economize and use the precious and never-to-be-recalled minutes ere they flit for ever away. Well has Marsden put it when he says,—

"'What is time?'
I asked an aged man,—a man of cares,
Wrinkled and curved, and white with hoary hairs;
'Time is the warp of life,' he said; 'O tell
The young, the fair, the gay, to weave it well.'"

I know it is not an easy thing for the youthful mind to realize, in all its fulness, the value of time. There are so many allurements, so many whisperings, and so many attractions, that the mind is frequently insensibly led away, until, when the opportunity is over and the day far spent, regret and disquiet creep in, where all might have been peace and satisfaction. How often in mental review does the man of riper years wander back to time which has passed like a vision, and with such remembrances find what might have been otherwise a pleasing picture, so blurred and defaced, that pain, humiliation and vexation are all the more intensified from the few bright and beautiful spots which, like "apples of gold in a picture of silver," may be seen struggling through the gloom, carrying the conviction that many opportunities had been lost which might have been turned to useful account, but now gone for ever!

I make these statements very plainly and boldly, because I believe I am right in believing that there is no one now hearing me, for whom these remarks are specially intended, who has not a brief space of unoccupied time more or less on his hands; and I wish to draw the particular attention of all such to the full value of spare minutes, and to inculcate the amount of good to be done by a methodical and systematic arrangement of the short half-hour in the morning, evening, after meals, or, indeed, at any time of the day or night. I have a very pleasing recollection of what could be done in our own business at a period when hours of attendance were very much longer than at present. During my residence in 338, Oxford Street, not one minute was lost at breakfast, dinner, or tea. Each young man had his book on the table; while the evenings after 10, or even 11, o'clock were devoted to reading and study. More than myself are now alive to testify to the good results arising from such organization; and few things afford me greater pleasure than in recognizing, while I now address you, a living witness of the truth of what I have just stated, in the person of my old, tried, and valued friend, Mr. Hills, in himself a type of all that is good, generous, and amiable; and who, I am proud to say, was my fellow-companion during the whole time I was in Mr. Bell's establishment.

With a view to impress still further upon my young friends the inestimable value of time, I cannot resist introducing a picture which I feel assured will interest all, namely, a glance at the early years of the life of an eminent and excellent man; who, while in this world, so measured and arranged his time, that he greatly advanced the temporal and spiritual good of many of his fellow-creatures, and whose life and actions we may well strive not only to admire, but, in many respects, to imitate.

About ninety years ago there lived in Spitalfields a silk manufacturer. I must ask you, in imagination, to accompany me to his mansion, and wending our way upstairs into a boy's apartment, there find an inmate in the form of a youth about fourteen years old. This young boy is not idle; he has evidently head and hands employed. He is endeavouring to make some tubular instrument, the materials employed being card-board and glass. He is trying to make a telescope. Money to purchase one, or even better materials with which to attempt its construction, were not within his reach; but yet a telescope he must have. Accordingly, he may have paid one shilling for glass, and twopence for pasteboard, and with these he is busy at work. He proceeds without intermission; and when night has canopied the restless city and stilled its noonday roar into a murmur, and when its countless stars are keeping watch over the homes of men, you will see our young friend has succeeded; there, at his open window, he may be seen with his recently and economically made instrument pointed heavenward, his young eye, as sleepless as the objects to which his gaze is so earnestly directed, seems fixed to the other end, when, suddenly springing from the window, he exclaims, in perfect ecstasy, "I see them! I see them." He had thus early discovered the movements of Jupiter. A glance round the room showed abundance of chemical as well as astronomical proclivities; and, although it was his father's strong desire to bind him among the silken meshes of his own occupation, he became one of our most celebrated chemists, devoting his life not only to the varied pursuits of science, but also in a persistent endeavour to benefit the temporal and spiritual condition of his fellow-creatures. And who do you imagine this loving, able, and talented man was? No other than the first President of our Society, the gentle, amiable, kind and good man William Allen. Need I tell that the boy I have described became the founder of a philosophical society?—lecturer at one of the hospitals in the metropolis;—the intimate friend of Sir Astley Cooper;—the companion of the well-known Humphry Davy;—associated with Dr. Jenner in his great discovery;—and aiding and assisting not a little the celebrated Wilberforce in abolishing the slave trade.

All honour to this noble man's example, whose labours for the benefit and amelioration of his fellow-creatures were such as to carry his name and reputation far beyond the shores of his native country, and whose memory is yet honoured by many at home and abroad who have been privileged to know the time he spent, and the success which attended his unceasing and earnest efforts for the benefit of mankind.

So much for the unselfish life of a pharmaceutist, of, I am proud to say, one of ourselves, whose career, at once so brilliant and so remarkable, may well stand out as a beacon-light to warn from idleness and inattention, and, at the same time act as an inducement to make such use of time and talents, to the extent we are able, that a review of days and years passed away may give—mingled, it may be, with some regret—a feeling that our whole existence has not passed without more than one effort on our part to improve, both to ourselves and others, the opportunities afforded us. True, every one cannot be Jacob Bells or William Allens, for

> "All are not born
> To touch majestic eminence and shine."

But I beg you to remember that no man living, and particularly no one connected with us in our daily walk, can fail, if he is so disposed, to improve himself, and benefit, in some degree, those around him. Though no single individual can unaided rear a structure, still many a stone may be placed in position, and thus assist, in some measure, the building up of what may be looked upon with satisfaction. I am one of those who believe we all have our mission, and that our duty, in whatever sphere we may be placed, is to do our best; and thus acting, we are told "Angels can no more;" while such exertions will, and ought, to carry with them a feeling of happiness and comfort.

Throughout your student-life then avoid being selfish. Do not live entirely to yourselves, or simply for your own gratification or pleasure,—and allow me to add, that in emerging from the life of a student, let the man be as determined as the boy, not to live to himself, but view opportunities given for being of service to others, a great and high privilege which he can never over-estimate or value too highly. I do trust that in making these statements I am not misunderstood. I am a believer in what has been often quoted, "to know that before us lies in daily life is the prime wisdom," and I therefore do not in the least degree argue inattention to daily engagements and other claims, which every man in business must know and feel to be imperative; but as you mix in the world you will find human nature often difficult to understand or comprehend, and witness its inner promptings sometimes issue in anything but a pleasing aspect; and although it may be a comparatively rare thing for you to fall in with self-sacrificing individuals, yet trust me when I tell you, that as you journey on through life, and as year after year flits away, like milestones along the highway, reminding that though slowly you are surely treading the path which must at last end your journey, there can be no more pleasing or agreeable thought than the consciousness of having contributed, when opportunity offered, to the instruction, relief, or comfort of neighbour or friend.

I know much has been said and written, and that a strong feeling exists in the youthful mind in regard to a subject to which time will only permit me to glance, namely, early closing. I have always been, and still am, an advocate for this whenever it can be accomplished. It is undeniable that late hours in our business are in many instances the result of bad habits, and we know how difficult these are to eradicate. The aspect of many things has changed of late years, and in many towns and numerous districts, the general public have become educated to a change in this bad custom, and therefore many dispensing establishments now close at 8 o'clock instead of keeping open until a much later hour. Indeed, although there may be, and are, many exceptions, still I believe that with the chemist and druggist the iron age of late hours and slavish attention to business is rapidly passing, and that we are gradually approaching the golden age of pharmaceutical position. I would, however, say to all young men now present, that there may be particular districts, and very special reasons for some places of business keeping open till a late hour in the evening, and where, from a calm and dispassionate view of these circumstances, it is found to be a necessity, there should not be the expressions of disappointment, irritation and vexation which I know are now and then pretty forcibly expressed, but rather let there be an attempt made by constitutional means to bring about, if possible, a better state of things. I confess it is almost ludicrous to find that if from accidental circumstances, such as stock-taking, painting, etc., a druggist's shop chances to be kept open unusually late, you are certain to have parties coming in for certainly no very urgent medicine, but simply because the door was observed open, or the light visible. Sudden recollection coming then upon them, the most ordinary household medicine became an immediate necessity. Now this is not as it ought to be; and no one will be more satisfied than I will be, to know, that throughout the length and breadth of the land, dispensing chemists follow the good example of many of their brethren, and shut at such an hour in the evening, as will allow the young man to retire to his room for study, or to take some recreation, or what is better still, a portion of both.

A word or two as to your position here as students of this school. Many young men in the provinces have a feeling of disappointment and jealousy as to the great advantages which those who reside in London or neighbourhood find in Bloomsbury Square. I admit at once there is at first sight some foundation for such a feeling, for comparatively few can come from a distance to study in London. But I cannot help thinking that ere long this Society will cease to be an educating body. No one need start or look amazed under the impression that I am about to consign your able and eloquent professors and teachers to oblivion. My intention is very far from that, for I say all honour to those distinguished and tried men who have done so much for the existing race of pharmaceutists, and whose successful labours may yet, I hope, extend through many succeeding years. But be it remembered, we are now recognized by Government as an examining body, and it is certainly not unreasonable we should cease to be an educating one also. I fancy therefore that ere long the Society will neither appoint nor pay professors. Already it is understood that a young man may obtain the knowledge required to enable him to become associate or member in any way he pleases; and so, in like manner, I look forward to the time, not far distant, when in London or in the provinces, young men will attend lectures, as well as practical chemistry, without being taken under the wing of the Society; and thus that the existing course of study in the Square will be succeeded by lectures and lecturers more in accordance with an established college of pharmacy. I admit at once that a centre must exist somewhere, and for many reasons there is no place so well fitted for this as the metropolis. Never forget, however, that by study and application pharmacy and its kindred subjects are capable of being learned and comprehended in the country village as well as in the crowded town; and if not quite so easily and readily acquired, as when guided by eminent teachers, the merit of accomplishing the arduous task is all the greater, when in the absence of such opportunities a position can be gained in London or elsewhere.

It is neither the time nor the place to refer to the troubled waters of pharmaceutical legislation, nor will I make any remark as to the surging waves of fear and anxiety which have of late passed over the horizon of poison regulations and responsibilities; but I may remark, that in any approach we may make to Government, the keynote of our advanced position and recognition is so loudly sounded, that the eye of the general public turns more observantly than ever on our movements, and it therefore becomes us all to proceed with the greatest circumspection in all that pertains to the carrying out of existing Acts of Parliament; and while there are many good men and true standing in the breach, succeeding generations look to those who, like many now before me, will gradually but surely follow in the footsteps of those to whom they at present look up as their seniors. Again, then, let me urge upon you application and study. Never be discouraged with any difficulty. Ever remember there is much in these two short simple words, "Try again!" for I know no feeling more pleasing to a young man, than that of a sense of victory after more than one hard struggle to overcome what had appeared not only difficult, but almost insurmountable.

In conclusion, let me remind you that in connection with the varied course of study upon which you are about to enter, the science of chemistry very specially presents a wide and extensive field from which to cull many interesting facts. I feel that I have lived long enough to know that the comparatively finished chemist of to-day may become the humble and eager student of to-morrow, for amidst the more than giant strides with which chemical science has been, and is still advancing, it takes a great amount of labour, study and research to follow in the path of chemical investigation. What, may I ask, can be said of that science which, while it includes more or less the whole range of sublunary things, starts through the immensity of space, bringing you into acquaintance with the very materials of which the planetary system itself consists? Nay, invades the light of the sun, and tells that in the rays of the luminous orb of day there are found materials and compounds not only in great variety, but rivalling in value the diamond itself, thus giving unmistakable proof, that far away in the twinkling star, or soft silvery moon, and in the bright blazing sun, we have chemical elements in varied combinations, playing important parts, and giving rise to a wonderful and harmonious whole! Need I refer to spectrum analysis, electricity, dialysis, and kindred discoveries, as assisting to open the mysterious and hitherto unopened marvels and wonders of creation? While, however, surprise and amazement may be excited, let us never forget, that amidst the endless and never-wearying changes going on, the most minute, as well as the most stupendous work in the heavens above, or on the earth beneath, whether indeed it be the falling of the sparrow to the ground,—clothing the flower in all its gorgeous beauty,—raising the gigantic tree of the forest,—governing the stormy wind or wild ocean wave,—supplying the germ of vitality to the most tiny form of animal or vegetable life,—supporting the daily, if not the momentary wants of all existing things, is yet the ever kind, loving and beneficent Creator, who "has measured the waters in the hollow of his hand, meted out the heavens with the span, comprehended the dust of the earth in a measure, weighed the mountains in scales, and the hills in a balance, and who taketh up the isles as a very little thing."

The President was quite certain they would be very much dissatisfied if he closed that meeting without expressing their thanks and his own to Mr. Mackay for his very excellent address. Although at its commencement Mr. Mackay was willing to make them believe that he should fall somewhat short, he fairly proved in the end that

"Whether doing, suffering, or forbearing,
We may do much by persevering."

The Chairman announced that the next evening meeting would be held on Wednesday, November 1st.

Provincial Transactions.

TYNESIDE CHEMISTS' ASSISTANTS' ASSOCIATION.

The Inaugural Meeting of this Association was held on Thursday evening, the 21st of September, in the Museum of the Natural History Society.

The President (Mr. Shaw), in commencing his address, stated that on coming to Newcastle a few months ago, a perfect stranger to the locality, he had regretted that there was no place in the town to which he, in common with his brethren of the trade, could resort for the purpose of social intercourse and interchange of sentiment on matters connected with their calling; the hint, he continued, was taken up by a few who had similar views, and the hope entertained that such meetings periodically held would form not only pleasant social reunions, but also that opportunities would then be afforded for practical improvement, and that thus, whether in the capacity of assistant or apprentice, a bond of unity for mental improvement and encouragement might be cemented to their own great advantage, the satisfaction of their employers, and the good of the public at large. The President then proceeded to say that the special business of the Society's meetings would be the reading of papers on subjects connected directly or indirectly with pharmacy, and the promotion of free discussion thereon, and he believed that such interchange of opinion would tend materially to help the younger members in preparing for the necessary pharmaceutical examinations.

A room has been taken for the meetings of the Association, which will be open to members every evening except Saturday and Sunday; hither they may resort to spend a quiet hour in reading or study, and here the ordinary meetings of the Society will be fortnightly held. It is intended, as soon as funds will permit, to commence a library and museum. Already a valuable collection of specimens of materia medica has been kindly presented by Messrs. Southall, Son and Dymond, of Birmingham. We indulge the hope that this liberal contribution may lead our neighbours to lend a helping hand in an undertaking which cannot fail to commend itself to the good feeling of the community.

The Secretary (Mr. Alfred Brady), in a few cursory remarks, stated that it was proposed to place on their tables some of the periodical publications more immediately connected with chemical, pharmaceutical, and medical science, for the perusal of their members; and concluded by assuring the younger members of the Association that the earnest desire of the committee was to render them every aid that their position would admit.

A medical gentleman was present at this meeting, and dropped a few words of encouragement to those who had but newly entered on their career, urging them to meet courageously the little difficulties which must needs arise in their elementary training; and assuring them that, after having by close study surmounted these, their future course would be comparatively easy and pleasant.

A cordial vote of thanks was accorded to this gentleman for his advocacy, and to the President.

The meeting was brought to a close by the Secretary reading a paper on "Alchemy, the Cradle of Chemistry," which was listened to with great attention and interest.

The number of members already enrolled is upwards of fifty.

THE MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

A circular has been issued by Mr. Joseph Lucas and Mr. Walter R. Jones, Honorary Secretaries of the Midland Counties Chemists' Association, calling the attention of the Chemists' Assistants and Apprentices of Birmingham and the Midland Counties to the following classes, at the Birmingham and Midland Institute, as being those which are likely to be most useful to candidates preparing for the examinations of the Pharmaceutical Society.

Arithmetic, Mondays and Wednesdays, 8 p.m.—Fee, one penny a lesson.

Botany (Vegetable Anatomy, and Physiology), Wednesdays, 8 p.m.—Fee, 3*s*. 6*d*. a term.

Elementary Chemistry, Tuesdays, 8 p.m.—Fee, one penny a lesson.

English Grammar and Composition, Thursdays, 8 p.m. —Fee, 3*s*. 6*d*. a term.

Latin, Mondays, 7.30 p.m.—Fee, 3*s*. 6*d*. a term.

Practical Chemistry, Fridays, 7 to 10 p.m.—Fee, 10*s*. a term; Saturdays, 3 to 6 p.m.—Fee, 10*s*. a term; Saturdays, 6.30 to 9.30 p.m.—Fee, 10*s*. a term.

There are 30 lessons in each class during the session, which is divided into two terms, of 15 lessons each.

The following arrangements have been made with the Council of the Institute, for special facilities being given during the present session, to chemists preparing for the above-named examinations.

In the elementary chemistry class, a special lesson will be given from 9 to 10 p.m., on the first Tuesday in each month, to those students who desire to prepare for the examinations of the Pharmaceutical Society, who will pledge themselves to attend 25 of the ordinary class lessons in elementary chemistry at 8 p.m., during the present session, and to sit at the examination in that subject, which will be held by the Science and Art Department in May next. These lessons will be especially framed to meet the requirements of the examiners for the Pharmaceutical Society. As no extra fee will be charged to those students who avail themselves of these lessons, it will be understood that all who attend them undertake to comply faithfully with the above conditions.

In the practical chemistry class, the course of instruction, to those who require it, will be specially arranged for the same purpose. As each student will work independently, he may begin a course of study at any date.

All necessary materials will be provided for the course of instruction given.

Each student will be provided with a working bench, fitted with drawers and cupboards, for the apparatus, etc. with which he is supplied, and for the safe keeping and restoration of which he is held responsible on leaving the class. He will be required to pay a deposit of 2*s*. 6*d*. in addition to his fee, which will be returned to him at the end of the session, less any sum which may be charged to him for breakage of apparatus, or for the cleaning of any apparatus which he may have neglected.

All students who are admitted to the practical chemistry class, at the fee above-named, will also be required to comply with the conditions as to number of lessons, and attendance at examination in elementary chemistry, referred to in the paragraph relating to the latter subject.

In the Latin class, a special lesson will be given at 8 p.m., on the first Thursday in each month, for the purpose of reading with the student the works of the Latin author required at these examinations.

In the other classes, the course of study already includes the subjects required for the examinations.

The fees to the above classes must be paid to Mr. J. Lucas, 4, Colmore Row, or to Mr. Edwin Smith, Secretary of the Institute, Ratcliffe Place, Paradise Street, any day from 10 a.m. to 5 p.m., except on Saturday.

The fees to the penny classes are paid at the doors of the Institute, or books containing tickets of admission to six lessons, price 6*d*. each, may be obtained at the Institute.

Arrangements will be made, in those classes where it is found necessary, for extra lessons during the session to those students who join at once, in order that they

The text-books used in the classes will be those adapted to the object in view, and will be selected after consultation with the teachers.

Mr. Woodward will also give a special lesson to the members of the Chemists' Association, at 7 p.m. on Tuesday, the 10th of October, in order to explain to them the course of instruction which will be followed in the class.

If these arrangements should prove to be successful in the object for which they are designed, it is probable that the Council of the Institute will give further facilities to candidates for these examinations before the beginning of the session of 1872. They will also make such changes in the arrangements now proposed, as may be found by experience to be for the benefit of the students who avail themselves of the system now introduced.

Parliamentary and Law Proceedings.

Poisoning by Nitric Acid.

On Friday, September 29, Mr. Langham held an inquest at Westminster Hospital on the body of William Collin, aged nine years, who resided with his parents at Peabody Square, Victoria Street. On Tuesday evening previous a young man, a friend of the family, was in the parlour, making experiments with a galvanic battery, and on the table were two ginger-beer bottles filled with nitric acid. While the young man was engaged in attending to the battery, the deceased, unperceived by any person, came into the room, and, taking up one of the bottles from the table, drank a large portion of the contents. He fell to the floor shrieking with agony, which was the first intimation of his being in the room. He was at once taken off to the hospital, where every possible attention was paid to him, but he died in a short time in a state of indescribable agony. A verdict was returned that deceased was accidentally poisoned by drinking nitric acid.

A Child Poisoned by Strychnia.

Dr. Lankester, the coroner for Central Middlesex, yesterday held an inquest at the 'Stag's Head,' Hawley Road, Kentish Town, on the body of Mary Kate Rowbotham, aged two and a half years, infant daughter of Mr. Samuel Rowbotham, an author.

Mr. Samuel Rowbotham said he was a writer on chemistry and scientific matters, and father of deceased. A short time ago he had a son at school in Kent who suffered from skin disease. He had the child home, and to cure him, intended to apply some strychnine, taking some out of his medicine chest, which he had kept by him over twenty years, and putting it on the mantelshelf. On Thursday last the 28th ult., while engaged on a work which he had to get finished in a given time, his wife asked him to give deceased a dose of henbane. He got up abstractedly, and, as he thought, did so, placing the bottle back on the mantelshelf, when his little son said, "Oh, papa, give me some, I like it." He poured out ten drops, when the boy said, "Oh, papa, I don't like this." He then looked at the bottle (an ordinary common bottle) and was horror-struck to find he had taken the wrong bottle.

Dr. C. F. Groom, said on proceeding to the house he found deceased suffering from lockjaw. He gave an emetic, but deceased expired in ten minutes. The cause of death was poisoning by strychnine.

The coroner, remarking on the lamentable nature of the case, said this was another to be added to the list of deaths from poisoning caused by keeping dangerous fluids in common bottles. He had over and over again warned the public of the dangers they run in so doing, and had recommended that all poisonous matters should be kept in conical bottles, because then the moment the bottle was touched it would be known as a bottle containing poison. He hoped that the public would see the force of this, and adopt this simple means of putting a stop to such accidents.

The bottle containing the strychnine mixed with vinegar was here handed to the jury to examine, when the foreman, instead of smelling the cork, placed the mouth of the bottle to his lips to taste the mixture, and to the astonishment of those present would have taken more than was good for him had it not been for the speedy caution of the coroner.

The jury returned a verdict of "Death by misadventure."—*Standard.*

A Caution to Druggists.

At the Birkenhead Police Court on Saturday, Sept. 30, before Mr. Preston, a man, named James Craig, a labourer, living at 262, Price Street, was brought up in custody, charged with attempting to commit suicide by taking poison.

Ann Tickle, a young girl, lodging in the same house as the prisoner and his wife, said that on Friday evening the former sent her to the shop of Mr. Reece, druggist, 239, Price Street, for sixpennyworth of laudanum. He told her if the druggist asked her what it was for she was to reply that it was for a horse. She obtained the drug, and gave it to the prisoner, whom she then saw mix it with a gill of ale, which he took upstairs to his own room; she did not observe him come down again, and soon afterwards she was told that he had poisoned himself.

The prisoner's wife said, that on Friday evening her husband made an excuse to obtain her absence. When she returned she found him in a state of stupefaction, but not unconscious, and able to deny that he had swallowed any poison; she, however, saw a cup beside him, which smelt as if it had contained laudanum.

Dr. Vacher, the house surgeon of the borough hospital, said that he received the prisoner on Friday evening, the man being then in a deep sleep, and under the influence of opium. He was now out of danger.

Mr. John Reece, the druggist, was called. He said that the girl Tickle came to him for sixpennyworth of laudanum, which she said was for a horse, and without any distrust he gave her an ounce, the same thing having occurred on the previous day.

Dr. Vacher here said that an ounce was more than enough to poison any man.

The magistrate asked Mr. Reece if he was not aware that he should not sell poison in that manner, and without due precautions as required by law.

Mr. Reece reiterated that he did not mistrust the girl, on account of the same thing having occurred on the previous day, and nothing wrong having come of it.

The magistrate said to the druggist, that he had rendered himself liable to a penalty of £5 for not complying with the regulations of the Act of Parliament; he ought not to have sold poison to a child like the girl Tickle. He (the magistrate) did not know whether any proceedings would be taken against him (Reece)—that would be seen hereafter. The witness had been very blamable in the matter; he ought not to have sold poison to any person unknown to himself, or who was unaccompanied by some person whom he did know.

In answer to the magistrate, the prisoner's wife said that the poison was not sent by the druggist in a bottle, but in a cup, which, however, was labelled "poison."

Mr. Preston cautioned Mr. Reece to be more careful for the future; the prisoner might have lost his life through his carelessness, in which event he (Reece) would have been in a very unpleasant position.

Mr. Preston remanded the prisoner, to ascertain how his recovery progresses.—*Liverpool Daily Post.*

Tincture Presses.

Sir,—About this time last year, I published in the columns of your Journal (Pharm. Journ. 1870, p. 321) a table of results which had been obtained when hydraulic pressure was used, for the recovery of spirit from the marcs of the various tinctures of the British Pharmacopœia.

At that time some of your correspondents thought the matter worthy of further attention; and from several pharmacists, who had compared my results with those they had been in the habit of obtaining with the ordinary tincture press, I received inquiries. The question most frequently asked was, "What would be the cost of a small hydraulic press that could be used for the removal of the spirit from the marc of about one or two gallons of tincture?"

Upon making inquiry, I found that not only were the smallest presses that hydraulic engineers were accustomed to make, much too large for a small pharmaceutical laboratory, but that the cost was so excessive, as compared with that of the usual press, that the extra outlay would not have repaid the purchaser, even if he could have recovered an additional *ten* per cent. of alcohol, over and above the quantity that he had been in the habit of obtaining, with the ordinary screw press.

The editorial reference in your issue of September 16th to *hydraulic tincture presses* again brings the subject before us; and I, for one, am anxiously looking forward to the description of the press you have promised to place before the readers of the Journal.

In the meantime, I think we cannot be better occupied than by making ourselves thoroughly acquainted with *the power* and merits of our old friend the screw tincture press. This done, we shall be in a better position to judge of the qualities of the improved machine that you purpose describing.

I here allude to the power more especially, because I think that very exaggerated notions are formed of the capabilities of the ordinary laboratory tincture press. For instance, we were recently told by Mr. Staples (who, by the way, is a pattern to us in the manner in which he applies his engineering skill to pharmaceutical requirements), at the British Pharmaceutical Conference at Edinburgh (Pharm. Journ. Sept. 9, 214), that the pressure obtained in the tincture press, as ordinarily met with, was nearly *twenty tons*. Now, without making any remarks upon the merits of the press as designed by Mr. Staples, an illustration of which appeared in your Journal, and upon which one of your correspondents has since commented, I should like, with your permission, to bring forward facts in support of the statement I have made, and I will do so by the following illustrations. (Before, however, doing so, it will be only just to say that Mr. Staples remarks in his communication "it may be objected that these figures are somewhat theoretical)":—I have in use two presses; the one (*a*) is rather old-fashioned, but very strongly made, and of a capacity of one gallon; such an one, I imagine, would be found in many a country pharmacy; the other (*b*) is one of more recent date, of about the same size (Lynch and Co., Aldersgate Street, E.C., makers). The mechanical advantages in the use of either of these can easily be deduced from the following; *as the circumference of the circle described by the lever where the power acts is to the pitch of the screw, so is the force applied to the resistance:*—

(*a*) Lever 10 inches.
Pitch of screw $\frac{5}{16}$ inch (·312).
Force applied at extremity of lever 50 lb.

Then $\dfrac{10 \times 2 \times 3{\cdot}1416 \times 50}{{\cdot}312} = 10532$ lb.
or about $4\frac{3}{4}$ tons (theoretically).

(*b*) Lever 8·5 inches.
Pitch of screw $\frac{1}{4}$ inch (·25)
Force applied at extremity of lever 50 lb.

Then $\dfrac{8{\cdot}5 \times 2 \times 3{\cdot}1416 \times 5}{{\cdot}25} = 10681$ lb.
or about $4\frac{3}{4}$ tons. (theoretically).

In these calculations it will be seen that the amount of force applied to the end of the lever is only half that upon which Mr. Staples has based his calculations. The lever, too, in both presses is somewhat shorter, while the pitch of the screw is materially larger in both, in one case being nearly twice the size. Now as I have ascertained that these measures given, accurately represent the various dimensions of the tincture presses of trade, which can be verified by a visit to any druggists' sundriesman's store in this city, it remains for me to give a reason, why I prefer to take 50 pounds as the force applied at the extremity of the lever rather than 100 pounds.

Upon reference to a work by Professor Rankine, I found that the average force applied by a man at the end of a lever, in such a position as met with in the tincture press (he instances pulling an oar), was 26·5 lb., and while working a crank 20 lb. It cannot, therefore, be said that in nearly doubling this amount, as I have done, my calculation has been taken upon a minimum power, but rather in excess of the true maximum one.

A little reflection will show, that the power exerted by a man in the position required for the motion of the tincture press lever is very different to the raising of a weight from the ground, in which additional muscles are brought into play.

It must always be remembered that when the screw is loaded, the friction to be overcome is something considerable; and for this reason, I have termed the results obtained by the above calculations as *theoretical;* for in order to obtain an exact idea of the real pressure exerted, a deduction of at least 30 per cent. must be made from the calculated pressure.

I think, therefore, that if the power obtained in the ordinary 1 gallon screw tincture press be computed to be *two tons* (as a maximum), a more accurate idea will be given of its power than when *twenty tons* is named as the total force obtained.

Charles Umney.

Laboratory, 40, *Aldersgate Street, E.C.*

The Chippenham Case.

Sir,—I cannot think that your correspondent M. P. S. altogether deserves the indignation with which Dr. Fox has visited him.

He at all events is justified in considering a solution of eighty grains to the ounce of corrosive sublimate as at the least a very strong application to the head of a child, and his argument is scarcely unfair when he objects to it because it is both "both powerful and caustic."

Here, as it seems to me, he has touched on the real source of risk attending its use; corrosive sublimate is not only one of the most powerful in its effects on the system of the compounds of mercury, but it is also one of the most corrosive.

We know what a valuable protection our epidermis or scarf-skin is to us in preventing the contact of various poisonous substances with the underlying true skin, which is otherwise so readily capable of absorbing all kinds of noxious substances into our systems. And we may presume that when we increase the strength of a lotion of corrosive sublimate to a point at which it exercises a corrosive action on the epidermis, we not only augment the quantity of soluble poison that is brought into such close proximity to the true or absorbent skin, but we also run a risk of destroying the thin protection which is the only obstacle to its absorption.

When, moreover, we reflect that so strong an application as the one in question can scarcely ever fail to raise a blister, and consider the fair possibility of that blister getting broken, we must admit that a timid man might be excused for hesitating before he applied it.

If, then, there be any possibility, however remote, of the lotion being absorbed by the skin, it may be well to consider what is the quantity of corrosive sublimate that incurs this possibility at each ordinary application of the lotion. Eighty grains to the ounce gives ten grains to the drachm. Now, placing an average adult dose of corrosive sublimate at the sixteenth of a grain, the drachm of lotion will be found to contain one hundred and sixty adult doses. Suppose, however, that only one-fourth of that quantity (viz. fifteen drops) gets applied at a time, then we still get forty adult doses contained in a single application to the head of a child.

Now since in ringworm there are usually several patches, and some of them often attain a considerable size, I should be disposed to say that fifteen drops is a moderate rather than an excessive estimate of the quantity of lotion deposited on the skin at a single application; but if the lotion be used as Dr. Fox recommends, by both precept and example, "very freely and very frequently," then, of course, we should probably get a much larger quantity of lotion deposited on the skin, and in it, of course, a much larger quantity of corrosive sublimate.

If I may be permitted to say so, I think it is possible to have even too "keen an appreciation of the importance of the chemist not usurping the duties of the medical practitioner," and to be, if possible, too indignant at the bare idea of his "setting himself up as a judge of therapeutics as against properly qualified physicians."

It is a good thing for some of us who prescribe, that the chemist does happen now and then, in a private and friendly way, to "set himself up as a judge of therapeutics," even as against our prescriptions; and we may be glad that this leads to his sometimes making a courteous inquiry of us, as to whether some particular line in our prescription was intended? Still more may we be glad that this inquiry usually comes before the prescription is made up.

For my own part, if posology be a branch of therapeutics, and if to understand posology requires some general knowledge of the rest of the subject, I should feel a good deal less comfortable in the pursuit of my daily avocations if I thought that chemists would in no case venture to question my therapeutics.

In the case in question, we learn from the report of the inquest, published in your columns, that the prescription in question was personally shown by the prescriber to the chemist, who was directed to make it up from the printed formula given to him in a book. No blame whatever could therefore attach to the chemist in this case.

But if the prescription had reached the chemist in the ordinary way no one would think of complaining if he, on finding that the composition of the lotion was exceptionally strong, had first made inquiry as to whether it was "intended" before he proceeded to dispense it.

Many people, I feel sure, would in such case have held him to blame if he had failed to do so.

As Honorary Surgeon to the British Hospital for Diseases of the Skin I have had fair experience of ringworm, especially at the Finsbury Square Branch of the hospital, where contagious diseases of the skin are more rife than at the parent (Great Marlborough Street) branch. But the doubts I have expressed to you respecting the expediency of strong corrosive-sublimate lotions, have always prevented my employing them, and my experience of their effects is confined to the observation of cases in which they had already been employed by other persons. My experience thus derived is not, on the whole, a very encouraging one.

I was glad to read a letter of Dr. Fox, in the *Lancet*, written a fortnight after the accident, in which, after stating that he had used the lotion in question for the past thirteen years, he says, "It is true I do not use the remedy now, but that is solely because I like other things better." If his conversion comes late, let us nevertheless congratulate him on that conversion.

BALMANNO SQUIRE.

9, *Weymouth Street, Portland Place, W.*

THE MISTAKES OF PRESCRIBERS AND DISCRETION OF DISPENSERS.

Sir,—Dr. Tilbury Fox, in his letter of September 18th, indulges in some sarcastic remarks on the proper duties of a pharmaceutist. I should like to know whether Dr. Fox still continues the use of 10 grs. of sublimate to 1 drm. of sp. for ringworm, and if not, why not?

About a month since a gentleman suffering from syphilitic sore-throat brought me the following prescription to prepare:—

℞. Hyd. Perchloridi gr. ij
Acid. Hydrochlor. Dil. ♏v
Aquæ ℥j.
M. Ft. Garg. sæpe utend. M. ℥viij.

I cautioned him as to its use, and hastily said I would not use it without diluting it. He used it the full strength once, and only once, as it nearly choked him, and two hours elapsed before he breathed comfortably. Of course, according to Dr. Fox's theory, I had no business to make any remark, but, after my forty years' experience, as a chemist, I could not hold my tongue.

A week since the following prescription was brought to my shop:—

℞. Ammon. Carb. gr. xl (40)
Ferri Ammon. Cit. gr. xl (40)
Sp. Cajeputi ʒij
Sp. Menth. Pip. ℥iv (*sic*)
Infus. Calumbæ ad ℥viij.
M. Sumat cochl. ij ampla bis (*sic*).
Aug. 7, 1871.
Pil. Assafœtid.
,, Rhæi Co., ana ʒss.
Div. in pillul. [*sic*] xij. Sumat ij p. r. n. nocte.

My assistant had prepared the mixture as written. I noticed that the dose of sp. menth. pip. though excessive was not dangerous, but as it was prescribed by a physician in one of our large commercial cities, and had been dispensed by a pharmaceutist in the same city, of high standing, I thought it right to let the lady know that the dose was very large, and if she found it stronger than her former bottle of medicine had been I would alter it to what I considered a proper dose. After trying one dose she requested me to do this. I wrote to my brother pharmaceutist who had first dispensed it, from whom I received a very courteous reply, saying, "That the amount of sp. menth. pip. was so evidently an error that he only put ʒiv of the B.P. which was the quantity he supposed to be intended!" I think Dr. Tilbury Fox's sublimate lotion for ringworm and my young friend's gargle much more dangerous than the above sp. menth. pip. mixture, yet according to Dr. Fox we are to *dispense* but not *opine*.

London, October 3rd, 1871. THIRTY YEARS' M. P. S.

DRUGGISTS' PRICES.

Sir,—In reply to Mr. W. M. Betts, who has the good sense to put his name to his communication, I have no doubt that hundreds of chemists would be ready to dispense the given prescription at the price named.

Retail prices and dispensing prices will often clash, and if the pharmacist finds it *infra dig.* to make pennyworths, the shopkeeper must supply his place to the public.

In the prescription in question the two first ingredients are pennyworths, the next two being minim quantities are included in one pennyworth, and water is not charged.

I will illustrate this by another case; it is a fact, not imaginary. A customer brings a six-ounce bottle, and requests half an ounce of compound tincture of cardamoms and a quarter of an ounce of spirits of sal volatile aromatic, to be put into the bottle. For these he pays threepence, and requests the chemist to fill the bottle up with water.

A Latin prescription is then produced, consisting of the above ingredients, and the chemist is reminded that on a former occasion he had the conscience to charge sixpence for the same. JOSEPH LEAY.

Chilcompton, Bath, September 25th, 1871.

J. B.—A chemist is not liable under the Pharmacy Act 1868, for selling yellow prussiate of potash without the precautions prescribed for poisons. See No. 54, p. 31.

"*East Wind.*"—The comparison drawn by you is obvious, but it does not affect the point to which our remarks were directed.

E. H. S.—No.

J. H. Thomas.—See a case reported in Vol. I. of this series, p. 775.

J. Ashlin Thomas and *J. Barker.*—The letters have been received, but the coroner's mistake was pointed out in last week's Journal.

W. H. Beaumont.—We have received your letter, and are obliged for the information furnished.

Messrs. Arnold and Sons.—The sample bottle forwarded to the Editor has been handed to the Secretary for exhibition at the evening meeting. Any further notice should appear among the advertisements.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. W. B. Cordley, Hughes, Thomas, Agnew, Heddingham, J. F. Caunt, J. H. Wilson, F. R. B., L. S., S. P. G. L., J. H. D., J. C. K., "Senega," "Humulus," "Primus," "Ferrum."

In consequence of want of room, we are compelled to defer answers to several correspondents.

PROVINCIAL EDUCATION.

BY EDWARD SMITH, F.C.S.

It is with very great diffidence, and with some misgivings, that I venture to approach the subject of provincial education. The question is one of no little difficulty, involving a multiplicity of interests, and a great variety of circumstances; moreover, the subject is under the consideration of men who have far larger experience—practical experience—in the matter than I can lay claim to. Nevertheless, I feel emboldened to contribute my quota to the general fund of suggestions, inasmuch as up to the present time, no really practical and comprehensive scheme has, to my mind, been even foreshadowed.

It is desirable, and I think imperative, at the outset to clear the ground of many of the extraneous considerations which may be imported into the discussion by at once dividing our subject into its three natural sections,

1st. Whom ought we to educate?
2nd. Of what should our teaching consist?
3rd. By whom should this teaching be carried out?

1st. Whom ought we to educate?

The answer must be: apprentices who have passed their Preliminary examination. It cannot be considered either just or expedient that any portion of the education to be provided by pharmacists should consist of classical or mathematical subjects. We cannot undertake to relieve parents of their responsibility to provide a suitable education for their sons intended to practise pharmacy; therefore I conceive it to be a *sine quâ non* that we must have regard in our professional teaching solely to the requirements of those youths who have passed their Preliminary, relying upon this examination to test the fulfilment of the parental obligations; and thus it is very desirable in order to secure the most intelligent youths, that the stringency of the Preliminary should not be relaxed, but maintained fully up to a good standard of general education. Neither can we have regard to the education of assistants. He who has already passed the Preliminary, and served his apprenticeship, must be considered to have passed beyond the scope of subsidized education. He is, or should be, in a position to pass his Minor, and provide for his future teaching.

2nd. Of what should our teaching consist? If we take up the position just enunciated, it is clear that our teaching must consist of elementary chemistry, pharmacy and botany, so arranged as to illustrate, as much as possible, the usual everyday work of apprentices—practical groundwork, with just a sufficient tinge of theory to make the study interesting, and to excite the mind of an intelligent youth. The form and manner of doing this work must, to a great extent, be left to local associations. As a rule, they will best appreciate the conditions most favourable to any particular town.

3rd. By whom should this teaching be carried out? Primarily by local associations. The Pharmaceutical Society, by reason of its fixed London habitat, cannot possibly do very much directly, in the way of teaching apprentices, but indirectly it may be of immense service in encouraging and promoting, in many ways, the efforts of local associations; and, to some extent, the Council of the Society has, by grants of money, encouraged the provinces, but this has generally been done in a very spasmodic and indefinite way, with very little regard to the quality or quantity of work achieved by local associations. Indiscriminate grants are worse than no grants at all. The provinces have a right to expect help from the parent Society, and the Council of the Society may fairly require provincials to prove they are doing some good work before making a grant; in fact, the duty of the parent Society is obviously to "help those who help themselves;" to subsidize provincial associations strictly in ratio to the amount of work done, and thus to promote a healthy and honourable rivalry amongst them.

Having thus briefly gone over the main ground, and cleared our path, I will now proceed to tabulate the plan which seems to me best calculated to achieve the object we have in view. In the first place, I would propose that a number of centres, say twelve to twenty, of examination be instituted in different parts of the kingdom, at which annual examinations —conducted by an examiner deputed by, and at the expense of the Council of the Pharmaceutical Society—should be held.

2nd. That local associations be formally affiliated to the parent Society, on payment of a nominal annual fee.

3rd. That no candidate be eligible for examination unless he has passed his Preliminary, and subscribed for at least two consecutive years to an affiliated association. Assistants having served their apprenticeship not eligible.

4th. That the parent Society grant 40*s*. (say) to any local association for each one of its candidates considered by the examiner to be worthy of a prize, and 10*s*. (say) for every candidate honourably mentioned: the prizes to consist of suitable books, and to be given at the cost of the local association.

5th. An eligible candidate may compete at any centre of examination, but at not more than one in the same year.

The plan thus crudely sketched may require some further explanation. The centres of examination may be—London, Salisbury, Exeter and Plymouth alternately; Bristol, Birmingham, Manchester and Liverpool alternately; Lancaster, Carlisle, Glasgow, Edinburgh, Newcastle, York and Leeds alternately; Lincoln, Cambridge and Norwich.

The number of centres may be increased, decreased, or varied at pleasure. By holding examinations at these centres annually, the associations in the smaller as well as in the larger towns would be brought into more immediate contact with the parent Society, and every apprentice—even those in small towns without any local associations, and therefore now practically isolated—would have his interest sufficiently aroused by the chance of a prize, as to induce him to join some association, more particularly if the latter could arrange for the ready circulation of volumes from their library, and offer some little advantage to country apprentices residing beyond the limits of ready access to the local classes (say) in a moderate reduction in the regular subscription.

It must be understood that the character of the proposed local examinations would be elementary and practical, such as an intelligent apprentice might fairly hope to master, and otherwise not to interfere with the usual Minor and Major examinations at

Bloomsbury Square, but rather form a sort of stepping-stone to these examinations.

Of course, local associations would admit to their classes apprentices who had not passed their Preliminary, as well as assistants, or any others, but these could not go in for examination so as to count for any grant from the parent Society.

The moral effect of these provincial examinations by a London professor, sent directly by the Pharmaceutical Society would be immense, but need not be dilated upon here.

The object in having provincial associations affiliated to the parent Society is to bind, as completely as may be, the whole of the country into one common bond of union, to make the Pharmaceutical Society what it really ought to be, the point around which all provincial associations should rally. There cannot and must not be any diversity of interests between London and provincial associations.

With regard to the requirement that candidates should have subscribed two years before being eligible for examination, this is intended as a source of support to local efforts; for, without this, a youth might subscribe just for one session and carry off the prize. It would not be well that this should be possible. By this rule a youth would, by way of subscription, help to keep up the funds of his association. Local monetary effort must always, to a great extent, be depended upon, and should, therefore, be encouraged in every legitimate way.

It may be asked, whence can come the funds to subsidize local associations? Can the Pharmaceutical Society undertake the task? I think it can. The Society is growing in wealth and power, and ought to expend some of its surplus moneys in the cause of elementary education. If we examine the balance sheet of the Society as put before the last May meeting, we find that the two professors of chemistry and pharmacy and botany and materia medica together received £600 for their lectures, whilst the fees from pupils amounted to just over £200, thus, apparently, involving a loss of nearly £400 per annum to the Society. I have nothing but unqualified praise to bestow upon these learned gentlemen in regard to their efforts; but how can they "make bricks without straw"? As I have previously said, Bloomsbury Square is not, and cannot be ubiquitous. If then these gentlemen were to curtail their lectures at Bloomsbury, and for one month in the year go on a round of examination, their efforts, I firmly believe, would be rewarded with triumphant success; and if they were to deliver a lecture or two at each centre on some interesting pharmaceutical subject, the result would be of incalculable benefit, and most inspiriting to local organizations.

I might expand this paper almost indefinitely, the subject is well worth it; but at present my object is solely to state the case sufficiently to make it intelligible.

I am not sanguine enough to think that so important and intricate a subject will be settled offhand and without much controversial discussion; still I hope and believe there is here shadowed forth a plan, which, although at present but crudely developed, has in it the elements of a sound, practical and comprehensive system of provincial education; and with this confession of my faith, I leave it in the hands of your readers.

CERTAIN PROPERTIES OF THE TUTU PLANT (CORIARIA RUSCIFOLIA).*

BY H. G. HUGHES, M.P.S., HOKITIKA.

(*Concluded from page 282.*)

Respecting the efficacy of a mixture of lime and water in cases of poisoning, before giving the report by Dr. G. H. Acheson, of this town, it may be as well to state that the antidote only was given; nothing was administered by way of general treatment besides what results when a mixture of cream of lime with water is added to the simple extract of tutu rendered fluid with a little water. The extract was prepared by macerating the young, but woody and developed, shoots in water, acidulated with acetic acid, and applying a gentle heat, pressing and evaporating to the consistency of an extract. These shoots yield extract more poisonous than the succulent ones. The handling of these wet shoots rather frequently induced vomiting. The day the extract was prepared, its mixture with lime gave strong ammoniacal vapour. It was very poisonous. About half a scruple was given to a cat; I was obliged to leave her, and on my return, in twenty minutes' time, found her dead.

On the second day the reactions were similar.

On the third day after preparation, the ammoniacal vapour was just perceptible, but readily detected by fumes of hydrochloric acid; it was but slightly poisonous.

On the fourth day the extract had become much thinner, gave no ammoniacal vapour, and was not in the least poisonous.

The extract preserved its original consistency until the third day, when it became soft, which condition was much increased by the fourth day. During this time the weather was fine; I do not think the atmosphere was more humid than usual. Three extracts prepared at intervals of five or six days, and in succession, behaved in a similar manner.

When the cream of lime is added to good (poisonous) extract, it coagulates or thickens, and appears to swell immediately, strong ammoniacal vapour being at the same time evolved. Should the extract possess fragrancy, owing to some of the fragrant oil not being dispelled during the process of preparation, it is at once destroyed by the lime. It is important to observe that the inert extract on the fourth day after preparation retained this odour. From what I have seen of its action, it possesses emetic properties only.

Recapitulation.—Acetic acid fixes or preserves the poisonous property (for a time at least), arresting its decomposition. When lime is added to good extract (poisonous), strong ammoniacal vapour is evolved; but on the fourth day, in the lime mixed with it, although possessing the odour of the essential oil, not the slightest trace of ammonia can be detected; the oil also, when destroyed by the lime, not giving any ammoniacal vapour, indicates it to be of a different composition, and a non-nitrogenous oil. The decomposition of the poisonous principle, resulting in the evolution of ammonia, shows nitrogen to be present in it. The fragrant oil comes over at 212° F., the poisonous principle at between 350° and 400° F. The spontaneous decomposition of the extract was carefully watched; there was no

* Read before the Wellington Philosophical Society, and reprinted from the 'Transactions of the New Zealand Institute,' vol. iii.

other perceptible change than its assuming a more fluid condition.

From what has been stated, it is observable that the poisonous principle is very unstable when in a state of extract, decomposes immediately when neutralized with lime, and is fixed (for a time at least) by acetic acid.

When the treatment of the plants was prolonged, the results were variable and of an indifferent character, which I attributed to the principles decomposing spontaneously when in the presence of water. Also, as the season advanced the results were less satisfactory, as if indicating a smaller amount of the various principles,—that is, with reference to the shoots, bark, and leaves.

The young ground shoots (plants growing from the ground) gathered in March, 1869, yielded most of the supposed alkaloid and the other principles. They were, besides, more woody than those subsequently examined. The last examined were collected on the 3rd of December, 1869, and were shoots of the tree, but no trace of alkaloid was found, perhaps owing to the above-mentioned supposition. They were macerated for at least twenty-four hours in distilled water, with the application of a gentle heat.

Report of Experiments made by Dr. Acheson, with a Mixture of Slacked Lime and Water as the Antidote for Tutu Poison.

"For some time past I have been experimenting on various animals with a watery extract of tutu, prepared by Mr. Hughes, pharmaceutical chemist of this town, and, at his request, I now state the result.

"I administered to a cat fifteen grains of the extract; twenty minutes after, the respiration became very frequent, slight twitching of extremities, and in five minutes more a severe attack of convulsions, which lasted about three minutes. Then, an interruption of ten minutes, followed again by a severe paroxysm, which lasted four minutes; again intermission of ten minutes, which was followed by a severe paroxysm of pure tetanic spasm, in which she expired. In this case, from the commencement of symptoms of poisoning, the slightest noise would invariably excite a recurrence of the paroxysm.

"2nd. I administered to a large dog half a drachm of the extract. Fifteen minutes after, breathing hurried, fæces expelled, vomited several times so severely that I was perfectly persuaded that the poison had been expelled. At the expiration of thirty minutes, tremors and slight twitching of the muscles of the extremities, and very much afraid to move out of one position. Then a severe paroxysm of convulsions, gnashing of teeth and frothing at the mouth, the paroxysm lasting about four minutes, then a remission of ten or twelve minutes, which was followed by the most severe and final paroxysm.

"In the above two cases, the extract had been prepared but two days.

"3rd. On the afternoon of the third day after the preparation of the extract, I administered the same quantity to a similarly sized dog. At the expiration of thirty minutes, it having produced no effect, repeated the dose in a *fluid* state. The double dose merely produced sickness and slight tremor.

"On the fourth day the extract had become very thin and watery, which led me to suppose that spontaneous decomposition had destroyed its poisonous property. I therefore increased the dose to two drachms, yet no symptom of poisoning.

"A few days after the above-mentioned experiments were made, I, with the assistance of Mr. Hughes, administered about a drachm of fresh extract to two dogs. To one of the dogs the extract was given in a mixture of lime and water. It remained in the stomach for several minutes before vomiting commenced. After the expiration of half an hour from the cessation of vomiting, we determined to administer a drachm of the extract alone, being merely dissolved in a little water. This he retained for twenty minutes without any vomiting taking place. We then administered to him a quantity of lime mixture. He never showed the slightest symptom of poisoning. To the other dog the extract was given in a quantity of water merely. A few minutes after administration, symptoms of poisoning commenced, and in twenty minutes he had a regular attack of pure tetanic convulsions. Immediately after the first paroxysm, we emptied into the stomach a quantity of the lime mixture, after which he had one severe fit, from which he recovered rapidly, and in the course of a very short period he was perfectly free from all symptoms of poisoning.

"We administered to a rabbit about thirty grains in the solution of lime, it never evinced the slightest symptom of poisoning.*

"In every case in which we administered the lime mixture the animal recovered rapidly, and when the extract was active it invariably gave fumes of ammonia on being mixed with lime.

"From what I have seen I am perfectly persuaded that lime is an antidote against the tutu poison; also, that by the fourth day of the watery extract it is almost inert.

"In every case experimented upon the animal remained perfectly conscious; indeed, the mode of attack and the appearance of the animal while in a paroxysm, strongly resembles poisoning by strychnia.

"G. H. Acheson, F.F.P.G.

"*Hokitika, April 5th*, 1870."

TUTU AS A DYE-WOOD.

Some woollen material, silk and linen, were boiled for a short time (half an hour to an hour), with some chips (the wood of the tree), afterwards treated with a hot solution of copperas. The colours were pure, from a neutral grey to a deep black, the dye varying in intensity according to the number of times the material was treated with the decoction of the wood. The dye is superior to that of logwood, inasmuch as it is pure. Woollen materials take it readily and well, silk is not so readily affected, and linen takes more time. The wood of the tree may be used as a substitute for logwood, and this property of the wood of the tree may be studied to advantage and profit.

[The results given in the above paper being somewhat at variance with those obtained by Mr. Skey (*loc. cit.*), they have been carefully re-examined in the laboratory, and Mr. Skey is of opinion that some of the reactions cited by Mr. Hughes are not satisfactory, for the following reasons:—

* Tutu does not act as a poison upon rabbits. I kept two of them for two days feeding upon tutu leaves, and afterwards gave them several large doses of the poisonous extract. I thought one of them appeared a little stupefied, but it would eat well enough notwithstanding.

1st. That the oil under examination must have been saponified by the processes employed.

2nd. That the temperature used was such as must have produced many bye products by destructive distillation, and, among others, acetate of ammonia, the presence of which would sufficiently account for the reactions Mr. Hughes attributes to the presence of an alkaloid.

3rd. That the action of lime, as an antidote, is not due to its decomposing an alkaloid, but to its forming an insoluble soap with the poisonous oil; and Mr. Skey still adheres to his opinion, that dilute acids should be administered in cases of poisoning by tutu.

4th. That the dyeing properties of the juice of the tutu plant are due solely to the abundance of tannin they contain, and are not analogous to the special dye principle of logwood (hæmatoxyline), for which reason he does not think that it can be used for dyeing any shade to which tan bark is not equally applicable.

Mr. Skey's views are explained in a paper, which must be deferred for future publication.—Ed. Trans. N. Zeal. Inst.]

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Plumbi Oxidum, PbO.—Out of the several existing compounds of lead and oxygen, this is the only one which exhibits a well-marked basic character; that is, which readily neutralizes acids, producing water and crystallizable salts as the result of the reaction.

Litharge, the ordinary form of plumbic oxide, is prepared by exposing melted lead to the oxidizing action of a current of air at a temperature at which the oxide melts.

[§ In heavy scales of a pale brick-red colour, completely soluble without effervescence in diluted nitric and acetic acids.] It rarely contains more than traces of impurities, chiefly the oxides of other metals, and a small quantity of red-lead, to which the colour is chiefly due. Plumbic oxide is slightly soluble in water, and is in any form strongly alkaline to test paper, and absorbs carbonic acid gas from the air. (See Liq. Plumbi Subacet.) It is easily fusible, and in that state rapidly dissolves silica: a mixture of lead-silicates constitutes flint-glass. The remaining oxides of lead are—1, an imperfectly known suboxide, Pb_2O; 2, brown plumbic peroxide, PbO_2, left when red-lead is treated with nitric acid; 3, red-lead or minium, which is a compound of plumbic oxide and peroxide, usually having the formula, $2PbO, PbO_2$ or Pb_3O_4.

Potassa Caustica.—[§ Hydrate of potash containing some impurities.]—Obtained by boiling down liquor potassæ in an iron dish. It is liable to the same contaminations as the solution from which it is made. Being very deliquescent, it must be kept in well-closed bottles.

Potassa Sulphurata.—This compound is prepared by melting together carbonate of potassium and sulphur, continuing a moderate heat until effervescence is over.

$$3K_2CO_3 + 4S_2 = \underset{\text{Hyposulphite.}}{K_2S_2O_3} + \underset{\text{Sulphide.}}{2K_2S_3} + 3CO_2.$$

[Watts, Pharm. Journ. Nov. 19, 1870.]

[§ Solid greenish fragments, liver-brown when recently broken. About three-fourths of its weight are dissolved by rectified spirit.]

The Pharmacopœia orders rather a larger proportion of carbonate of potassium than is required to satisfy the equation given above. The hyposulphite of potassium, when heated too strongly, decomposes into sulphate and pentasulphide.

$$4K_2S_2O_3 = 3K_2SO_4 + K_2S_5.$$

In addition to the two main constituents, hyposulphite and trisulphide, there may, therefore, be present carbonate, sulphite and pentasulphide of potassium.

This compound is decomposed by hydrochloric acid with evolution of sulphuretted hydrogen and deposition of sulphur.

Potassæ Acetas, $KC_2H_3O_2$. Carbonate of potassium is dissolved in a slight excess of acetic acid, and the solution having been evaporated to dryness, the salt is melted by the very cautious application of heat. The solution must be distinctly acid, and the salt barely fused, with least possible exposure to air, or the product will not be white.

[§ White foliaceous satiny masses very deliquescent, with a watery solution of which tartaric acid causes a crystalline precipitate ($KHC_4H_4O_6$), sulphuric acid the disengagement of acetic acid, and a dilute solution of perchloride of iron strikes a deep red colour (ferric acetate, $Fe_2 6 CuH_3O_2$). Neutral to test paper, entirely soluble in rectified spirit.]

CINCHONA CULTIVATION IN BENGAL.

The following Report from C. B. Clarke, Esq., M.A., Officiating Superintendent, Botanical Gardens, and in charge of Cinchona Cultivation in Bengal, to the Secretary to the Government of Bengal—(No. 269, dated Botanical Gardens, Calcutta, the 26th April, 1871),—has been received:—

Sir,—I beg leave to submit the annual report of the cinchona plantations near Darjeeling for the year ended 31st March, 1871, in which is included also the half-yearly report for the six months ended 31st March, 1871.

The cinchona plantations have lost, by early death, Dr. T. Anderson, who introduced the cultivation into Bengal, and under whose superintendence the present successful growing of cinchona has been brought about. In the opinion of his medical advisers, the unsparing zeal with which Dr. T. Anderson exposed himself personally in the steaming valleys of Sikkim cost him his life.

Dr. T. Anderson commenced the propagation of cinchona plants in Sikkim in 1862, but for several years little progress was made. Sinchul, Lebong, Upper Rungbee, and Rungyroong, were localities successively tried and found successively not well suited to the culture. The young stock was very unhealthy, and Mr. Mann informs me he then had to throw away young plants by thousands. Dr. T. Anderson also received, privately, the opinion of a very high authority, that cinchona could never be profitably grown in Sikkim.

Dr. T. Anderson, undaunted by these discouragements, and by the still more disheartening doubts which some of his best gardeners felt, applied himself steadily to the overcoming, one by one, of the difficulties experienced. And by 1867-68 these difficulties had been so far overcome, that he felt no doubt of economic success in the growth of *C. succirubra* and *C. calisaya*. When Dr. T. Anderson left for England in the spring of 1869, he left his successors merely to pursue in cinchona culture the plans of proceeding which he had brought into successful operation.

An official report is hardly the proper place to enlarge on the private loss sustained by the death of one who died deeply regretted by every one who knew him, but I may express here my opinion of the magnitude of the loss which science and this country have sustained by the death in early prime of a botanist, who simply said, that after nine years' continued study of Indian plants, he felt that he might now begin to publish with satisfaction to himself.

The year has been unusually wet, the rainfall being about 40 inches in excess of the average amount. The cold-weather six months, ended 31st March, 1871, have also been unusually moist, and growth, shown by the measured plants during the cold weather, is unusually large in consequence.

No improvement in the plantations of *C. officinalis* took place during the year: the number of plants returned in the table appended is but 440,000, which must be understood to mean that no fresh plants have been planted out since the last report, and that the number of deaths has not been counted. In accordance with the recommendation in paragraph 2 of the report of the cinchona commission, the *C. officinalis* is now being cut down. There is every reason to suppose that Dr. T. Anderson was right in attributing the failure of *C. officinalis* at Rungbee to the too great moisture, for on the drier slopes of Tukvar, north of Darjeeling, the president of the cinchona commission found a small experimental plantation of *C. officinalis* much superior to any part of the Rungbee plantations, and showing promise of making at least small trees.

The number of cinchona plants in permanent plantations was as under:—

	C. succirubra.	*C. officinalis.*	*C. calisaya.*
31st March, 1870 . .	1,055,100	406,899	4,000
30th September, 1870	1,219,715	440,000	24,860
31st March, 1871 . .	1,233,715	440,000	33,000
Total . .	14,000		8,140

Of *C. succirubra* there are also now 480,000 young plants (mainly seedlings) in the nursery beds. I may explain once more that the nature of the ground at Rungbee does not admit uniform planting. Where the ground admits, the plants are planted 6 feet by 6, and when 1200 have been put out, this is reckoned an acre of cinchona, a further allowance of 20 per cent. being made for filling up of vacancies. The vacancies are filled up once only, in the year succeeding that of planting.

In accordance with instructions received from the supreme Government, it was attempted to raise 500,000 plants in the nursery beds for planting out during the present season, and the jungle has been burnt on sufficient land to hold the 480,000 that have been raised. It has been observed, however, that as in the case of most other trees, the chief point to secure in planting out young cinchonas is that they shall start well; hence those parts of the plantations planted early in the season are found generally very superior to the autumn planted portions. It is therefore proposed to plant out as many of the 480,000 young succirubras as can be got out before the end of July, and to reserve the rest in the nursery beds for planting out in the early spring of 1872.

The *C. calisaya* is planted now at the same distance apart as *C. succirubra*, viz., 6 feet by 6; the early planting was 5 feet by 5, which was certainly too close. The number of "acres," therefore, of *C. calisaya* will be about thirty in permanent plantation; and this will be increased to about eighty during the present season.

The harvest of *C. calisaya* seed is good, and will suffice for a large extension of *C. calisaya* by seedlings next year.

I have to thank Herr Von Gorkom, director of the Government cinchona plantations of Java, for several valuable consignments of seed of *C. calisaya*, of which nearly every single seed germinated.

The plantation has been able to respond to all applications for seed of *C. succirubra* and of *C. officinalis*, but is likely for another year to have less *C. calisaya* seed than is wanted for its own requirements.

The general growth of the plantations of *C. succirubra* and of *C. calisaya* has been good during the year, and their present condition satisfactory. The number of deaths, except of plants during their first season out, which have been planted in swampy places, has been exceedingly small. Cinchonas planted where the water stagnates never grow at all, as Mr. McIvor has observed; and some members of the cinchona commission have suggested that a little more selection in regard to site of plantation might be advantageously employed. The ground for planting is cleared of jungle by burning, and it is very difficult to foresee that cinchona will not grow in any particular spot: for, however wet it may be, provided the water does not hang, cinchona may grow excellently; and on the whole the head gardener inclines to uniform planting, and filling up vacancies but once, as has been for some time the practice.

The important portion of the plantation is now Rishap, and I have prepared the subjoined table to show the growth of the measured plants there of the two species *C. succirubra* and *C. calisaya*:—

RISHAP.—*Altitude*, 2000 *feet*. *Planted* 29*th March*, 1867.

	Height in inches on 1st April, 1870.	Height in inches on 1st October, 1870.	Height in inches on 1st April, 1871.	Growth for six months ending 1st April, 1871.	Growth for twelve months ending 1st April, 1871.

			Total . .		425

This gives an average growth per succirubra-tree of 45·8 inches, and per calisaya-tree of 42·5 inches, during their fourth year out. Mr. M'Ivor describes the growth of the *C. calisaya* at Rishap as splendid during the first two years, and in some cases during the first three years. But I submit that these figures fully justify the unanimous statement of the gardeners at Rungbee, that the rate of growth during the first two or three years is subsequently maintained, or nearly so.

There is a numbered stick at the base of each measured tree, and as the height and continued growth of these trees is a fact which cannot be got over, I shall mention that they were measured by Mr. Kennedy, the gardener at Rishap; that the measurements have been verified by the head gardener in charge; and that, further, I measured these trees myself early in March, and am therefore able to state that the measurements sent down cannot possibly be materially in error.

But it has been asserted to me that the sticks at the base of the measured trees have been shifted. If this were so, it would deprive the measurements of all value, unless as to the "exceptional" growth of trees at Rishap, which is not a disputed fact.

I must, however, be permitted to show in detail that the sticks cannot (except in one instance, viz. *C. calisaya*, No. 2) have been shifted since the plants were put out.

First, I can state of my own knowledge that sticks have not been shifted since August, 1869, when I first saw the plantation; and secondly, the gardeners on the plantation state positively that no stick has been shifted since Mr. Kennedy (the gardener now in charge at Rishap) came there, upwards of three years ago.

The circumstantial evidence that these sticks (except *C. calisaya*, No. 2) have never been shifted, is exceedingly strong.

First, as to the ten *C. succirubra* sticks. The first eight sticks are placed regularly against one row of plants near the gardener's bungalow, and the sticks Nos. 9 and 10 are placed opposite two plants in the next adjoining row. It is tolerably clear that the gardener placed the sticks against a good row of plants near his bungalow, convenient for close observation. He selected as good a row as he could find close to the bungalow, but he might have selected a far better row if he troubled to go a few yards down the hill. As to sticks Nos. 9 and 10, they were placed in the next adjoining row, and certainly not against the two best trees. Indeed, No. 10 is about the worst tree in the row, and has (Mr. Kennedy says) always been so; and it was probably selected because it was the tree next the path and easy to get at to measure.

The trees being in rows, no one of the first eight sticks could have been shifted unless all were, which is clearly impossible; and as to sticks Nos. 9 and 10, assuming that they have been shifted, they must have been shifted disadvantageously to the measurement.

There remains in addition to these arguments Mr. Kennedy's very plain remark, that if he was to shift the sticks to one of the best rows of trees, he could show a very different admeasurement, as several trees in four years out have passed twenty-five feet, and very many have passed twenty feet.

Next we come to the ten *C. calisaya* plants. In this case one row of eight trees is taken, in which the sticks proceed regularly from one to eight, and sticks No. 9 and 10 are placed regularly in the next row. But the stick No 2 has been evidently removed at some time from the second tree, and now stands at the base of the eleventh tree.

A very slight examination of the second tree shows that early in life it lost its leader, which was doubtless the reason that the stick was shifted; but the tree No. 2 is now about as large as the others. The stick No. 2 was doubtless shifted very shortly after the plants were put out, and if it were put back to plant No. 2, the growth of the *C. calisaya* would stand as nearly as possible the same. The biggest *C. calisaya* trees are in an adjoining row to the measured row.

I should add that these measurements show less than the fair growth of the trees, because in order to avoid all cavil about shifting the sticks, or about cutting out the bad trees and leaving only the successful ones to be measured, the lines of the measured trees have not been thinned, so that the trees stand too thickly to show what the growth is in the plantation after thinning out. The growth in the small patch of plantation thinned out in the cold weather, 1869–70, is certainly greater than that shown by the measured trees.

The average growth of the measured plants is a fair index of what the cinchona trees are doing at the level 2000 feet, and below it; but the growth is steadily less as we ascend the hill, and in several parts of Rishap, at 3500 feet, is comparatively very small. A considerable portion of the 1868 and 1869 plantations, was planted at these higher levels, and will come into bark-bearing much later than the lower level trees. A large area of 1868 planting will not be fit for thinning before Christmas 1872–73, and this will so far diminish the amount of bark which I calculated on from next season's thinning. On the other hand, the Teesta plantations, which were so seriously damaged by fire and deer that they were reported, in June 1869, no longer worth report, have recovered wonderfully, and now exhibit patches which some members of the cinchona commission thought the finest in the whole Rungbee plantation. These trees are growing at an elevation of from 450 to 900 feet above the sea, and are covered with lichens. The policy at Rungbee has been for some time to push the *C. succirubra* high up, and reserve the low level ground for *C. calisaya;* but I do not now feel at all sure that this will not have to be altered, and that the low level ground lately handed over to the forest department may not hereafter be asked for again for cinchona. The ground is, however, much less saturated by springs and swamps at the upper levels, and though the growth is slower, the plantation stands more uniformly, less in patches, there than below.

With the continued growth of the older trees (*i.e.* those which have entered at least on their fourth year of growth out in the plantation). I feel no apprehension whatever that they may early die out; and as regards the opinion that 100,000 of such trees will die out within the current year, I do not think it necessary to lengthen this report by a particular attempt to refute it by argument, the time being so very short, and, if such a calamity be impending, any means of obviating it so impossible. Should it occur, it will be a most startling surprise both to myself and every gardener about the place.

A plant appeared sporadically among the *C. succirubra* plantations raised from Ceylon seed, which early attracted the attention of Dr. T. Anderson. In its powerful habit of growth and general appearance it much resembled *C. succirubra*, but yet clearly was not exactly that species. It was supposed to be a hybrid, and became known at Rungbee as *the* hybrid, to distinguish it from the various other casual hybrids. As the plants of it grew bigger, the head gardener was able to satisfy himself that it was no hybrid. Last year, at Dr. T. Anderson's suggestion, the bark of one tree, two years old, was sent home for analysis to Mr. Howard, whose report was most favourable; the quantities of total alkaloids and of crystallizable quinine being both rather higher than in our *C. calisaya* of the same age. As far as can be judged from the dozen specimens of this plant about the plantation, it seems a hardier plant even than *C. succirubra*, and to flourish both higher up and lower down than *C. succirubra* will. I accordingly instructed the head gardener in charge to get up some stock of it, and there are now 1000 stock plants of this species, so that it will be possible to propagate it and extend its cultivation very rapidly.

I received, about Christmas, two cases of *Cinchona pitayensis*, which were sent out by the Secretary of State from England in charge of Dr. Simpson, now civil surgeon of Patna, and which arrived in good condition. It is very difficult to judge of the species of cinchona while young; but this, nevertheless, carried such marked characters, that the head gardener became at once convinced that our unknown so-called hybrid was no other than *Cinchona pitayensis*.

When Mr. M'Ivor, however, arrived at the Rungbee plantations in February last, he at once recognized our hybrid as *C. uritasinga*, with which the analysis of the bark well agrees; but shortly after arrived Mr. Broughton, who doubted very much whether the plant could be *C. uritasinga*.

In the absence of flowers and fruit, no botanical determination can be attempted, and the similarity of the leaves of different species of young plants, as above stated, is so close, that the identification of this "hybrid" must still remain a problem to be solved. It is, however, doubtless destined to prove one of the most valuable species at Rungbee.

During the cold weather 1870–71 about 12,500 lb. of dry succirubra bark have been obtained from the thinning of the plantations. Of this, 5000 lb. of the thickest bark have been sent for sale in the London market, and the remaining 7500 lb. have been boiled at Rungbee. Owing to the imperfect working of the screw-press used in the manufacture, more bark could not have been cut unless we had been prepared to sacrifice all the thinner bark, which (being worth only about sixpence per pound) would scarcely pay for transit to England. To take three trees out of four (as was originally proposed), would have given us about 300 lb. of bark per 1200 trees, which was the estimate I formerly put forward. As, however, our means of working the bark were limited, only every alternate rank of trees was thinned out, and a considerable area of the 1867 planting was not touched at all. I am not sure that this curtailment of the thinning will be any loss ultimately. In this estimate of 300 lb. per acre of thinnings at the end of the fourth season out, it must be observed, however, that only 150 lb. of the best is worth 1*s*. 9*d*. per pound in London, the remainder is barely worth working up on the spot. The alteration proposed by the cinchona commission is that next year a portion of the prime bark should be worked up with the thinner bark at Rungbee, in order to give the process of manufacture a fair chance of proving remunerative.

After visiting the manufactory of cinchona bark at the Government Nilghiri plantations, by the orders of the Bengal Government in April, 1870, I came to the opinion that Mr. Broughton's method of preparing the alkaloids from red bark was an excellent one, and I was authorized by Government to introduce this process of manufacture experimentally at Rungbee. A sum of Rs. 11,250, for the expense of machinery, was placed at my disposal for the year ended 31st March, 1871.

The machinery which I have got under this sanction consists mainly of the following items:—

	Rs.	As.	P.
Boilers, cones, and presses made at the Government dockyard, and charged for merely by a book credit there. Grand total expended up to 31st March, 1871	5111	0	0
Further expenditure estimated requisite to complete the machinery now in hand	400	0	0
A Coffey fractional still, with rectifier, cost (in England)	1043	7	6
Scales and a hot filter, obtained from Messrs. T. E. Thomson and Co. . .	154	10	6
Carriage of machinery, and smaller expenses	490	9	6
Total Rs. . .	7199	11	6

I am glad to believe that the whole of this machinery (except the hot filter) is well adapted for the manufacture in question.

The only serious difficulty in carrying out the work of manufacture has been with the press. A large part of the expenditure at the dockyard, viz. about Rs. 2000, has been laid out on a hydraulic press, now ready for dispatch to Rungbee. The engineer at the dockyard has taken great pains with this press, which was seen in an advanced state by Mr. Broughton, and I am sanguine that it will answer the expectations formed of it.

The outlay on house accommodation for the manufactory has been very small, as bamboo sheds are inexpensively raised by the hill men. In the distilling-house there is much alcohol and many large fires, and I have lately replaced this shed by a brick building.

The stripping of bark can only be carried on advantageously in the autumn and spring, as during the rains the bark produces a much smaller percentage of alkaloid. During the working season, now nearly past, about 7500 lb. (dry) of the twig bark has been boiled down, and the first (lime) precipitate formed therefrom. The first sample of alkaloid sent down from Rungbee, made by the two gardeners (Messrs. Gammie and Biermann) and myself, was tried experimentally in the Calcutta hospitals, and found by Drs. Brougham and Macnamara excellent, and apparently of equal therapeutic value with the commercial sulphate of quinine. The second sample, of alkaloid manufactured at Rungbee was also found by analysis to be good. The third sample sent down to the medical store-keeper, Calcutta, has been discovered to contain 10·5 per cent. of metallic copper, and the cinchona commission recommended that the two gardeners in charge should cease working, and the distillation process has been accordingly stopped for the present. It was not understood to be possible that copper could appear in the resulting alkaloid, except in minute quantity; and even now that this serious accident has occurred, Mr. Broughton states (in the cinchona commission proceedings) that he can hardly conceive how it did occur.

I wish merely to remark here that, in my opinion, the occurrence of this accident has nothing whatever to do with the merits of Mr. Broughton's process. That process is the only one before us for obtaining the alkaloid economically from red bark, except the suggestion of steeping the bark cold; and I think it extremely improbable that the latter plan will eventually prove successful, since Mr. Broughton has discarded it after giving it what he considers a satisfactory trial.

The cost of working 1000 lb. of wet bark by Mr. Broughton's process at Rungbee has been reduced to Rs. 25, exclusive of cost of European superintendence. Great credit is due to Messrs. Gammie and Biermann for their ingenuity and perseverance in bringing the cost down so low. Mr. Gammie is particularly successful in executive work in any department to which he puts his hand, and Mr. Biermann is a man of superior education, as well as naturally clear-headed. It is considered by the cinchona commission that if the expense of carrying out Mr. Broughton's process of manufacture proves no greater than it has in their hands, no other process can possibly compete with it at Rungbee; and the cinchona commission have accordingly recommended that this process of manufacture be employed next season. It is perhaps hardly necessary to explain that, in conducting the work so as to give no copper in the result, a rather less cost is incurred.

The lime precipitate may be kept uninjured any length of time, and nearly the whole precipitate from the season's working remains thus now stored at Rungbee. Also none of the proceeds of sale of bark have yet been actually received, partly owing to the death of Dr. T. Anderson, to whose agents the earlier small consignments took place. I did not budget for any receipts from the plantation for the year ended 31st March, 1871, but I estimate that nearly Rs. 8000 worth of bark had been dispatched from the plantation by that date.

The cinchona budget grant for the year ended 31st March, 1871, was Rs. 64,741. The total amount drawn was Rs. 53,746-2-1, exclusive of the book credit of Rs. 5111 for machinery. Subtracting from this Rs. 53,746-2-1, the sums also actually paid out for machinery, there remains Rs. 51,631-15-2 as the actual current expenditure at Rungbee for the year. There is included in this the cost of the manufacture, in buildings, superintendence, labour, wood, charcoal, etc., and also the cost of cutting and stripping bark, drying, packing and dispatching it. There is also included a very considerable miscellaneous expenditure, as on fibrous plants, in collecting seeds, orchids and ferns, and packing and dispatching them. All these calls on the cinchona plantation, though apparently trifling where labour is cheap, really cost a good deal, as they require the supervision of a European gardener. These considerations must not be overlooked, or the cost of the Government plantations may appear too high as compared with that of private planting.

The plantation of the Darjeeling Cinchona Association at Pomong, which adjoins the Government Rungbee plantations, has been considerably extending its operations, and by the end of this spring there may be 1000 acres of *C. succirubra* on the Pomong plantation. The course taken by the directors of Pomong lends a strong support to the belief that cinchona will prove economically successful in Sikkim within a very limited time.

DISINFECTION.*

No. II.

In practising disinfection it has been sought either directly to influence the state of the atmosphere surrounding us, or else to operate upon the solids and liquids with which we come into relation more or less closely in the course of daily life; and, if we would have definite ideas on the subject, the distinction between these two methods of operation must be kept clearly in view.

The *direct* disinfection of the general atmosphere of a town is a task too hopeless to be undertaken by man; as will be manifest from the mere consideration of the vastness of the mass of air to be dealt with, and the comparative minuteness of the materials wherewith to deal with it. Not by one-tenth per cent. can all the breathing of all the inhabitants of a town, and the burning of all the fires in it, alter either the percentage of carbonic acid, or of oxygen in the general atmosphere pervading the town. If, then, our means of influencing the atmosphere are so limited that we cannot add to it so much as the one-tenth per cent. of any material, what chance should we have—even if we were to expend the entire national revenue on the undertaking—of so thoroughly dealing with the mass of the atmosphere pervading a town as to eliminate any impurity?

In the days of the cattle plague, those who were set in authority over us made an assault of this description on the atmosphere of the country. They swept the air of the fields with towels dipped in carbolic acid, and borne aloft on the horns of the cattle, hoping thereby to rid the air of cattle-plague germs. As well might they have tried to alter the composition of the water of the Irish Sea. The first step in practical disinfection is the comprehension of the fact that, whether it be poisons or germs we fear in the out-door atmosphere, we cannot remove them from it by the employment of anything either to decompose them or to kill them.

Leaving the streets and entering the houses, one thing at least is possible, and that is, to ventilate and secure that the air within the house is not much worse than the air outside. Obviously, too, the limited air of a room lies within the compass of the action of such quantities of chemicals as we are able to command. But whether it is economical to attempt the purification of the air of a room by acting upon it by chemicals, or whether the means which are in vogue are effectual, are other questions. The last we will now take up.

We have before us an excellent little card (excellent we say in the sense that it affords a graphic representation of the more useful expedients) bearing on it the inscription "Disinfectants and how to use them," by Edward T. Wilson, M.B., F.R.C.P.; and among other directions are the following:—

"*For an Unoccupied Room.*—Pour two wineglassfuls of dilute sulphuric acid (oil of vitriol) over two ounces of chloride of lime in an earthenware saucer, placed high near the window. It bleaches and is apt to make whitelimed walls sweat. Useful for cabs.

"*For an Occupied Room.*—Put a crystal or two of chlorate of potash into a saucer of muriatic acid (spirit of salt) placed high, as the gas is heavier than air."

We presume that the rooms are of ordinary dimensions; say 14 feet square and 10 feet high, and for convenience of calculation let us take the contents of a room 4 metres square and 3 metres high. This gives 48 cubic metres, or 48,000 litres capacity. Now from the 2 ounces of bleaching powder we should do well if we got 5 litres of chlorine gas. We have, therefore 5 volumes of chlorine in 48,000 volumes of air, or about 1 volume of chlorine in 10,000 volumes of air; or, in percentage, 0·01. This is for the *unoccupied* room, but for the *occupied* room the proportion of chlorine (from the crystal or two) would be very small indeed.* Chlorine so highly diluted is not the energetic reagent that it is when pure. If there were traces of sulphuretted hydrogen in the atmosphere of the room, they would co-exist for a long time with so weak a gaseous mixture of chlorine, and germs would probably be untouched by it. In short, such a chlorinous atmosphere, though dreadfully disagreeable to human inhabitants, might be organically impure.

The card from which we have quoted falls foul of scents. "Scents are useless," says the card, after having recommended how we may make the sick-room stinking under pretext of purifying its atmosphere. Wiser far were it to make it fragrant with perfumes, which, if they neither decomposed the organic poison nor killed the germs, would delight and not distress the patient. Dr. Wilson's card, although recommending fumigation, does not omit to recommend ventilation and to enforce the necessity of it, and herein he has our most cordial assent.

In fine, if the atmosphere of a room be foul, let it out; which is the cheapest and wellnigh the only practicable, if not the only possible, method of improving it. The proper sphere of disinfectants is the solids and liquids which harm us either by direct contact with our bodies or by their proximity to us and action on us through the atmosphere, the purity of which may to a great extent be preserved by suitable means. How this may be done will form the subject of another notice.

* Reprinted from the *Lancet*, Sept. 30, 1871.

* Some notion of the quantity of chemical substance requisite to effect a real disinfection of the atmosphere of a dwelling-room of ordinary dimensions may be gathered from a recent Oxford disinfection minute, which prescribes 4 oz. of sulphur to be burnt in every 100 cubic feet of air. Sulphur yields twice its weight of sulphurous acid, so that there would be about 80 litres of sulphurous acid gas to 3000 litres of air, equal to 2·6 vols. of gas in 100 vols. of air. The minute informs us that "no disinfection of this kind is thorough if a man can live in the room whilst it is going on," from which we see that it cannot be resorted to for the sake of the atmosphere in the room (which must be sent up the chimney or out of the window, and replaced by fresh air, before the room becomes habitable), but for the sake of the walls, and ceiling, and clothes hung up on poles, etc. In short, it is a method of treating the solids.

The Pharmaceutical Journal.

SATURDAY, OCTOBER 14, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed* "*Pharm. Journ.*"

THE CHIPPENHAM CASE.

THE question, as to the propriety of using a strong solution of corrosive sublimate for the cure of ringworm, would be so much more appropriately discussed in the columns of a medical journal, that we rejoice to find Dr. Fox's letter of this week is to be a final one; and, for the sake of Dr. MEERES, we hope the matter will now be allowed to drop. In taking leave of it, we note with pleasure the unanimity with which our medical correspondents recognize the service not unfrequently rendered by pharmaceutists both to the writers of prescriptions and to the patients for whom they are intended. Most of our readers who have had any large experience in dispensing will be able to call to mind instances, such as those mentioned by "Thirty Years M. P. S.," where that service has been most signally beneficial. But we agree with Dr. Fox in thinking this somewhat irrelevant to those points in the Chippenham case which were commented upon by "M. P. S.," and we are equally of opinion that Dr. Fox's indignation was irrelevant to the remark of "M. P. S.," which seems to have been so obnoxious; for even if that remark were unfounded, what would be more natural in the case of one who did not "set himself up as a judge of therapeutics as against properly qualified physicians"?

As we understand it, the real purport of the letter signed "M. P. S." was to urge the necessity of promoting a kindly feeling between medical men and pharmacists, inasmuch as both have duties to perform involving serious responsibilities and the possibility of mischances capable of being disastrous to themselves and to others. As already stated, we do not by any means adopt the views of our correspondent "M. P. S.," and in justice to him it must be remarked that he wrote under the influence of the verdict found by the jury in the Chippenham case; but we thoroughly agree with his conclusion, and are convinced that whatever grounds there may be for dissatisfaction between medical men and pharmacists, they are more likely to be removed by the exercise of mutual consideration than by indulging in contemptuous cynicism.

While speaking of this matter we cannot refrain from noticing Dr. Fox's complaint that our correspondents miscall his bichloride preparation "a lotion;" and it seems to us this is an apt illustration of that perversity which does so much to frustrate protective regulations against accidental poisoning. Just in the same way that Dr. Fox's "parasiticide" is called a lotion, do people sometimes swallow an embrocation in place of a cough mixture, and ignore the "poison bottle" as much as it would seem is the case with Dr. Fox's preventive classification.

We prefer leaving to the consideration of medical critics the efficacy of skin *tanning* as a preventive against absorption.

"CORASSA COMPOUND."

A GENTLEMAN to whose name the initials M.D., LL.D., etc., are appended appears to have recently provided, for the benefit of the American public, a preparation which he calls the "Corassa Compound." An inquiring correspondent of the Chicago *Pharmacist*, having met with a sample in the course of his business, took the trouble to examine it, and reports the result to that Journal. Upon placing the specimen—which appeared to be of a light fawn colour, resembling Dover's Powder—under the microscope, it was found to consist of three powders of different colours and degrees of division. These were separated by sieves of the requisite fineness, and proved to be gentian, sugar, and cochineal in about the following proportions:—

Powdered Sugar . . .	24
" Gentian . .	8
" Cochineal . .	1

There is just a *soupçon* of surprise perceptible in this gentleman's information, that the preparation is sold at three dollars (about twelve shillings) an ounce; but he has evidently lost sight of the string of consonants following the maker's name. Some of our correspondents have been occasionally so unsentimental as to express doubts whether in the acquisition of honorific titles the game is worth the candle. We hope they will be comforted and encouraged by this fresh evidence of the intrinsic value of such distinctions.

THE botanical library of the late Professor LINDLEY, which was purchased out of the surplus funds of the International Horticultural Exhibition of 1866 and deposited in the rooms of the Royal Horticultural Society at South Kensington, has been arranged and catalogued. Considerable additions have been made to the library by gift, and it is intended to serve as a nucleus of a consulting library for the use of gardeners and others. The trustees have just issued a circular stating that the library is now open for the use of the public under certain regulations.

Transactions of the Pharmaceutical Society.

The following is a list of donations to the Library to October 4th, 1871:—

Chemistry: General, Medical and Pharmaceutical, including the Chemistry of the United States Pharmacopœia: from Professor Attfield (Author),—Calendar of King's College, London, for 1870-71,—Edinburgh University Calendar, 1871-72,—Reports of the Thirty-eighth, Thirty-ninth and Fortieth Meetings of the British Association for the Advancement of Science: from Mr. Bremridge,—Introductory Address, delivered at the opening of the Session 1870-71, Queen's College, Birmingham: from Dr. Alexander Fleming,—The Ninth Annual Report of the Birmingham Free Libraries' Committee, 1870,—Reports, etc., of the West Kent Natural History, Microscopical and Photographic Society, 1870,—Report on Barracks and Hospitals, with descriptions of Military Posts: from the Surgeon-General, U. S. War Department,—Proceedings, etc., of the American Pharmaceutical Association, 1870,—Sketch of the Present State of our Knowledge respecting the Action of Mercury on the Liver: from Dr. T. R. Fraser,—On Dyspepsia, by Dr. Le Guillon,—Coleccion de Medicamentos Indigenas y sus aplicaciones, por Geronimo Pompa; Cuarta Edicion (Notulas adjunxit G. A. Ernst): from Dr. Ernst,—La Matière Médicale à l'Exposition de 1867, par J. Léon Soubeiran et Augustin Delondre; Histoire Botanique et Thérapeutique des Salsepareilles, par Ed. Vandercolme: from Dr. Soubeiran,—General Index to the first Fifty-three Volumes of the Medico-Chirurgical Transactions: from the Royal Medical and Chirurgical Society,—Annual Report of the Board of Regents of the Smithsonian Institution, 1869,—De l'Alimentation des Enfants et des Adultes dans une Ville assiégée et en particulier de la Viande de Cheval, par Edme Bourgoin; Des Alcalis organiques, par Edme Bourgoin; Du Blé, sa Valeur Alimentaire en Temps de Siége et de Disette, par Edme Bourgoin; Recherches Chimiques et Physiologiques sur la Nature des Principes purgatifs du Séné de la Palte, par E. Bouchat et Edme Bourgoin: from M. Edme Bourgoin,—Naval Hygiene, by Joseph Wilson, to which is appended, Moving Men on Shipboard, by Albert C. Gorgas: from the Medical Department U. S. A.,—Ueber Stärke und Cellulose; Uebersicht der Cinchonen, von Dr. Weddell: from Dr. Flückiger,—The Pharmacist (seven numbers): from Mr. D. Hanbury,—Om Marienbad dess Helsokällor och Bad; Om Karbolsyra: from Dr. N. P. Hamberg,——Bombardement du Muséum d'Histoire Naturelle de Paris par l'Armée Allemande en Janvier, 1871: from the Société Botanique de France,—Notes on the Quinquinas, by H. A. Weddell: from Mr. James Collins,—De l'Organisation de la Pharmacie dans les Principaux États de l'Europe, par C. Labélonye: from Mr. E. J. T. Agnew.

Provincial Transactions.

NORWICH CHEMISTS' ASSISTANTS' ASSOCIATION.

The Annual Meeting of the above Association was held at the Rooms, September 25th.

The President, Mr. Alfred Hill, in opening the meeting, said it was not his intention to detain them with an address, as the progress of the Society would be laid before them in the various reports. In the unavoidable absence of the Treasurer, he called upon the Vice-President to read the Financial Report.

Treasurer's Report.

Latin Tutor	4	5	0
Balance in hands of Treasurer	3	10	2
	£55	15	6

The Vice-President, Mr. E. Nuthall, then drew the attention of the meeting to the fact that the amount paid by the members of the Latin class fell far short of that which had been paid the tutor by the Association, and stated that this deficiency was mainly caused by four members declining to pay the fees.

Mr. F. D. Smith said that his presence there that night was owing to his desire to clear up a misunderstanding which evidently existed between the Council and the four members just mentioned. These latter were in his employ, and they stated that they did not feel themselves called upon to pay any fees beyond the annual subscription to the Association, as when the Association was formed it was stated that Latin would be included among the subjects taught by the Association.

Mr. Nuthall related in full the history of the Latin class, stating that such a class had been started by a member of the Association, but as the pupils expressed preference for a paid tutor, and offered to pay extra fees for the same, the Council entered into an engagement with Mr. Lowe. Before the commencement of each course the students were informed what fees would be required of them, and he maintained that it was scarcely justifiable for any of the gentlemen to take advantage of the class and then decline to pay.

These statements being borne out by the members of the Latin class present, after further discussion, in which Messrs. Tooke, Martin, Mason and Lincoln took part, Mr. Smith declared himself satisfied that the young men ought to pay unless they were willing to be considered as defaulters.

The President then called upon Mr. Nuthall to read the Secretary's report.

The report of the Materia Medica class, under the care of Mr. A. J. Caley, was very satisfactory. It met during the past winter months. The members were attentive and well-conducted. The class assembled nineteen times, and the average attendance was sixteen.

Eighteen evenings during the past winter and spring were devoted to the Botanical class, under the care of Mr. Octavius Corder; at first it was well attended and considerable interest displayed by those present, but towards the close the numbers fell short of what was anticipated. The average attendance was rather above thirteen.

The course of botanical studies embraced both structural and general botany, as also a description of the Natural Orders required by the Council of the Pharmaceutical Society.

The General Chemistry class, which was held during the winter months under the care of Mr. Nuthall, met twenty times, and the average attendance was twelve. At the outset the number of students was much larger; but as the charm of novelty wore off, and it became apparent that the class supplied but little assistance for a "Minor Cram," the attendance diminished. To those few who attended the entire course, great praise is due for their application. The course comprised chemical physics, the practical consideration of sp. gr., the laws of combination by weight and volume, chemical nomenclature and notation, the properties of the gaseous elements and of the metals of the alkalies and alkaline earths, together with practical testing for the latter.

The Latin class met during the first six months of the present year, and the course consisted of those subjects required for the Preliminary Examination, but only three students were sufficiently prepared to enter for it. The class nominally consisted of eleven pupils, but after the passing of the three gentlemen mentioned, only six members were left, two having discontinued their attendance.

The Library has been open thirty-six times for the purpose of renewing and exchanging books, since the first issue on February 27th.

It at present contains sixteen volumes, which have been circulated among nineteen members. It is found that such books as Attfield's 'Chemistry,' Bentley's 'Botany,' etc., which are best adapted to the requirements of those preparing for the Minor Examination, are preferred by the majority of members, as it is frequently necessary to give notice in order that these books may be secured.

The bye-laws relative to the Library and Museum meet with general satisfaction. It is thought, judging from the manner in which the library of this Association is appreciated, that it has already proved beneficial.

In addition to the regular classes, other sources of instruction have been provided, consisting of three lectures by Mr. F. Sutton on Chemistry; four on Pharmacopœia Tests, by Mr. A. J. Caley, and three on Chemistry, by Mr. Nuthall. A monthly botanical gossip, conducted in the spring by Mr. O. Corder, was discontinued in consequence of inattention displayed by members. Three pharmacy gossips were also conducted by Mr. Nuthall.

Very few members have passed examinations during the past year (namely, one the Major, two the Minor, and four the Preliminary). This is accounted for by the fact that the senior members, with one or two exceptions, had passed either the Minor or Modified Examinations before the formation of this Association. But it is expected that many of the apprentices will be enabled to pass during the ensuing year.

There is another source of information which is almost uniformly neglected. Through the kindness of several members and honorary members there is a large collection of loan books for use on the establishment; but these are rarely removed from the shelves, the members not yet having learned to consider this as a reading-room after class hours.

Besides the donations noticed in the Treasurer's Report, the following donations, etc. have been received:—

A grant from the Pharmaceutical Society of £8. 8*s*. for the purchase of botanical and chemical diagrams, the same remaining the property of the Pharmaceutical Society for three years.

The Pharmaceutical Journal: from the Pharmaceutical Society.

Engravings of the late Dr. Pereira, William Allen, and Jacob Bell: from Thomas Hyde Hills, Esq.

Valuable Book of Prescriptions: from J. Ince, Esq.

Collections of loose Prescriptions: from Mr. Fox, Leamington, and Mr. Attmore, King's Lynn.

A Collection of Chemicals: from Mr. Robinson, Orford Hill.

Several Materia Medica Specimens: from Messrs. Caley and Corder.

Several books: from Mr. N. Lincoln.

Volumes (bound) Pharmaceutical Journal: from Mr. J. English.

The Vice-President said the cause of his reading these reports was owing to having, with the valuable assistance of Mr. Mason, undertaken the duties of Secretary during the past five months, in consequence of the difficulty that had occurred in finding a successor to Mr. Grimditch.

When the report had been read, Mr. F. D. Smith said that after the account of so much work done, he felt compelled to propose a vote of thanks to Messrs. Sutton, Caley, Corder and Nuthall, who had given up so much time for the various classes and lectures. Seconded by Mr. Neal.

Mr. De Carle moved a vote of thanks to the honorary members, to whom the success of the Society, in a pecuniary aspect, was to such a great extent due. Seconded by Mr. T. C. Pitts.

Mr. Smith, in acknowledging the same, said that however much the financial success was owing to the support of the honorary members, the ultimate success depended upon the young men themselves, and he expressed a hope that during the ensuing year the attendance of students would be larger and more regular than exhibited in the report.

Votes of thanks were also passed to the donors who had come forward so liberally in commencing the Society; Mr. Ellwood for undertaking and ably carrying out the duty of Librarian; and to Messrs. R. C. Pitts and Gardiner for the careful manner in which they had audited the accounts.

The President now explained that the object of holding this meeting a week before its proper time was to ascertain whether the members were desirous of carrying on the Association another year. He thought that the falling-off in attendance which had been noticed, indicated a lack of interest on the part of the members, and unless there seemed a prospect of a change in that respect, he thought they would scarcely be justified in asking the honorary members to continue their subscriptions.

It was unanimously resolved to carry on the Society.

The President then stated that although the present Council would retain their functions until the end of the month, it was thought advisable to elect their successors at the present meeting.

Mr. Tooke said before they proceeded in the election of new Councillors, he thought it incumbent upon them to express their gratitude to the then existing Council for their unremitting and successful efforts in promoting the welfare of the Association, and proposed a vote of thanks to them collectively. This was seconded by Mr. Neal.

After the President had returned thanks, Mr. Lincoln said he had not anticipated that the meeting would allow their Council to be disposed of in one vote, and for his part must propose a separate vote of thanks to Mr. Nuthall, remembering that it was owing to him and Mr. Perkins that the Association had been started; seconded by Mr. Woolnough.

Mr. Nuthall briefly acknowledged the compliment.

The following gentlemen were then elected officers for the ensuing year:—*President:* Mr. Alfred Hill. *Vice-President:* Mr. Edwin Nuthall. *Treasurer:* Mr. W. J. Gooch Butler. *Secretary:* Mr. George C. Fox. *Council:*—Messrs. Canham, Goodenough, Elwood, Lincoln, and Martin.

After a spirited discussion, and various divisions, it was resolved that the class teachers be requested to restrict their subjects to those required for the Minor Examination; that the rooms be open three nights a week in the winter months; that the Preliminary class be held at the rooms; and that the pupils of the latter class be assisted in engaging a tutor, as far as possible, from the funds of the Association.

After a vote of thanks to the Chairman, the meeting dissolved.

LIVERPOOL CHEMISTS' ASSOCIATION.

Annual Meeting.

Session 1870–71.

The Annual Meeting was held at the Royal Institution, September 28th, 1871; the President, Mr. John Abraham, in the chair.

Mr. Robert Jennings was elected a member, and Messrs. George H. Damsell, Thomas Banner, jun., and Henry S. Shelmerdine were elected Associates of the Association.

The Hon. Secretary then read the Annual Report.

Annual Report.

In laying before you the Twenty-Second Annual Report, your Council have still cause to congratulate you upon the continued usefulness of your Association.

During the past Session 10 members and 6 associates have been elected; 10 have resigned, or by death or removal have ceased to belong to our ranks, leaving 127 at present on the roll.

The Chemistry Classes, in connection with the School of Pharmacy, have been conducted by Mr. Edward Davies, F.C.S., etc., and his Report gives your Council great encouragement for the continuance of them. The Materia Medica and Botany Classes, conducted by Dr. Carter, B.Sc. F.R.C.S., your Council regret have not been so well attended. The Chemistry Classes will be continued during the winter months by Mr. Davies, whose attainments and ability in teaching give an assurance of the greatest efficiency, and your Council will make arrangements for holding Materia Medica and Botany Classes during the spring and summer months.

The papers read at the fortnightly meetings have attracted considerable interest, and much information has been elicited during the discussions which followed. The majority of subjects have been connected with scientific chemistry. Your Council will be glad to receive papers during the ensuing Session upon subjects more intimately connected with pharmacy, materia medica, and botany; they also invite more miscellaneous communications from members who have not yet advanced the interests of the Association by assisting its objects in this way, and short papers by those who do not wish to occupy the entire evening.

Your Library has been enriched during the past Session by the appropriation of the grant from the Bell and Hills fund; a valuable collection of MS. prescriptions from Joseph Ince, Esq., F.C.S., F.L.S., etc., of London, and several other important contributions, and your Council congratulate the Association upon the fact, that the Library is so well stored with standard works upon chemistry, materia medica, botany and pharmacy, that it was found difficult to determine what books could be advantageously added, and they are mainly indebted to Professor Attfield for the selection. The Librarian reports that many members have availed themselves of the advantages of these valuable stores. 300 books have been taken out during the Session, and several applications have been made for the leading works which could not be met, and your Council are glad to find that the Library is of great service to members who make constant use of it for reference.

Your Association was invited to send a deputation to meet the Committee of the Liverpool School of Science, to discuss the advisability of establishing a science college in Liverpool; your Council appointed a deputation, but nothing definite has resulted.

In compliance with the instructions of an ordinary meeting of the Association, your Council called a meeting of the chemists and druggists of Liverpool on the 10th of March, "To consider the proposed compulsory Regulations for the keeping, storing and dispensing of Poisons," at which resolutions were adopted adverse to *compulsory* regulations, and they were forwarded to the President of the Pharmaceutical Society.

The Funds of your Association have been enriched by the liberality of the Local Committee of the British Pharmaceutical Conference, and this enabled your Council to hold their eleventh conversazione, at which about 400 members and friends of the Association assembled. Your Council are indebted to Professor Roscoe, F.R.S., for his exhaustive lecture upon "Solar Chemistry," illustrated throughout by numerous beautiful experiments; to Mr. Edward Davies, F.C.S., etc. for his interesting and illustrative lecture upon "Modern Explosive Compounds;" to Mr. Albert H. Samuel for his illustration of "Tyndall's Theory of the Cause of the Blueness of the Sky," and to the several microscopists and contributors of scientific novelties, etc. which enabled your Council to entertain their guests in such a manner as to make this one of the most successful conversaziones ever held by the Association.

Your Council were invited to send delegates to the meeting of the British Pharmaceutical Conference at Edinburgh in August, and Messrs. Shaw, Mason and Dr. Edwards attended as a deputation from your Association.

The following members of Council retire by rotation, and are eligible for re-election:—Messrs. Abraham, Redford, Shaw and Sumner.

Your Treasurer will present a report of the finances of the Association which shows a credit balance of £9. 4*s*. 10*d*.

The Treasurer read the financial report.

Financial Report.

Albert Henry Samuel, } *Auditors.*
Charles Sharp. }

Mr. Charles Jones moved "That the Report as read be adopted, and together with the Transactions of the General Meetings, the Laws and Bye-Laws, the Catalogue of Books in the Library and the List of Members, be printed and circulated among the members." He was pleased to hear that the classes in connection with the School of Pharmacy had increased, in comparison with former sessions, and as it was the principal part of the business of the Association to provide classes for Pharmaceutical students, he hoped they would continue to avail themselves of these advantages. He congratulated the members upon being in possession of so valuable a library, to which he hoped they would soon be able to add Sowerby's 'Botany.'

Mr. ALFRED E. TANNER seconded the resolution, which was carried unanimously.

The meeting then proceeded to the election of four members of Council in place of Messrs. Abraham, Redford, Shaw and Sumner, who retired by rotation.

The result of the ballot was that the retiring members were re-elected.

The PRESIDENT stated that at the end of the session Mr. Davies invited the students in the Chemistry Class to attend voluntarily a written examination, the result of this was so gratifying that he and Mr. Davies had decided to award prizes to the two students who obtained the highest number of marks; he had therefore much pleasure in presenting the first prize, Pereira's 'Materia Medica,' to Mr. Abbott; the second, Bowman's 'Practical Chemistry,' to Mr. Jackson.

Mr. REDFORD moved, "That the best thanks of this meeting be given to the donors to the Library and Museum, and to the authors of papers during the past session."

Mr. F. TAYLOR seconded the motion; carried unanimously.

Mr. CHARLES BLOOD moved, "That the best thanks of the meeting be given to the Officers and Council for their valuable services during the past session."

Mr. T. F. ABRAHAM seconded the motion; carried unanimously.

The PRESIDENT, TREASURER, and SECRETARY returned thanks.

A discussion arose upon the desirability of having a collection of MSS. prescriptions in the library. The Secretary referred to Dr. Syme's proposal of last session to fill up a book, if the Council provided one; it was finally decided to lay the matter before the Council, and announce their decision upon the circular calling the ordinary meetings.

A vote of thanks to the Chairman having been carried by acclamation, the meeting separated.

The following arrangements are announced for the Session 1871–72, of the School of Pharmacy, in connection with the Liverpool Chemists' Association:—

A course of lectures on inorganic chemistry, preparation of chemical products used in pharmacy, qualitative and volumetric analysis, by Edward Davies, F.C.S., etc., lecturer on experimental physics in Queen's College. Each lecture will be followed by questioning upon the previous lecture, and will be illustrated with experiments.

The course will commence on Friday, October 13th, from 5.30 to 7.0 P.M., and will be continued on successive Fridays until the end of March, 1872, at the laboratory, 17, Back Colquitt Street (off Seel Street). Fee for the course, one guinea.

Pharmaceutical Students will be received at the laboratory for the study of practical chemistry, at any hour between 9 and 5 o'clock. Fee one guinea and a half for three months, two hours per week.

Students wishing to attend these lectures must send their names to Mr. Davies, at the laboratory, on or before October 13th, from whom further particulars may be obtained.

Arrangements will be made for holding classes in materia medica and botany during the spring and summer months, particulars of which will be duly announced.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Annual General Meeting of this Association was held on Wednesday evening, 4th instant, in Anderson's University; Mr. Thomas Davison, President, presiding. The attendance was good. After the usual preliminary business, the Secretary (Mr. J. M. FAIRLIE) was called upon, and read the—

ANNUAL REPORT FOR 1870–71.

Your Council has much pleasure in presenting an epitome of the proceedings of the Association during the past year; and they are proud to state that, in most respects, the Association has made a marked improvement on any preceding year. The membership has reached the large number of one hundred and thirty-six (upwards of thirty of whom are employers). This increase of about fifty to the membership of last session may be accounted for in several ways; first, the fact that we now hold our meetings in our own hall, and within the walls of Anderson's University; second, the necessity for education among the younger members of the business, and the very encouraging prospect your Society has of being able to carry out special classes suited to the wants of Pharmaceutical students; third, the great assistance your Association received from Dr. R. Carter Moffat, Professor Henneday and Dr. D. C. Black by lectures, etc., and the liberal support you have received financially at the hands of several of the wholesale houses, especially the Glasgow Apothecaries' Company, and last, though not least, the fact that Glasgow chemists generally have at length been aroused to a due sense of their position in regard to pharmacy in the kingdom.

The remodelling of the constitution and the raising of the annual subscriptions, were necessary adjuncts to the change in the place of meeting, and it is hoped that the care bestowed on the compiling of the several rules, may be felt and appreciated by their remaining the guide of future councils for many years to come; and we trust that the increased subscriptions, which, properly speaking, will commence with the ensuing session, may not debar any from joining us, but that every one will do their utmost to make next session even more successful in point of numbers than the one just brought to a close.

As usual a syllabus of business was issued at the commencement of the session, which was well adhered to throughout; fourteen meetings were held in all, and the average attendance could not be less than sixty. Mr. Hennedy's two lectures on "The Histology of Plants" was the first point of interest; then we had three lectures from Dr. Moffat of the usual instructive and interesting nature. The event of the session, however, was Dr. D. Campbell Black's address on the "Relation of Prescriber to Dispenser." This address was published in full in the PHARMACEUTICAL JOURNAL; several of the medical journals took notice of it by giving extracts and leaders favourably criticizing its contents; while your Society printed and circulated four hundred copies. All this speaks largely for the interest it created not only in and around Glasgow, but throughout the whole country. We believe it has been the means of bringing before the country, more prominently than anything else, the anomalous position in which the dispenser is placed in and around this large city; and we hope the day is not far distant when there shall be an entire separation of the two professions.

The several papers read by members of the Association and the discussions which took place at the meetings, will, we think, compare favourably with those of any other association of similar pretensions. One member specially deserves mention, he having prepared and read two very practical papers, and passed two of the Pharmaceutical Society's examinations in the course of the session, an example well worthy of imitation.

We are glad to record that the Annual Festival, which has always been such a prominent feature in our programme of business, came off this year with its usual success. Your Council would, however, recommend that, as an educated body, we should adopt some other means of meeting socially, and thus raise ourselves above the common mode of trade gatherings.

The revival of the poisons regulation question was another feature in the business of the session, and we were glad to notice that the example set by your Association, of "actions not words," was followed by other associations throughout the country, and that their combined action had the effect of causing the Council of the Pharmaceutical Society to withdraw the compulsory part of the regulations. This, however, did not complete the agitation on the question. At the Annual Meeting of the Pharmaceutical Society, held in May last, at which your President attended to watch our interest, the question was again brought up, and but for the determined efforts of Mr. Mackay, of Edinburgh, and some other leading gentlemen in connection with the Society, it was just possible they might have been forced upon us by a "side wind." But the defeat the advocates of compulsory regulations sustained at this point did not put an end to the question; either through some misleading idea of the medical officer of the Privy Council, backed, we are sorry to say, by some influential and respected gentlemen connected with the Pharmaceutical Society, or, perhaps, a determination on the part of some leading members of the present Government to lay down certain rules for our guidance, a Bill was introduced into Parliament, the history of which is no doubt known to all. Suffice it to say, that in Glasgow we had two very successful meetings of the trade, attended by both town and country members, at which no uncertain sound was given regarding this question, and out of which sprang the "West of Scotland Chemists' Defence Association." This body sent a deputation to London, also a petition to Parliament against the Bill, signed by sixty-five Registered Chemists within the city in eight hours' time, besides circulars, addresses and memorials to the trade in Scotland, members of Parliament and to the Government. The thanks of the whole trade are due to the executive of this Association, to the members of the trade in Scotland who subscribed so liberally to its funds, to the London and Manchester Defence Associations for their invaluable aid, to William Graham, Esq., M.P., for taking charge of the petition in the House of Commons, and to the other members of Parliament who exercised what influence they could with Government in inducing them to withdraw the obnoxious Bill. We sincerely hope that compulsory regulations for the *storing* of poisons are among the things of the past; but should they come up again, our opponents must know that we are ready to fight the battle over again if need be.

In referring to these matters, we have departed from the usual course of giving simply a record of the transactions of the Association; but they are so intimately connected with ourselves as individuals, that we thought it would be out of place not to refer to them on this occasion.

Returning to the business of the session, we have next to refer to the botany class, commenced in the spring of the year, and conducted by Professor Henneday. Twenty-eight members came forward and joined the class; and, so far as they have gone, Mr. Henneday speaks favourably of them. The class will be resumed on the first Monday of November, for preparation for the Science and Art examinations. But, until these examinations come off in May next, we cannot speak confidently of the progress that has been made.

We have no record at present of the numbers connected with the Association who have passed the various examinations of the Pharmaceutical Society in course of the year. We know, however, we are still behind many of the larger towns in England in this respect, but we hope ere long to stand on a par with our brethren of Liverpool and Manchester; and the fact that a large number of employers in and around Glasgow became members of the Pharmaceutical Society in course of the year, and that we have now a representative in the London Council in the person of Mr. Frazer, augurs well for our future prospects.

The dispensing price-list issued by your Association at the beginning of the session has been freely circulated to both town and country members of the trade, and we are glad to notice that very many have adopted both price-mark and prices; but there are still some who have not yet done so, and we would earnestly urge upon them the necessity for helping us in this good work by their example. Our trade-mark, "Mel Boracis," is well known throughout the trade; and there is no reason why every chemist in the kingdom should not adopt it, so that a universal price-mark and prices might be the rule.

We have to acknowledge the receipt weekly of the *Pharmaceutical Journal*, also the *Chicago Pharmacist* and the *Chemists and Druggists' Advocate;* and the best thanks of the Association are due to the proprietors of these journals. They are open to any member of the Association who may wish a perusal of them, by applying to the Secretary.

We have also to acknowledge the receipt of the book of autograph prescriptions prepared by Mr. Joseph Ince, of London, for your Association; and your Council recommend that a special vote of thanks be awarded that gentleman for his courtesy and kindness to us of late.

The delegates from your Association which attended the British Pharmaceutical Conference meeting at Edinburgh report a successful meeting, and your Council wish all success to the Conference.

As regards the prospects for the ensuing session, they are very bright indeed. The commencement of a chemistry and a materia medica class may be announced shortly; and it is hoped that the members will support and encourage this educational movement by every means in their power. The changing of the Treasurer in course of the session was a source of grief to your Council, but it is hoped that you will select gentlemen for the various offices in future who are likely to keep office for at least one full session. It is expected that Mr. Stanford, of the British Seaweed Company, will deliver the opening address; and several members have already offered to read papers. Several discussions will take place on pharmaceutical matters upon which there exists a difference of opinion, and it is hoped that, when the subjects are announced, members will prepare themselves to take part therein. The long business hours in many of the establishments have long been felt a great barrier to any real progress being made, either in educational or other pharmaceutical matters. The Committee appointed in course of the session to endeavour to bring about some improvement in this respect, went heartily to work at first, but through the agitation on the poisons question, and other circumstances over which your Association had no control, no active measure was able to be carried out; one point, however, was elicited in course of the canvass made, viz. that very many employers are most anxious for some reformation in this direction. We want, however, unanimity, and we are sure the excellent example set by the larger places of business in the central part of the city is worthy the serious consideration of all; and let us hope we may yet have the much-desired short-hour movement carried on as a whole, not only in this city, but throughout the whole country.

In conclusion, we would offer a word of advice to the younger members of the Association, and while doing so we would express regret at the fact that, during the session, the papers delivered by members were not so numerous as in some former years of the Society's existence. But when we remember that members have now compulsory examinations before them, which formerly they had not, we can see that they will be apt to think they do very well if they prepare themselves for their respective examinations, without turning their attention much to testing for adulterations, or the best mode of preparing particular preparations. We would respectfully remind you, however, that this is as much part of your education as that of being able to detect unusual doses in prescriptions, or being able to translate a Latin récipe correctly; and further, that our Association meetings are as much a training-school for students in pharmacy as the class-room or the laboratory. We earnestly urge you, therefore, to keep up the interest of our fortnightly meetings by some practical papers, as well as by your attendance. Those who have already begun, we would encourage to persevere; those who have as yet done nothing, we would ask to make a beginning this year. You have advantages which very many of your employers never had. You will certainly find some difficulties to contend with, but success is invariably the reward of perseverance; and though you may not accomplish much at first, bear in mind that great things generally have small beginnings. The largest river in the world, we are told, takes its rise as a mountain spring; the giant oak was once a slender twig. The whole world, we know, is made up of molecules and atoms. Then let each of us perform our part, however humble, nothing daunted: above all, let us be united in our aims for the advancement of our profession; it is a noble cause; and if we work earnestly, there is no doubt but that we shall have our reward."

The financial statement was then submitted as follows:—

RECEIPTS.

	£.	s.	d.
Balance from last year	5	6	1½
Donations of 10s. and upwards	11	14	6
Subscriptions from 136 Members	9	15	0
Botany Class, Fees, Books, etc.	10	8	6
Soiree Accounts	44	14	6
Total	£81	18	7½

EXPENDITURE.

	£.	s.	d.
Hall Rents for Meetings, etc	9	17	6
Printing Account	9	19	6
Postages, etc.	2	4	3
Botany Class	11	11	3
Soiree Accounts	43	8	0
Balance on hand	4	18	1½
Total	£81	18	7½

Audited and found correct, showing a balance of £4. 18s. 1½d. in Treasurer's hands.

(Signed) JOHN FENWICK, W. S. GALBRAITH. } *Auditors.*

Glasgow, October 4th, 1871.

After some questions had been asked and answered by the Secretary, Mr. JOHN BLACK moved the adoption of the reports, which was seconded by Mr. WILLIAM WHYTE, and unanimously agreed to.

The following gentlemen were elected officers for the ensuing year:—viz. Mr. T. Davison, President; Mr. R. Brodie, Vice-President; Mr. William Young, Treasurer; Mr. J. M. Fairlie, Secretary. Council—Messrs. D. Frazer, J. Jaap, Alexander Kinninmont, John Black, William Whyte, A. E. Johnstone, John Fenwick, A. Paterson, J. Clark, A. Gardner, J. L. M'Millan and Dr. R. Carter Moffat. Auditors—Messrs. John M'Millan and R. T. Dun.

It was afterwards agreed that the annual general meetings be held in April of each year in future, instead of October as hitherto. The Secretary was instructed to convey to the Glasgow Apothecaries' Company and Mr. Joseph Ince, London, the best thanks of the Association for their donations.

Motions were then tabled for next business meeting; first, to alter the name "Glasgow Chemists and Druggists' Association" to that of "Glasgow Pharmaceutical Association;" second, "that the Council be instructed to make application for a grant of money to the Council of the Pharmaceutical Society at London for this Association." Remarks were then made by the Chairman, Messrs. Kinninmont, Paterson and others, and the meeting separated.

THE MIDLAND COUNTIES CHEMISTS' ASSOCIATION, BIRMINGHAM.

On Wednesday evening, the 4th of October, a meeting was held in the rooms of this Association (24, Quadrant, Birmingham) of the chemists' assistants and apprentices of Birmingham. Two hundred invitations were issued by the President, Mr. George Dymond, who also provided coffee and refreshments. The object of the meeting was to draw the attention of young men to the scheme which the Council of the Association had matured for a series of classes and lectures specially adapted to pharmaceutical students in connection with the Birmingham and Midland Institute; the "School Committee" of the Institute having generously placed their educational appliances at the disposal of the Association for this purpose.

About seventy young men responded to the invitation, and the proceedings were characterized by considerable enthusiasm and interest. The programme of lectures, etc., published in last week's PHARMACEUTICAL JOURNAL, was unanimously approved and accepted, and thirty gentlemen at once gave in their names as candidates for one or more of the courses. Committees were also appointed to canvass the assistants and apprentices of the town and neighbourhood, and to urge upon employers the duty of closing their establishments in time to liberate their *employés* to attend these lectures. The lecture season, thus vigorously commenced, will, it is hoped, prove a successful renewal of pharmaceutical life in this metropolis of the Midland Counties, where great facilities exist for study, and for the qualification of young chemists.

On Friday, the 6th of October, the usual monthly meeting of the Council of the Association was held, the President in the chair. At this meeting it was determined to hold a conversazione during the winter months in Birmingham. Due notice will be published as soon as the arrangements are complete, and tickets issued, which will admit a gentleman and lady. A large attendance is anticipated from Birmingham and the Midland Counties; and it is hoped that visitors from more distant places will also be present.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSISTANTS' ASSOCIATION.

A General Meeting was held in the Council-room, Mitre Chambers, on Thursday evening, October 5th; the President (Mr. W. LANE) in the chair.

In commencing the business of the evening, the PRESIDENT, after referring to the success of last session, urged each member, individually, to do his utmost to prevent this being less interesting than its predecessor. He also drew attention to the advantages afforded by the Owens College classes in connection with this Association, viz. chemistry, botany, pharmacy, etc.

The Secretary (Mr. CLARKE) then read the rules, with several alterations suggested by the Committee, which were afterwards passed as read; the principal rearrangement being, that the meetings be held on alternate Tuesday evenings instead of weekly as heretofore.

Several new members were elected, and the first ordinary meeting arranged for Tuesday, October 17th.

HULL CHEMISTS' ASSOCIATION.

The Committee of the Hull Chemists' Association announce that the third winter course of twenty-six lectures, comprising elementary chemistry, materia medica, pharmacy, translation and rendering of prescriptions, etc. will be delivered by W. A. Rudd, Esq., M.R.C.S., in the Society's Room, Albion Street, on Thursday evening, October 26th, at 8.15 precisely, and continuing weekly at the same place and hour. Fee for the course, £1. 1s. Intending students are requested to send in their names as early as convenient to Mr. James Baynes, President, or Mr. Charles B. Bell, Honorary Secretary, who will furnish further information if required.

The course of instruction will have special reference to the requirements of the Minor examination of the

Pharmaceutical Society, which it is now incumbent on all chemists and druggists to pass before commencing or taking charge of a business.

The Committee state that a year ago they expressed a hope that important advantages might eventuate, to efficiently conducted local associations, from the deliberations of the Sub-Committee of the Council of the Pharmaceutical Society on technical education; they regret, however, that as yet no satisfactory result appears to have been arrived at, arising probably from the distracted state of the Society and the trade during the recent agitation.

The following extracts from the reports of the lecturers will be read with interest, as marking the progress of the local Association.

Mr. Rudd, speaking of the materia medica, chemistry and pharmacy class, says, "It affords me much pleasure to be able to state that the class is eminently successful. In the first year we had 18 students, and last session 20, the average attendance being 16. With few exceptions the conduct and attention of the class was commendable. At the examination for prizes, the replies of the candidates and the excellent character of most of their papers, plainly evinced that the gentlemen who took the prizes were desirous of attaining a knowledge of the subjects taught, and had been attentive and *industrious* students, and so in accordance with the maxim '*Qui palmam meruit, ferat*,' the prizes which they had honourably won had been awarded to them. I believe most of these prizemen would pass the Minor examination at once. In the first session four prizes were offered for competition, this year (under special circumstances) six were awarded as follows:—

"Senior materia medica, Mr. Bell, presented by Mr. C. P. Gibson; ditto, second prize, Mr. Sharrah, by Mr. A. Smith; junior materia medica, Mr. Hindson, by Mr. C. B. Bell; senior chemistry, Mr. Holroyd, by Mr. J. Baynes; junior chemistry, Mr. Thompson, by Mr. Rudd; perseverance, Mr. Pearson, by Messrs. F. Earle and J. Baynes.

"Mr. Bell obtained the highest number of marks in both chemistry and materia medica, and his written paper was of the highest order. It is to be regretted that a greater number of the class did not compete; and I would urge masters and employers to encourage those about them, who have given any attention to their studies, to enter for the examinations, because if they are not successful, the competitors gain an idea as to the kind of questions they may expect hereafter, and moreover become initiated into the style and manner of writing papers from memory. I am glad to report that our class-room is now large and convenient; we are gradually getting a supply of useful apparatus, charts, etc., and by adding from time to time other specimens, preparations and chemical instruments, we shall ultimately obtain a good museum of materia medica, and a useful laboratory; and thus be enabled to offer to students in the trade a practical course of instruction in all they need for their examinations, and this in the form of an agreeable and interesting meeting once a week."

Mr. Niven, curator, Hull Botanic Gardens, reports of his class, "The attendance has been much more regular than in the previous session, and the attention displayed by the young men has been of the most satisfactory character; out of the 18 students only on one occasion was the attendance as low in number as 12. The examination was held Sept. 1st, when four of the senior and seven of the junior pupils presented themselves. Mr. Bousfield obtained the senior prize, Mr. T. W. Robinson being nearly equal in number of marks. The junior prize was awarded to Mr. W. H. Lambert, with nearly double the number of marks as compared with the others. On the whole, the result of the examination, both as regards the number attending and the knowledge manifested by the replies given, was a great improvement on that which took place at the close of the previous session. The prizes awarded were,

"Senior botany, Mr. W. Bousfield, Bentley's Manual, presented by Mr. G. Myers; junior botany, Mr. W. H. Lambert, Bentley's Manual, by Mr. A. Pickering."

At the close of the present session it is intended to offer four prizes for competition, viz. senior and junior materia medica and pharmacy, and senior and junior chemistry.

Proceedings of Scientific Societies.

AMERICAN PHARMACEUTICAL ASSOCIATION.

The Nineteenth Annual Meeting of the American Pharmaceutical Association was opened on Wednesday, September 12th, at St. Louis (Missouri), in the hall of the Polytechnic building, corner of Chestnut and Seventh Streets.

The Convention was called to order about half-past three o'clock by the Secretary, Mr. John M. Maisch, who stated that in the absence of the President, first and second Vice-Presidents, and the death of the third Vice-President, it was necessary to elect a President *pro tem.* J. Farris Moore, of Baltimore, Maryland, was unanimously elected.

The list of delegates was then called, and the Committee on Credentials made their report.

Objections were made to the credentials of the Michigan University delegates being accepted, on the ground that the university was not a school of pharmacy. Its rule of graduation is different from that of other pharmaceutical colleges, as it bestows upon the student his certificate of graduation before he has served an actual apprenticeship in the practical department, thus giving him the title of "Pharmaceutical Chemist" while he has only a theoretical knowledge of the business.

The matter was referred to a committee of representatives present, one being selected from each college.

The retiring President congratulated the Association on its prosperity and the increase in the number of members since its foundation. He said the liabilities of the Association were now being paid off, and in another year they would be entirely extinguished. He recommended that a delegate should be sent to the Pharmaceutical Congress which is to be held at St. Petersburg in 1872, as he thought the information to be gained would fully compensate them for the expense.

In the evening the visitors were entertained at the Southern Hotel by the committee of St. Louis druggists.

A large hall in the building where the Conference met was fitted up for the exhibition of various objects of interest to pharmaceutists.

Parliamentary and Law Proceedings.

Suicide by Arsenic.

On October 7th, Mr. Booth, coroner, held an inquiry at Hanley as to the death of Mr. Clement Wooldridge, builder and brick manufacturer, who died on the previous day from the effects of arsenic, self-administered.

Miss Lavinia Wooldridge, deceased's sister, said her brother had been unwell for five or six months, and for several days had been peculiar, having a strange look in his eyes, and talking queerly. She had never heard him threaten to destroy himself, but for some days he did not seem to know what he was about. On Friday morning she found he had been sick, and, noticing a bluish colour in the vomit, asked him what was the matter, to which he replied "bile." Not being satisfied, she went for Mr. Folker, surgeon, who came in about half an hour. Deceased was sick again about two hours after, and continued so nearly the rest of the day. He talked wildly when spoken to. She saw a paper in the room, labelled "poison," but with nothing in it. She had no idea what he could have required poison for. They had dogs and rats, and deceased said two or three weeks ago that one of the dogs (a black one) would have to be poisoned. It had not been poisoned.

Mr. E. Parkes, chemist and druggist, Piccadilly, said deceased came to his shop on Wednesday, and said he wanted a little arsenic to poison a dog. Witness told him he must bring a witness to the sale, or he could not let him have it, though he knew him well, for the law must be complied with. He went out and returned with Mr. Kelsall, ginger-beer manufacturer, and witness then sold him an ounce of arsenic mixed; that is, equal parts of pure arsenic and a colouring powder. The purchase was entered in a book and signed by deceased and Mr. Kelsall. Mr. Wooldridge was not at all excited, and stood chatting with witness a few minutes after making the purchase.

Mr. W. W. Kelsall said he met the deceased on Wednesday about one o'clock. Mr. Wooldridge asked him to go to the Smithfield Inn and have a glass of beer, and he consented. On the way deceased went into Mr. Parke's shop, and presently came to the door and called to witness, to whom he said, "I want you to sign a book. I am going to poison a dog, and it requires some signing." Deceased had a very savage vicious dog, which had been sent him from Wolverhampton. Witness signed the book, and then they went to the Smithfield, where witness stayed till seven o'clock with deceased, whom he left there. Deceased was sober and was perfectly calm.

Mr. W. H. Folker, surgeon, said when he went to the house of deceased on Thursday morning his sister told him deceased had taken poison, and, looking round the room, he saw a paper with a "poison" label upon it, and a half-pint mug, which had a bluish sediment in it. He asked deceased if he had taken poison, and he replied, "Yes." Witness at once prepared an antidote, and asked the deceased to drink it immediately. He asked what it was for, and when told, said, "I will not take that or anything else, and if I get well I will take some more" (poison). He added, "I expected they would send for you, but I hoped I should have 'pegged out' before you came." The poison had begun to work before witness arrived, although deceased vomited again while he was there. He visited him again three or four times during the day, and administered several things, which deceased took in the hope of being relieved of the very great pain he suffered. It was impossible to save him after such a dose of poison. He had swallowed it two hours before witness saw him. Less than a hundredth part of the quantity of arsenic he took would kill a man. He had known deceased for some time, and he should never have suspected him of doing such a thing, but his manner and language when with him on Thursday, his saying he had taken poison and meant it, and if that did not answer he would take more, coupled with the taking of the poison, led witness to the conclusion that he was then not sane.

Mr. D. Groom, managing clerk to Messrs. Tennant, solicitors, said he had seen a great deal of Mr. Wooldridge during the last fortnight. On Wednesday fortnight he came to the office, and said he was glad witness had come back from his holiday, as he had been in trouble for a long time and was almost mad; he had neither been able to eat nor sleep for a long time. He came afterwards every day, sometimes twice a day, and when he came the second time he would ask again the question which had been answered in the morning, having apparently forgotten everything he had been told two or three hours before. About the middle of the previous week he came to the office and cried bitterly for an hour and a half. He continually complained of not being able to think of anything, to attend to his business, or to sleep, and said unless some disputes were arranged it would kill him.

The coroner having summed up and put tho issue before the jury, they found, after a few minutes' consideration, a verdict of "Temporary insanity."—*Staffordshire Weekly Times.*

Alleged Poisoning of a Child.

On Friday night, October 6, Mr. Richards resumed an inquiry at the Prince of Wales Tavern, Banner Street, St. Luke's, into the circumstances attending the death of William Jackford, aged nine months, the infant child of a woman living at 13, Baltic Street, whose death is alleged to have been caused by lead poison, administered by a woman with whom the child had been farmed. When the deceased was six weeks old it was farmed with a Mrs. Elizabeth Peck, who received 7*s.* a week (latterly reduced to 5*s.*) for its keep. This woman kept deceased until the 27th ult., on which day she took it back to the mother in a perfect state of health, according to her account. From the time the child was taken home it began to sicken, and vomited violently all the next day, dying in a fit of convulsions on Thursday night. Dr. Thomas Warder had made a *post-mortem* examination of the body, and found the stomach red and inflamed, with black specks all over it. These specks he had ascertained were lead, and he was, therefore, of opinion that the convulsions had been caused by lead-poisoning. He had kept the contents of the stomach for a chemical analysis, which he thought ought to be made, and the inquiry was adjourned for a week to enable a professor to make the necessary experiments.—*Daily News.*

Poisoning by Carbolic Acid.

An inquest was held on Tuesday last at Bangor to inquire into the death of a young woman named Jones. It appeared from the evidence that on the previous Saturday the deceased went to Mr. Baker, chemist, of Upper Bangor, and asked for two-pennyworth of carbolic acid for the purpose of cleansing a dress of some tar. Mr. Baker expressed his doubt whether the acid would not burn the material, but she wished, she said, to try it, and after informing her of its poisonous property, he supplied her with two drachms of the acid, placing a "poison" label upon the bottle, although, as he explained in answer to some remarks made by the coroner, carbolic acid is not included in the schedule of poisons necessary to be labelled. It is surmised that while walking home she tore the label off the bottle, pieces of it being afterwards discovered in her pocket. When or how she took the poison is not known, but she died in a very short time after coming back. A surgeon (Dr. Humphreys) was sent for, but he did not arrive while she was alive, and observing no appearance of anything unnatural, he attributed death to some ordinary cause. Subsequently, however, another surgeon, Dr. O. T. Williams, saw the body at the request of Mr. Baker, and then the bottle was discovered in the pocket of the deceased's dress. Neither of the medical men could say that death was occasioned by poisoning, the mouth being entirely free from the blistering that would be expected, and a *post-mortem* examination was therefore ordered by the jury. This revealed that the deceased had undoubtedly taken the carbolic acid, the stomach being greatly congested and corroded; but the doctors were of opinion that deceased died from suffocation caused by the closing of the glottis, which would account for the suddenness. The coroner was disposed to cast some reflection upon Mr. Baker for indiscretion, but the jury, in returning a verdict of "Temporary insanity," completely exonerated him from blame.—*Liverpool Mercury.*

Murder and Attempted Suicide by Poisoning.

A sad case of murder and attempted suicide of the murderer is reported. The Rev. T. Selby Watson, M.A., for twenty-five years head master of the Stockwell Proprietary Grammar School, having, according to his own account, killed his wife in a fit of fury, appears to have determined to poison himself by prussic acid. At the first chemist's shop at which he applied the drug was refused, although he was well known; but he was afterwards found weak and speechless, apparently suffering from the effects of poison. Medical assistance was procured and he recovered. A small bottle containing a very diluted mixture, but in which there were clear traces of prussic acid, was found on a chair by his bedside.

On Thursday Mr. Watson was brought before Mr. Ellison, at the Lambeth Police Court, charged with wilfully murdering his wife. Evidence was given that the prisoner was found in an unconscious state by a servant in his employ.

Dr. Rugg said that on Wednesday morning he was called to the prisoner's house, where he found him unconscious, slightly convulsed, breathing heavily and with difficulty. His eyes were fixed and turned upwards, pulse soft and compressible, and there was a cold, clammy perspiration. When he became conscious, prisoner told witness that he had taken prussic acid. Witness described the state in which the wife was found, and after some further evidence the case was adjourned for a week, to allow of a *post-mortem* examination.

Poisoning by an Overdose of Morphia.

An inquest was held on Tuesday last at Southampton upon the body of Solomon Norman, aged 56, a cabinet maker.

Dr. Scott said that on the previous Saturday he was called to see the deceased, whom he found completely insensible and breathing only at intervals. The pupils of the eyes were strongly contracted. Every effort to rouse him was unavailing. Witness believed that deceased had been in the habit of taking morphia or laudanum occasionally, and that his health was not very good. He had observed a 2-oz. bottle and cup on a chair near the bed, and in the bottle was a drop of clear liquid, like water, which had a bitter taste. It was labelled "Diarrhœa mixture," in deceased's own handwriting. He had no doubt, from what he observed, that the deceased had taken a large dose of morphia.

The coroner observed that the evidence already given left no doubt on his mind that the deceased had died from morphia.

Mr. James, one of the jury, stated that he knew the deceased personally. He was very much afflicted, as was shown by his features, and occasionally suffered great pain. Witness was under the impression that he took morphia or some other narcotic to assuage pain, and thought that he probably took an overdose without any other intention than to produce sleep and relieve the pain.

The jury returned a verdict that deceased died from taking accidentally an overdose of morphia.

Review.

Die Pflanzenstoffe: in chemischer, physiologischer pharmakologischer und toxicologischer Hinsicht. Für Aerzte, Apotheker, Chemiker und Pharmakologen bearbeitet. Von Dr. Aug. Husemann und Dr. Th. Husemann. Berlin. 1871.

The publication of this work, which has extended over a period of eighteen months, being now completed, we may briefly sum up the contents and mode of treatment of what will undoubtedly be in future the work of reference on all matters connected with the products of the vegetable kingdom employed in pharmacy. These products the MM. Husemann classify as follows:—A. Simple combinations: (1) bases on alkaloids; (2) acids, both those of general distribution, and those of special occurrence; (3) neutral substances, with the same distinction. B. Compound substances: (1) volatile oils; (2) resins; (3) fats. In each section the substances are arranged under the Natural Orders to which the plants producing them belong; and the authors enter, with more or less of detail, into an account of their discovery, mode of preparation, properties, composition, products of decomposition, behaviour with various reagents, and their physiological and toxicological effects. Of the sections named above, the alkaloids occupy by far the largest space, the immense importance of these bodies to physicians and pharmaceutists, for whose use the work is especially designed, justifying the greater minuteness with which the authors have entered into the details respecting them. Very few substances indeed, of this nature, found in the vegetable kingdom, have not been the subject of investigations leading to practical results for medical science. Those substances, on the other hand, which, although occurring in the vegetable kingdom, are yet much more frequently obtained from animals, or from inorganic materials, are not treated with the same detail. This is especially the case with the so-called fatty acids, as stearic, and in particular with acetic acid, a full account of which would not be looked for in a treatise on vegetable drugs. A difficulty was presented by the arrangement described above, in the case of those substances which occur in more than one family of plants. The alkaloids are in each case described under that order where they are met with most abundantly, or under that in which they were first discovered. With acids and neutral substances this plan could not be followed, and a certain number, as cellulose, starch, and glucose, are classified as bodies of general distribution, while others are discussed under one particular order, to which they more properly belong, with references from others where they also occur. Inulin, for instance, is placed under *Compositæ* (Synantheren), the authors considering that the older view of Mulder, that this substance is generally distributed, has been disposed of by the more recent investigations of Dragendorff and Prantl, and that, with the exception of *Campanula rapunculoides*, it is found nowhere except in the above-named family. Inosite again, though discovered by Marmé in several families, is yet placed under *Papilionaceæ*, from having been first found in *Phaseolus vulgaris*. Caproic and capric acids, on the other hand, are placed among the generally distributed substances, although at present found in only single families, from the strong probability that further researches will lead to their discovery in many others also. Pelasgonic, myristic, and lauric acids are considered as belonging properly to the orders of plants from which they respectively take their names. Avenin and conglutin are treated as dependants of legumin, with which they are apparently identical. The work being intended as a repertorium of facts rather than as an introduction to theories, the so-called rational formulæ of the substances are avoided in the headings, and are only referred to when treating of the composition of the more important. In by far the majority of instances, nothing but the empirical formula is given. The authors consider that as the real constitution of such well-known substances as alcohol, ether, and acetic acid, is still the subject of so much controversy, it is desirable, in a work of this kind, not to enter on so debatable a field in the case of the far more complicated compounds of which the work mainly treats. The sketch we have given will show that Husemann's 'Pflanzenstoffe' is indispenable to all who wish to make themselves acquainted with the most recent investigations in the regions of materia medica.

Obituary.

JOHN SAVORY, ESQ.

We regret to have to record the death on the 3rd instant of a gentleman who took an active part in the formation of the Pharmaceutical Society of Great Britain, and whose name stands third on the list of its presidents.

Mr. John Savory, born in 1800, was early apprenticed to his uncle as an apothecary. After a residence in Paris, where he studied pharmacy, and practised the then new art of cupping (which he had previously acquired under the celebrated Mr. Minors), he passed the examination of the Society of Apothecaries, but relinquishing any idea of practising, he became a partner in the firm of Savory and Moore. Mr. Savory was associated with Messrs. Wm. Allen, Jacob Bell, Morson, Payne, and other well-known pharmaceutists, in the foundation of the Pharmaceutical Society. For many years he took a very active part in its affairs, holding the office of president from the years 1844 to 1848 inclusive. Upon the passing of the Pharmacy Act, in 1852, he was compelled, as a member of the Society of Apothecaries, to break off this long connection, but he always retained a lively interest in the Society's welfare. He was a great advocate for the passing of the law making examination compulsory on all who engaged in the business of a chemist and druggist, believing it would tend to raise them to a higher social position.

Mr. Savory was a business man of the old school. Always active and industrious himself, he insisted that all that was done by those in his employ should be done well. He was fond of relating his own youthful experiences of assistants' life, and comparing them with the more luxurious manners and customs of modern days, not always to the advantage of those of the present day.

He had for the last three or four years retired from any very active part in the business with which he had been so long and honourably connected. Until latterly he was a hale man, but within the last twelvemonth a disease of an insidious character crept on him, and he gradually sank and died at Frant, in Sussex, in the 72nd year of his age.

In 1842, Mr. Savory read a paper on the Preparation of Syrups and Oxymels at an evening meeting of the Pharmaceutical Society, and he also furnished communications to this Journal on Extractum Cannabis Indicæ, Kousso, etc.

BOOKS RECEIVED.

THE SKIM-MILK TREATMENT OF DIABETES AND BRIGHT'S DISEASE, with Clinical Observations on the Symptoms and Pathology of these Affections. By ARTHUR SCOTT DONKIN, M.D. London: Longmans. 1871. From the Publishers.

TRANSACTIONS OF THE CLINICAL SOCIETY OF LONDON. Vol. IV. London: Longmans. 1871. From the Society.

The following journals have been received:—The 'British Medical Journal,' Oct. 7; the 'Medical Times and Gazette,' Oct. 7; the 'Lancet,' Oct. 7; the 'Medical Press and Circular,' Oct. 11; 'Nature,' Oct. 5; the 'Chemical News,' Oct. 7; 'English Mechanic,' Oct. 6; 'Gardeners' Chronicle,' Oct. 7; the 'Grocer,' Oct. 7; the 'Journal of the Society of Arts,' Oct. 7; the 'Brewers' Guardian,' Oct. 1; the 'Practitioner' for October; 'Mid-weekly Hampshire Independent,' Oct. 11.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. J. H. Wilson, Mr. Bienvenu, Mr. D. B. Hanbury, Mr. J. Robbins, Mr. Griffith, Mr. H. Deane, J. C. K., W. B., T. B., "Sigma."

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

THE CHIPPENHAM CASE.

Sir,—After the "withering" remarks of Dr. Fox upon my letter, published in your Journal a fortnight since, in reference to the above case, allow me, in justice to myself, to say how gratified I feel at so eminent an authority as Dr. Squire boldly and ably coming forward to endorse my views as to the "terrible" strength of the "solution," about which much correspondence has taken place. In my opinion, Dr. Squire deserves the thanks of our profession for the candid acknowledgment he makes of the necessity for our supervision of all prescriptions entrusted to us. This at once negatives Dr. Fox's "usurping" theory, upon which many "eminent" in the medical profession have a habit of venting their indignation unjustly.

October 9th, 1871. M. P. S.

Sir,—One final word on the subject of bichloride of mercury in ringworm. Your correspondent "*Thirty Years M. P. S.*" must forgive me for saying that his remarks are wholly irrelevant. He introduces an entirely new matter when he discusses the propriety of a pharmaceutist taking steps to rectify mistakes in prescriptions, and talks about internal remedies. I can only say that I shall be very much obliged to any pharmaceutist who may save me from the consequences of an oversight or inadvertence in any of my written prescriptions. I entirely repudiate holding the doctrine that a chemist is "to *dispense* but not *opine*." The real point involved, however, in the Chippenham case is the use of a *local* remedy which *is never written* in prescriptions, but is used only *by the medical man himself*. I never wrote a prescription, as far as I know, for the remedy; never certainly gave it to a patient, and no patient of mine ever took it to a chemist to be compounded. The remedy is used by the practitioner himself, and he alone; and therefore I naturally felt indignant at "*M. P. S.*" in his telling me that no chemist's assistant of six months' standing would dream of using a remedy so "outrageously strong," and so on, which was as much as saying that Dr. Meeres was either criminally reckless or utterly ignorant. But why, Sir, do your correspondents call the bichloride remedy in question a *lotion?* I have classed it in my work with "*vesicating parasiticides,*" in a separate group, distinct from "*milder parasiticides for ordinary use,*" with the very purpose of preventing it being considered "a lotion" or a simple application.

Again, your correspondents seem to be entirely unaware of the fact, that the very object of using so strong a solution of bichloride is to prevent absorption by inducing rapid and free coagulation of the albuminous fluids of the skin, by quickly *tanning* the skin in fact. TILBURY FOX.

PROVINCIAL EDUCATION.

Sir,—May I ask you to give publicity to the following announcement, extracted from the official statement of "Results of the Examinations of Science Schools and Classes, May, 1871"?—

"LIST OF QUEEN'S MEDALLISTS.

Subject—Vegetable Anatomy and Physiology.

Name.	Age.	Occupation.	School.	Teacher.	Medal.
Arthur N. Little .	16	Chemist	Bristol .	Leipner, A. .	Gold Medal.
Charles H. Cuming.	22	Chemist	Plymouth	Balkwill, F. P.	Silver Medal.
Subject—Systematic and Economic Botany.					
Arthur Northcroft	18	Chemist	Plymouth	Balkwill, F. P.	Silver Medal.
Subject—Animal Physiology.					
William Davis . .	17	Chemist	Torquay .	Viccars, T. . .	Silver Medal."

In order that your readers may correctly estimate the honours gained by these gentlemen, I may state that the competition for these medals is amongst the Science Class-students of the whole kingdom, and that although many prizes of books are distributed at these examinations, medals only to the number of one gold, one silver and two bronze in each subject are offered.

It can scarcely be necessary to point with any more elaboration to the advantage to provincial schools of pharmacy of alliance with the science class system. G. F. SCHACHT.

Clifton, October 7th, 1871.

DESGOFFE'S PATENT HYDRAULIC PRESSES.

Sir,—Will you permit us to point out a typographical error in the description of our "Desgoffe's patent hydraulic press," which appeared in the notes of the meeting of the Pharmaceutical Society (PHARMACEUTICAL JOURNAL, October 7, 1871). The smaller ram of the press is described as $13\frac{1}{4}$ inches in diameter, instead of $1\frac{3}{4}$ inches. It will be evident the power of the press depends on the lower ram, which is forced into the chamber, being smaller than the main ram which is forced out, the force being in proportion to the relative areas of these rams.

This leads us to mention another and much more important error, for which, we regret to say, the circulars distributed by ourselves at the meeting are responsible. By some mistake the power of the press has been there stated as 6 tons; whereas it will be easily seen that a pressure of three times that figure may easily be obtained; as below.

The circumference of the circle described by the handles = 50 inches. The thread of the screw, which forces the smaller ram inwards, is 5 to the inch.

The force with which the smaller ram is forced inwards is, therefore, $50 \times 5 = 250$ times the power applied to the lever.

Owing to the difference between the areas of the two rams being rather more than 4 : 1, this power will be rather more than quadrupled in its transmission to the work; making it equal to fully 1000 times that which is applied to the lever.

Now for such work as this, which is intermittent, and so arranged that a man can put out all his strength in one effort at the end of the pressure, we may reckon that the pressure applied to the lever will not be less than 50 lb.

Multiply 50 lb. × 1000
= 50,000 lb. = over 22 tons.

From this figure a certain amount must of course be deducted for friction; but the net result will show that this little press, in spite of its very low price, will accomplish all and more than all that will be required for extracting tinctures.

We believe, therefore, that this machine answers all the objections brought forward by Mr. Umney in his letter on page 290 of the same number of your Journal, as to the "too large" size, "excessive cost," and altogether "extra outlay" required for the adoption of hydraulic instead of simple screw pressure.

HAYWARD TYLER AND CO.

IMPROVED TINCTURE PRESS.

Sir,—I regret that the letter of *S. D.*, of Bow (PHARM. JOURN., September 16) has escaped my notice. With an apology for my neglect, I now reply to his queries.

1. If he will refer to my paper, he will find, the press described as being light and portable. There is no difficulty in raising it, cylinder and all, and pouring off the tincture from time to time into any suitable vessel or the filtering-funnel, the basin being spouted for the purpose.

2. The cylinder could be made by any tin-plate worker; if for a small press I think strong block-tin would do; but it should be joined by rivets, solder not being strong enough.

I cannot agree with Mr. Umney that the position in which the press is worked is unfavourable for muscular force, or that it should be compared either to pulling an oar or working a crank; for as both these labours are continuous, the person would soon become exhausted if he applied his full strength. Now, turning the screw of a press is very different; the labour being at short intervals, and the two arms of the lever grasped by each hand in opposition to the other, in my opinion, is rather favourable to the development of muscular power, although inferior to what it might be if the press were fixed and the lever vertical; in this position the power could be applied with greater ease, but would never exceed the actual weight of the individual. Now we know that many a person has strength enough to raise a weight much greater than his own body, so I think that my estimate of 100 lb.* represents a fair average of the force applied towards the end of the process, and that Mr. Umney greatly underrates it. As for my total estimate of the pressure obtained, as I before stated, it is somewhat theoretical, practically it is much less, a large deduction having to be allowed for counteracting influences, especially friction; hence the importance of any attempt to diminish this item, as in my press, the screws being but half an inch in diameter, and the pitch (or threads) only one-eighth, and these might be further reduced with advantage. I am pleased to find this important subject "ventilated," as it is the fashion to term it, but I did not write the paper for the purpose of raising an unprofitable discussion on the theoretical power of the screw-press, but rather in the hope of pointing how it might be improved. With this object I have endeavoured to utilize, what Mr. Umney with courteous sarcasm is pleased to designate, my "engineering skill," the result being the production of an implement which for its simplicity, convenience, and economy surpasses in efficiency anything I have yet seen.

I shall be happy to give any further information or answer queries either through your columns or direct, should any of your correspondents desire it. C. A. STAPLES.

THE DRUG TRADE IN CANADA.

Sir,—Allow me to answer the inquiries of your correspondent "Jateorrhiza" respecting the drug trade in Canada.

As to assistants, there is not any demand for their services beyond what the country can supply, and they are paid about the same as here in England. In Hamilton I received at the rate of 400 dollars per annum, out of which I paid four dollars a week for board and lodging (the dollar being equal to 4*s.* 2*d.* English).

The towns are well supplied with druggists, and I am of opinion that there is not any chance for a new-comer; but I was informed that there were chances for opening drug-stores in many of the rising villages in the Ontario district.

As the Canadian druggists deal in oils, paints, varnishes, and all kinds of paint-brushes, I should recommend a person going out with sufficient capital to start on his own account, to get a few months' experience in a good oil and colour shop in England before starting.

The Pharmacopœias in use were the British and the United States; but, as the Canadian Pharmacy Act has passed recently, there is probably a recognized Pharmacopœia. But perhaps, Sir, you can answer this question, as well as to whether English qualifications are allowed under the Canadian Act, of which I know nothing whatever, as it became law after I left that country.

Respecting the expense of starting a new concern, and the choice of a locality, I should refer "Jateorrhiza" to a respectable wholesale house on the spot for information—Elliott and Co., Toronto, or Wyner and Co., Hamilton.

In conclusion, it must be understood that I do not take upon myself the serious responsibility of advising any man to leave home and friends and start in a foreign land (which advice is too often thoughtlessly given), but only wish to answer inquiries made. W. B.

October 9th, 1871.

"*Scrutator.*"—We would recommend you to apply to some of the wine doctors who are to be found in the neighbourhood of the docks.

A. Shillcock.—We would suggest that you should apply to the persons in whose hands you think the remedy lies, and see what influence they could be brought to exercise.

J. R. Summers.—The matter referred seems to lie somewhat outside strict pharmaceutical practice.

"*Scribo.*"—You will find information as to the preparation of pepsine in PHARM. JOURN. 1st Ser. XVI. 472; 2nd Ser. VII. 112; 3rd Ser. I. 666; and Wood and Bache's 'United States Dispensatory,' 12th edit. p. 1091.

* In 'Practical Pharmacy' (Mohr and Redwood, p. 107) a compound screw-press is described, the *theoretical* power being 960,000 lb. (*i.e. over* 400 *tons!*); the calculation is based on the lever being moved by a force equal to 100 lb. I take this as a moderate estimate of strength, and believe it is often greatly exceeded.—C. A. S.

CHINESE PEPPERMINT OIL.

BY PROFESSOR FLÜCKIGER.

According to a notice contained in the *American Journal of Pharmacy*, May 1871, p. 223,* the Chinese, when suffering with facial neuralgia, use oil of peppermint, which they lightly apply with a camel-hair pencil. This application has now found its way to the opposite shore of the Pacific, where the immigration of Chinese people is very considerable. The American journal, indeed, states that Chinese pharmaceutists in San Francisco, as well as in New York, sell the said remedy for neuralgia, and that it has already gained some repute. The oil for this purpose is put up in small phials containing about half a drachm.

I had the opportunity, some weeks ago, of a conversation with a Swiss merchant, coming from San Francisco, who not only corroborated the above information, but showed me a phial containing the "Chinese medicine," which he had bought there himself in a Chinese pharmaceutical shop. The owner of the phial had frequently used it, and spoke in high terms of the good effects of the oil. The phial contained, I think, even less than half a drachm (price one dollar!), and was labelled, *Fook Chang Yong*, wholesale and retail druggist and chemist, 744, Sacramento Street, Corner Dupont, San Francisco.

I was suspicious enough to suppose the oil to be common peppermint oil of American or English origin, procured perhaps by the Chinese in San Francisco, although the said merchant firmly believed, for good reasons as he thought, it was directly imported from China.

Having pointed out the magnificent fluorescence which nitric acid imparts to peppermint oil,† I found that the above Chinese oil partakes not at all of this reaction; it is not coloured by nitric acid (1·20 sp. gr.), even when gently warmed with it.

A few drops of the oil exposed for some hours only on a glass slide yielded abundantly crystals of a camphor, reminding me in every respect of the solid *Japanese peppermint oil*, which during the past few years has been met with in European trade.

In both the above respects the Chinese peppermint oil is consequently different, at least to most of the specimens of European and American oil at my command, although it has the same agreeable flavour. Does it, that is to say its solid part, which appears to be prevailing, agree with the Japanese drug? I have ascertained that the latter is not altered by the treatment with nitric acid; it may therefore very likely be identical with the crystallizable part of Chinese oil. I have also been informed by the said Swiss gentleman that the "Chinese medicine" in cold weather solidifies even in California.

I should be happy if my fragmentary observations could induce some resident in China or Japan to devote some investigation to the mother-plant of the Eastern oils under notice, and to the production of the latter. Is the solid Japanese oil obtained by means of cooling from a liquid similar to the Chinese oil? Chinese oil is said to be distilled at Canton.‡

As to the former I beg to remind that it has been shown by Oppenheim and by Gorup-Besanez* to agree with the formula $C_{10}H_{18} + H_2O$, and to possess the nature of an alcohol. This so-called *Menthol* appears to be identical with peppermint-camphor, which sometimes in cold separates from peppermint oil; their identity, however, is not quite satisfactorily proved. Camphor obtained from peppermint oil has been analysed by Dumas, by Blanchet and Sell, and also by Walter.† Its percentage composition is the same as that of menthol.

VESICATING INSECTS.

BY M. C. COOKE, M.A.

(*Continued from page 262.*)

SPANISH FLY, *Lytta vesicatoria*, Fabr.; bright glossy brass-green or bluish, glabrous, beneath more glossy with a few hairs; breast densely pubescent, finely punctured; head and thorax with a longitudinal channel; elytra with two slightly raised lines; tarsi violaceous; antennæ black, with the basal joint brassy.—Pereira, Mat. Med. ii. p. 742, f. 117; Steph. Med. Zool. t. 26, f. 2; Brandt and Ratzeb. ii. t. xviii. f. 1–6; Muls. Vesicants, f. 14–18.—Form elongated, almost cylindrical; length 6–11 lines, breadth 1–2 lines; colour brass or copper-green; odour nauseous, unpleasant. Body covered with whitish-grey hairs, which are most numerous on the thorax. Head large, subcordate, with a longitudinal furrow along its top. Eyes lateral, dark brown. Thorax not larger than the head, narrowed at the base. Elytra 4–6 lines long, and from $\frac{3}{4}$–$1\frac{1}{2}$ lines broad; costa slightly margined. Wings ample, thin, membranous, veined, transparent, pale brown; tips folded. Legs stout, 4–6 lines long, the hinder ones longest; tibiæ clavate, in the female all terminated by two small moveable spurs, in the male the two hinder pairs of extremities alone have this arrangement, the anterior ones having but one spur; last joint of the tarsi with a pair of bifid claws. Abdomen soft, broadest in the female. In the female, near the anus, are two articulated caudal appendages (Pereira).

Native of the south of Europe. Found in France, Germany, Hungary, Russia, Siberia and England (rarely) on Oleaceous and Caprifoliaceous plants.

It is unnecessary to enter upon the details of this insect here, since it is included in all works on materia medica, and is the common officinal vesicant of Britain and other European countries.

Lytta Pallasii, Gebl., is very much like the common blistering-fly in colour and in size. It is a native of Siberia, and specimens may be sometimes picked out from amongst "Russian Cantharides." One distinguishing feature is, that the posterior tarsi of *L. Pallasii* are toothed, whilst those of *L. vesicatoria* are not.

L. phalerata, Walt., is a Turkish species closely allied to the foregoing, but, being a hairy insect, it would be easily detected if mixed with cantharides. We are not aware of its having been employed for that purpose; and, if so, it is probably a good vesicant itself, so that its mixture would not be fraudulent to the extent hereafter to be noted, in which case insects entirely inert have been used as adulterants.

Lucerne Blister Fly, *Lytta dubia*, Oliv.; black; head rufous, with a black line; thorax and elytra immaculate, margin of elytra ash-coloured.—Oliv. Ent. iii. t. 1. f. 7. *Cantharis rufidorsum*, Goeze, Ent. Beytr. 1777. *Meloe algiricus*, Sulz. Hist. Ins. t. 7. f. 12.

Found on the Lucerne and other plants in the South of France, Italy, the Levant and Southern Siberia.

About the size of *Lytta vesicatoria*. Antennæ black, filiform. Head rufous, the eyes and a superior longitudinal line black. Thorax black, with a longitudinal impressed line. Elytra flexible, black, with the lateral margin ash-coloured. Body black beneath and subtomentose. Feet black.

This is not the *Lytta dubia* of Fabricius, which is a Siberian insect, although it has been confounded therewith by some writers on vesicants, especially Moquin-Tandon, who cites it as a species employed in the South of France. It is unnecessary, in a communication like the present, to point out the technical distinctions between the two insects, confounded under one specific name. Goeze's name of *L. rufidorsum* is that under which the European species is best known to entomologists.

We are not aware of any other species that is collected in Europe for vesicatory purposes.

Asiatic Cantharides.

Syrian Blister Fly, *Lytta syriaca*, Fabr.; antennæ black; head black; thorax ferruginous, subrotund; elytra smooth, bluish-green; feet black.—Fabr. Sp. i. p. 329; Oliv. Ent. iii. t. i. f. 5. *Alosimus syriacus*, Mulsant, 'Vesicants,' p. 151. *Meloe syriacus*, Linn. Syst. Nat. p. 680.

Pubescent. Head black or greenish-black, ornamented in the middle of the forehead with a punctiform, yellowish-red spot; striped with a medial line on the vertex. Prothorax of a yellowish or testaceous russet, striped with a medial line and marked with a dimple between that line and each of the lateral edges, a little behind half of its length. Elytra of a greenish-blue or bluish-green; under side of the body of a greenish-blue or blackish-blue. Feet black or greenish-black.

Male.—First joint of the intermediate tarsi shorter than the second, hardly any longer than it is broad, compressed, and dilated underneath in an almost equal manner, separated underneath the tibiæ by a deep furrow. Last arch of the belly cut in or split as far as half its length.

Female.—First joint of the intermediate tarsi longer than broad, regular and not dilated. Last ventral arch entire or barely indented.

Moquin-Tandon cites this as an economic species, on the authority of Forskal. It is also quoted by Pereira.

Arabian Blister Fly, *Lytta segetum*, Fabr.—Fabr. Ent. Syst. i. 2. p. 84; Lucas, Expl. Alg. t. 34. f. 3.

Arabia, Sicily, Algeria.

Parallel. Upper side of the body bristling with a very short ash-coloured down; varying from a half golden green or blue to violet or violet-black. Head and prothorax marked with tolerably large and close dots, the former without any traces of a medial line. Antennæ black; first joint green, fourth and tenth joints a little longer than broad. Prothorax enlarged for two-fifths of its length, then parallel; truncated, and with a narrow border at the base, not so long as broad, generally marked with a dimple or furrow. Elytra at least once longer than they are broad together, almost semi-cylindrical. Tarsi blackish, the first joint of the posterior a little shorter than the two following together.

Male.—Last ventral arch cut in as far as one-half its length.

Female.—Last ventral arch entire, or scarcely at all indented.

This insect is also named by Moquin-Tandon as one of those employed as a vesicant.

(*To be continued.*)

THE PURIFICATION OF FATS AND SUETS.

The task that devolved upon the authorities of Paris during the late siege of that city by the Germans, of obtaining food for the many thousands who were cut off by the iron circle of their enemies from their usual sources of supply, was a difficult, and, as the event proved, an impossible one. Towards its accomplishment, however, great efforts were put forth by French *savans*, and for a time the whole current of scientific investigation was turned towards securing increased effectiveness in warlike weapons, the enforcement of the sanitary regulations best suited to the abnormal state of affairs, and the discovery and utilization of previously unknown or unused alimentary substances.

Among the many memoirs presented to the French Academy with the last-mentioned object, were some that treated of a subject not without interest to pharmacists,—the purification of fats and suets,—of which the following is a *résumé*.

M. A. Boillot communicated a method which he stated had yielded excellent results, and for which he claimed the merits of simplicity and moderate cost.* Two litres of lime-water is added to one kilometre of the fat or suet, mixed well together, and kept over the fire two or three hours. It is then left to cool, and, when it has become pasty and acquired a sufficient consistence, it is decanted, placed in flannel or linen, and submitted to an increasing pressure, when water and oleic acid, containing besides some solid fatty acids, from which it can readily be freed afterwards, passes through. The oily mass, after two or three days, acquires a whiteness which leaves nothing to be desired; and when freed from the little lime that it contains by treating it with water slightly acidulated with sulphuric acid, may be used for purposes of illumination. Fat thus prepared loses its bad odour, and acquires a remarkable hardness and whiteness;† and if run into water to which a small quantity of sulphuric or acetic acid, or vinegar, has been added, it will be thoroughly purified, and may be employed for all purposes to which the best fats are applied.

M. Dubrunfaut states‡ that the most tainted fat may be deprived of its characteristic odour by submitting it to the operation of frying; and that, after

* Comptes Rendus, lxxii. 36.

† The use of lime for the purpose of blanching lard has already been reported from America. There, however, it appears to be left as an impurity in the lard. See Pharm. Journ. 1st ser. Vol. I. p. 1043.

‡ Comptes Rendus, lxxii. 37.

being thus treated in a manner specified, it may be used for all culinary preparations, and even for pastry. For this fact he furnishes the following scientific explanation.

M. Dubrunfaut has practically ascertained, by laboratory and manufacturing experiments, that fish oil is radically deprived of its odorous principle by simply heating it to a high temperature (330° C.). He has also found that the fatty acids are volatilized in a current of steam at a temperature above 100° C., whilst the neutral fats remain perfectly fixed. Finally, he has found that the neutral fats comport themselves in a similar manner to the fatty acids under the influence of a current of steam, if they have previously been heated to a temperature of from 300° to 330° C.

The manner in which the purification is effected is by heating the fat in a frying-pan or other suitable utensil to a temperature of about 140° to 150° C., then cautiously sprinkling upon it small quantities of water. The vapour so caused traverses the fat, decomposes the neutral fatty substances,—which, as shown by M. Chevreul in the case of hircine, yield fatty acids,—the whole of the fatty acids are volatilized, and the purification is accomplished. These conditions, he says, unite all the elements which are favourable to the elimination of the volatile fatty acids, which are generally the material cause of the odours of fat substances. The product thus obtained is as perfectly purified as the finest lard.

M. Dubrunfaut had so much faith in the efficacy of this method of purification, that he called attention to the large quantity of candle tallow still in the city, and stated that by a modification of the process to suit the known constituents of the tallow, the whole of it might be so purified as to fit it for use in cooking various kinds of coarse flours, such as buckwheat flour, and thus secured for the purposes of alimentation. The same method might also, he stated, be applied to the large stock of colza oil.

In a second note presented to the Academy,* M. Dubrunfaut again called attention to the facility with which the large stocks of tallow and colza oil might be utilized for food, while the mineral oils would suffice for the purposes of lighting. On this occasion he pointed out the similarity of the origin of the kitchen fats and the tallow of commerce, and said that the absence from the kitchen fats of the repulsive odour of the tallow was due to the method of preparation. In the operation of roasting meat especially the conditions necessary for the purification of the fat—the high temperature and the superheated vapour—were realized in perfection. And although they were present in a less degree in the operation of boiling, still there was a real purification. This opinion is supported by the fact that tainted fat, undergoing ebullition in a melting-pot in the presence of salt water, is purified in proportion as the boiling is prolonged.

As the result of various experiments in which colza oil was treated according to M. Dubrunfaut's method, he reported that the oil lost its characteristic taste and odour, preserving only a slight savour that was not repulsive, and would not prevent its use in culinary operations.

MM. Wurtz and Willm reported† that they had found that when colza oil was submitted to a current of steam at a temperature of from 116° to 120° C., an odorous and acrid principle was carried off without sensibly saponifying the oil,—an inconvenience which followed the employment of steam too highly heated. Washing with a feeble warm solution of carbonate of soda takes away all traces of the fatty acids that may have been formed, or have pre-existed, in oil of bad quality; but the separation of the soap so formed presents some difficulties.*

M. Fua suggested† a modification of M. Dubrunfaut's method, which consisted in melting the fats at so high a temperature that the residue of the cellular and vascular tissues were thoroughly exhausted. He also expressed an opinion that these methods for the purification of fats were preferable to the introduction of either acids, alkalies, or other substances, as these foreign bodies had always to be removed afterwards.

* Comptes Rendus, lxxii. 57. † *Ibid.* lxxii. 57.

DIGITALIS.‡

BY J. MILNER FOTHERGILL, M.D.

The following particulars as to the composition, chemical characteristics, action, etc. of digitalis, are taken from the essay on "Digitalis: its Mode of Action and its Use," by Dr. J. Milner Fothergill, Senior Resident Medical Officer to the Public Dispensary, Leeds, for which that gentleman received the Hastings medal at the recent meeting of the British Medical Association at Plymouth.

Composition.—The leaves of digitalis have been subjected to repeated chemical examination, chiefly by foreign investigators. It has been found that there are various substances, which can be separated from one another, contained in them. The principal of these is digitaline. Indeed, by some it is considered the active principle; but of this Dr. Fothergill is not convinced; certainly it did not act on frogs so powerfully as the tincture of the leaves did. It is, however, frequently used. Digitaline is light yellow, inodorous, and crystallizes with difficulty, presenting the appearance of very imperfect crystals, if crystals at all, under a pretty high magnifying power (× 250). It does not contain nitrogen, nor does it neutralize acids. It is a principle, not an alkaloid. It is soluble in sulphuric acid, and also in hydrochloric acid. The solution in hydrochloric acid passes from yellow to a fine green. Homolle considered this reaction sufficiently delicate for medico-legal purposes. It is scarcely necessary to state that it is not generally accepted as being so. There are also digitalic acid, digitalin, digitalose, digitalide, of whose qualities we know nothing. There are also tannic acid, sugar, and a substance named pectin, chlorophyll and woody fibre.

Chemical Characteristics.—A dark precipitate (tanno-gallate of iron,—Pereira) is formed on the addition of sesquichloride of iron to the decoction, or to a mixture of the tincture and water. A solution of gelatine causes a scanty precipitate (tannate of gelatine). Tincture of

* Some idea of the importance of this subject to the Parisians under then existing circumstances may be inferred from the fact that the stock of colza oil in the reservoirs at Saint-Ouen and La Valette was estimated at from 12,000,000 to 13,000,000 kilograms. This enormous quantity had been accumulated by speculators who, anticipating a great demand for illuminating purposes, had obtained the oil from all the markets of Europe. It was the ordinary colza oil of commerce, prepared by warmth from the seeds of *Brassica Napus*, and had not undergone sulphuric purification which, while rendering it combustible, would have unfitted it for alimentation.

† Comptes Rendus, lxxii. 59.

‡ Abstracted from the Hastings Prize Essay, for 1870, published in the *British Medical Journal*, Nos. 548 to 553.

nut-galls merely causes a slight turbidity. There is no reason to suppose that any of the active principles are affected by these combinations; or that the drug is rendered inert by anything that we know. For a fuller account of its principles, the reader, if curious, can consult Pereira, or the thesis of Brunton.

Action on the Blood.—Magendie and Thackrah thought the addition of a decoction of digitalis interfered with the coagulation of the blood. Davy states that the addition of a large quantity of watery extract to blood gave it the consistence of paste. So far as was known to the author, no English observers have recently noticed anything peculiar in the blood of animals experimented upon. And in the large number of animals experimented on by him, there never was any appearance about the blood which made it different from any other blood. No scientific observations of any kind have yet been instituted as to the action of digitalis or any of its constituents on the blood, such as have been performed by Harley, Bernard, Fraser, and Crum Brown and Broadbent, on some other therapeutic agents, by which their action has been much elucidated.

On Plants.—Marcet and Brunton have separately tried the effects of digitalis on the haricot bean by watering the plant with an infusion, and found it to kill it by withering it up. The writer injected a strong infusion into the hollow stems of the ordinary bean without effect for days; in time, however, those so treated withered and died, contrasting with those not interfered with. Precisely the same results ensued from similar injections into the orange lily. A lettuce was frequently watered, in a dry season too, with a strong solution, without any perceptible injury to it either soon or late. Another was then dug up by the roots, and placed in a large basin containing a strong infusion of foxglove, and for a day or two grew amazingly; on the fourth day, it commenced to wither, and died in a day or two. The first effect of the drug was to improve the appearance of the plants to which it was administered; an impression to the same effect remains in the minds of friends who witnessed the experiments. Strong infusions were injected into the stem of the rasp, and into holes bored into a plum-tree without apparent effect.

On Invertebrata.—Snails, when touched with the tincture or strong infusion, took a contractile spasm, threw off a coating of mucus, and passed on apparently unaffected. Earth-worms, when placed in an infusion for a short time, did not appear incommoded. Wasps were not affected by it when applied to them.

On Fishes.—Minnows, when placed in an infusion of digitalis, a very weak one, for some minutes were not affected; then commenced a rapid movement of the gills, which lasted till death; they were also drawn to one side in dying. After death, the ventricle was found firmly contracted and glistening like a speck of gristle; and, on being examined under the microscope, no cavity was visible. The auricle was distended and vainly tried to drive any blood into the tightly contracted ventricle, the blood merely regurgitating into the venous sinus behind, and then flowing back again, from the venous distension relieving itself on the auricular diastole. On pricking the venous sinus so as to permit the escape of the contaminated blood, the auricle soon also became firmly contracted, and no cavity was perceptible under the microscope. The quickened action of the gills was probably due to the accumulation of carbonic acid in the blood, giving rise to an increased necessity for breathing, while the firmly contracted ventricle prevented the flow of blood to the branchiæ, and cut it off from oxygenation.

On Birds.—About half a drachm of strong infusion of digitalis was passed down the throats of two sparrows, some being spilled during the process. The animals soon became unable to move much, and gasped for breath most vigorously. The hen died first, and the cock died hard in about half an hour. On opening them immediately on death, the left ventricle in each was found firmly contracted; the lungs so congested as almost to be hepatized; the right ventricle full of blood. It was evident that the condition of the lungs and right ventricle was due to inability to drive the blood into the contracted left ventricle. The gorged condition of the lungs accounted for the gasping respiration observed. Side by side with them, ten drops of Fleming's tincture of aconite were administered to a third sparrow, who became convulsed, and died in about one minute and a half. In it, the lungs were pale, and the heart completely paralysed and distended, looking like a small Barcelona nut. The contrast between the two conditions was marked.

On Mammals.—Experiments have been made on the higher animals by Handfield Jones and Fuller, with similar effects as regards the state of the heart after death.

DISINFECTION.*

No. III.

The principle we have laid down—that we should not seek to remove impurities from the atmosphere by means of disinfectants, but that we should hinder the pollution of the atmosphere by applying disinfectants to surfaces which are befouling it—has never yet been sufficiently insisted upon, and is diametrically in opposition to much that passes current at the present day. History, too, records curious examples of the contrary procedure. In Dr. Angus Smith's book 'On Disinfectants,' we read that in 1780 Dr. Carmichael Smyth used nitrous fumes for disinfecting purposes in Winchester, and afterwards in the Fleet; and in the year 1802 was rewarded by Parliament with a vote of £5000 for his services.

The impracticability of dealing with the atmosphere by disinfectants can, notwithstanding, be very readily shown. Every chemist who calls to mind the extreme difficulty with which a comparatively small volume of gas is deprived of traces of impurities (for instance, the trace of carbonic acid naturally present in the atmosphere) will comprehend the immense practical difficulty of purifying the atmosphere of a dwelling-room by means of reagents which act by absorption; whilst the necessity, when dealing with the air of a dwelling-room, of not adding so much corrosive or stinking chemical to it as to make it unfit to breathe, is a complete bar to our attempting either the destruction of aerial poisons or the killing of aerial germs by the addition of powerful volatile chemicals to the atmosphere. When we add to the atmosphere of a room a sufficient proportion of an ordinary gaseous disinfectant to act on the atmospheric impurities, we render it unfit to breathe, and fit only to be sent up the chimney. All those mixtures for generating chlorine in dishes exposed in the sick-room, all the cloths soaked in liquid disinfectants and hung up in the room, are more or less futile for the purpose for which they are intended. In this general condemnation we do not include the use of disinfectant cloths to block up window or doorway communicating between the sick-chamber and the rest of the house. This we regard as quite legitimate, and as helping to isolate the patient.

In the selection of disinfectants for use in the sick-room, we should prefer such as are non-volatile and destitute of smell,—such, in fact, as will not themselves defile the air. For this reason, among others, bleaching powder and carbolic acid are not so suitable as some other disinfectants. Copperas and chloralum, possessing the requisite qualifications of being non-volatile and odourless, and being at the same time active disinfectants, are mentioned in the Oxford Disinfection Minute, which we have already referred to, and from which we quote the following:—

---

* Reprinted from the *Lancet*, Oct. 14, 1871.

"Waterclosets, privies, cesspools and drains can be disinfected by copperas (sulphate of iron). Carbolic acid can be used with advantage with, or after, but not without copperas. A certain quantity of disinfectant will disinfect only a certain quantity of foul matter; and disinfection is imperfect till all hot smell or alkaline reaction is abolished. For the disinfection of a cubic foot of filth, half a pound of copperas dissolved in a couple of quarts of soft water is sufficient. The daily addition by each individual using a privy or watercloset of two-thirds of an ounce of solid copperas to such privy, or one-third of a pint of the above solution to such watercloset, will keep it wholesome if any accumulation of filth which it may contain or communicate with has been previously disinfected according to the directions given above. Carbolic acid, which need not be chemically pure, can be used after the addition of copperas till the place smells strongly of it. It should be used in the fluid state, its combinations with lime and magnesia having an alkaline reaction, and being therefore unsuitable for the present purpose. It may be diluted by being shaken up with twenty times its volume of water, and if poured from a watering-pot with a rose-nozzle over the sides of a recently emptied privy or cesspool will do great good. Sawdust or sand strongly impregnated with carbolic acid may be used for this purpose. Chloralum (solution of chloride of aluminium of specific gravity 1160) will acidify ordinary sewage, and destroy its living organisms when added in the proportion of one part to forty. It may be expected, therefore, to act as a disinfectant. This cannot be said of chloride of lime. All waterclosets and privies should, when epidemics of cholera or typhoid may be expected, be disinfected whether they be offensive or not. It is well at such periods to avoid using any such conveniences which have not been disinfected, especially if, as at hotels and railway stations, they may have been used by persons from infected localities. All the conveniences mentioned need ventilating as much as living-rooms do."

The subordinate position of carbolic acid is noteworthy. If the experiments and researches that have been undertaken in regard to carbolic acid be reliable (*vide* Crace Calvert, in the *Chemical News* of Dec. 9th, 1870, and Dr. Ballard's remarks thereon in the same journal of Jan. 20th, 1871), then we must admit that undoubtedly carbolic and cresylic acids are about the most powerful of antiseptics; and there are few who will not admit that where carbolic acid can be used, it is the best for direct disinfection. Its odour is *the* objection against it, but still there is a very large number of cases in which the odour of the disinfectant proves no bar to its employment.

The minute also assigns a low rank as a disinfectant to chloride of lime; and here it will not be out of place to indicate the manner in which different disinfectants act on a mass of organic matter in incipient decomposition, such as fæces, urine, etc.

Copperas, chloralum and Burnett's solution (chloride of zinc) absorb the most offensive products of decomposition, which appear to be stinking alkaloids, and in so doing deodorize; they may also act as powerful antiseptics,—that is to say, arrest putrefaction, and so prevent the production afresh of products of decomposition; but more evidence is wanted on this point. Carbolic acid does not absorb the products of putrefaction which has already taken place, but it arrests putrefaction and so stops the further production of products of decomposition. Bleaching powder and Condy's fluid (alkaline permanganate) appear to oxidize the products of decomposition, but they have little power as antiseptics,—that is to say, they have little power of preventing the organic matter from continuing to putrefy. These latter, therefore, are not so economical as other disinfectants.

For use in cesspools and drains there is at present in the market a very cheap material, known as Cooper's salts, and consisting of a mixture of chlorides. It has considerable deodorizing power. It deserves a trial in privies and urinals, and indeed is known to answer in the latter.

Leaving the waterclosets and cesspools, and returning to the sick man's chamber, the first thing demanding attention is the night-stool or bed-pan, which should be charged either with a sufficient quanty of copperas or else chloralum. We think that most persons who have tried the two will be inclined to give the preference to the latter, from its superior cleanliness, and in the form of a dry powder sufficiently cheap to be used to cover the excreta it will be found very convenient. Charcoal or sand to cover up excrement and discharges of all kinds, and these moistened with copperas solution or solution of chloralum, will also answer. But carbolic acid and bleaching powder may be used in the sick chamber, on an emergency, when nothing better is at hand. Chloralum is very likely the best of the non-volatile disinfectants, but its superiority to Burnett's fluid, sulphate of iron, etc., can hardly be said to be as yet established.

The clothes worn by a patient ill with smallpox or cholera should afterwards be burnt, and, as far as possible, the bedding too. Failing this, they should be boiled for half an hour with soap and water, or else exposed to a dry heat of 250° F. In order to produce an appearance of cleanliness, bleaching powder may be used in the subsequent washing of the linen of patients suffering from infectious diseases; but it would be injudicious to rely on that substance as a disinfectant of the linen. Finally, it should be remembered that the surface of every solid which is for a length of time exposed in a sick-room inhabited by patients suffering from infectious diseases is liable to contract a taint, and will need disinfection. The surface of the patient may even be treated, and with great advantage to himself and everybody concerned. In most cases, as is now recognized, a bath will at least do no harm, and in cases of smallpox the addition of some convenient disinfectant to the bath has been found to comfort the patient.

THE PRINCIPLES OF GAS ILLUMINATION.

The important results which usually follow the investigation upon scientific principles of a subject in which previously practice had been founded almost entirely upon empirical rules, have often been urged as a reason for the increased spread of scientific teaching in this country. Doubtless many thousands of pounds are wasted yearly through inability to apply the knowledge of first principles to the common every-day things of life. A fresh instance of this has been furnished recently in the report to the Board of Trade on the construction of gas-burners with reference to the principles of gas-illumination.

At first it might appear that there is a certain lack of appropriateness in this subject for discussion in these columns. But questions continually arise in the development of the investigation which are akin to some of those of the pharmaceutical student's studies and might be expected to furnish points of interest to him.

To this may be added the perhaps somewhat more tangible and important fact to gas consumers, and therefore to pharmacists, that it is considered by the gas referees that half a million sterling—or one-fourth of the whole gas rental—is a moderate estimate of the amount that might be saved annually, in London alone, by the use of good burners. And lastly, the improvement of burners is also a measure of sanitary reform; as the required quantity of light being obtained from a smaller quantity of gas, not only is much unnecessary heat avoided, but the pernicious products of combustion discharged into the air (viz., carbonic acid gas, the sulphur impurities, etc.) are equally diminished.

In the section on the illuminating power of gas with which the report opens, the first question discussed is, Whether the illuminating power is affected by the quantity in which gas is burnt? or in other words, Is it more economical to use small burners or large ones? The doctrine that the light-giving power of gas varies with the quantity burnt, has been held by many eminent men, who have maintained that gas gives a larger proportion of light when burnt in large quantities. Mr. Farmer, of America, has put forth a proposition, known as the "Farmer Theorem," that the illuminating power increases in a geometrical ratio as the square of the gas consumed; *i. e.* that if two feet of gas give a light equal 4, three feet of the same gas will give a light equal to 9, four to 16, etc. This theorem, although accepted in America, has received no support in this country.

The first and most natural suggestion is, to inquire whether the observed variations in the illuminating power are not due, wholly or in part, to the mechanical apparatus employed for developing it. If two tons of identically the same coal do not, when burnt separately, give out the same amount of heat, is not the explanation to be sought in some difference in the mode of combustion? If two gallons of the same water, when weighed separately, do not show the same weight, must there not be some difference in the balances or in the details of weighing? In like manner, if four feet of gas do not give exactly two-thirds the amount of light which six feet of the same gas gives, is not the difference first to be looked for in the nature of the burners employed? Not to take into careful account the influence of the burners, when testing the illuminating power of gas, is as great an oversight as if, in weighing, one were to make no examination of the balances; or as if an engineer were to take no account of the boilers he employed, and then, finding that a ton of coal in some circumstances raised a greater proportion of steam than when half a ton was used, were to jump to the conclusion that the heat-giving power of coal became greater, relatively to the quantity consumed, when a ton was used than when half that quantity was employed.

What a boiler is to coal and the generation of steam, so is a burner to gas and the development of light. One ton of coal in a locomotive of the present day generates as much force as six tons did forty years ago, simply owing to the superior construction of the locomotive. In like manner, as regards the illuminating power of gas, there are good burners and bad ones. Moreover, as every scientifically-constructed boiler is devised specially for a given amount of coal, by the consumption of which the boiler developes its maximum of power relative to the quantity of fuel used; so every well-constructed burner is devised to consume a fixed quantity of gas. Indeed, for every burner, whether good or bad, there is a certain rate of consumption at which the burner does more justice to the illuminating power of the gas than at other rates, whether greater or less. To disregard these considerations, is to render experiments wholly useless and misleading.

As at the same rate of consumption, the light emitted by one burner may be much greater or much less than that of another, so also a burner which does most justice to the gas when the rate of consumption is five feet per hour, will, if the rate of consumption be either increased or diminished from that point, give out less light in proportion to the quantity of gas consumed.

Ignorance of these facts led early experimenters to the conclusion that because one Argand burning 4 feet an hour gave more light than two precisely similar Argands consuming 2 feet each, therefore gas gave more light when burned in the former quantity than in the latter. Upon similar grounds these experimenters might have maintained that because a ball fired out of a rifle with a charge of 3 drs. of gunpowder went further and had more penetrating force than two smaller balls fired out of two similar rifles each with 1½ drs. charge, therefore gunpowder had more explosive force, relative to its weight, when fired in the former quantity than in the latter. Every kind of burner is fitted to consume a special quantity of gas of a given quality, just as much as a rifle is specially adapted for a special ball and charge of powder.

In order to ascertain whether the illuminating power of gas increased according to the above theory a series of experiments was made, when it was found that instead of the gas giving more light as the rate of consumption increased, in every case there is a point beyond which the light decreases relatively to the proportion of gas consumed. This point lies always below, sometimes far below, the maximum of ordinary gas consumption, and varies considerably in different burners. Thus while one of the burners used in these experiments yielded its maximum proportion of light when the gas was burning at the rate of five feet an hour, with another burner that point was reached at less than two feet. It was found also that one burner gave at its best barely one-fifth of the light obtainable from the gas.

In order to account for the origin of the error the referees give some interesting facts. The chief means of obtaining the maximum of illuminating power from gas is to ensure an exactly adequate supply of air to the gas-flame. With Argands this point is easily found, for it immediately precedes the stage of combustion at which the flame smokes, *i. e.* when the air-supply becomes deficient, and a portion of the gas is not thoroughly consumed. Indeed, it may be stated as an absolute rule that *every burner gives its* OWN *maximum of light* (relative to the quantity of gas consumed) *when its flame is just upon the point of smoking.* With batwings and fishtails this point is not easily found, but with Argands (owing to the glass chimney which encloses them and regulates the air supply) it is always possible to increase the consumption of gas to such a point as will make the flame smoke: hence every burner of this kind can be used in a manner which will give the full illuminating power of the gas, *so far as that is dependent upon an adequate air-supply.* Now, as the common fault of Argands is that the gas issues under too great a pressure—*i. e.* with too great a velocity, thereby bringing the flame in contact with too much air—it follows that the worse the Argand, the better will it become when a large quantity of gas is burnt in it; for the air-supply, as regulated by the chimney, being nearly a fixed quantity, any excess in the air-supply can be neutralized by increasing the quantity of gas consumed. But with all Argands, whether good or bad, the larger the quantity of gas consumed in them (short of smoking), the greater will be the proportion of light which they give from the gas.

Other experiments tended to show that the illuminating power of gas remains the same, in whatever quantities the gas is consumed, provided that the right kind of burners be employed in the experiments. Every burner is fitted, and every scientifically-constructed burner is expressly devised, for a certain rate of consumption; and to use a 6-foot burner with three feet of gas would be as absurd as to use a 3-foot burner with six feet of gas.

It was found also in these experiments that there is a point in the rate of consumption below which the maximum of light is not obtained. It has been suggested that this was owing to a fixed quantity of gas being wasted, so far as illuminating power is concerned, it being consumed simply to produce heat in sufficient quantity to render the remainder of the gas incandescent and light-giving. This theory, however, was disproved; and the application of a rough apparatus for diminishing the supply of air, by which in one case the light was instantaneously increased nine-fold, showed that this too resulted from a supply of air unsuited to the amount of gas being used. This leads to the consideration of the air supply.

PHARMACEUTICAL EDUCATION IN THE PROVINCES.

THE recently published reports of transactions of local associations all agree in showing that attention is directed to the subject of education, but though, in some instances, there seems reason to believe satisfactory progress has been made, it is impossible to overlook the fact that, in a general way, there is a tendency to look upon special education as a necessity to be met as a matter of form and in the least troublesome way rather than as the chief basis of a successful career. The great aim on the part of students appears to be the acquisition of just enough knowledge of chemistry, materia medica, etc. to enable them to get through the Minor Examination; and in accordance with the usual relationship between supply and demand, the efforts of those who are endeavouring to provide means of education seem to be involuntarily restricted to the same object.

In making this comment on the attempts to establish systematic pharmaceutical education in the provinces, it is not by any means intended to disparage the efforts of those who are in various places exerting themselves to that end; for the tendency above referred to may almost be regarded as a natural consequence of the defective education given to boys while at school. How rarely it is the case that a lad at the time of passing from school to apprenticeship with a druggist has even the most elementary notions of chemistry, physics, or botany! Even in Latin he is frequently deficient. As a consequence such a lad is less able to profit by the practical experience he has while an apprentice, and what he does learn is but little understood. Subsequently, when he seeks to become an assistant, or to go into business for himself, the necessity of passing an examination is regarded as a disagreeable obstacle, and he has recourse to a system of cramming, to help him past it.

Considering the present distracted state of our middle-class educational methods, there is little doubt that some time must elapse before much improvement is manifest as regards the acquirements of those commencing a pharmaceutical career; anp until that is the case, we must be content at seeing apprentices and assistants studying subjects which in Germany or France schoolboys are familiar with.

It is true some schools are now including science among the subjects taught to boys, and in a few there are competent teachers; but that course is still only exceptional, and not unfrequently what is taught as science is merely legerdemain. For improvement in the scientific culture of the younger members of our calling, we would rather trust to the establishment by its senior members of a demand for higher qualifications than are generally to be met with. In this respect much still remains to be done. Looking through the advertisements for assistants, how rarely is it found that certificates of qualification are required! and when particulars are specified, they generally refer only to age, height, appearance, and such like.

THE RELATIONS OF "MEDICAL ETHICS" TO PHARMACY.

READILY and willingly to give advice and information upon every imaginable subject is generally understood to be an editorial function, and this understanding is fully relied upon by some correspondents. But we can easily sympathize with our contemporary the *Lancet*, when we read that it is one of its few "painful duties" frequently "to decide "on matters of professional conduct—to act as umpire "between brethren who, in the practice of their art, "may seem to have forgotten the principles which are "supposed to regulate the conduct of medical men "towards each other, and the public at large." Even the bliss of being "not without a certain authority upon the subject" must be tempered by such a sad necessity. Indeed, the extent of the evil,—and the probability, we presume, that our contemporary's columns will be required for something more interesting now that the dull season is over,—has moved its Editor to say a few words on the subject of Medical Ethics. Of course with the disputes of medical men among themselves pharmacists have no right or wish to intermeddle, but some of the editorial remarks are worthy of their consideration as the opinions of an "authority" on the matters discussed.

The first failing mentioned is the disregard by practitioners of the difference between a trade and a profession. We should not do justice to this paragraph without printing it entire. Here it is:—

"The essential distinction between a trade and a profession is in the nature of the service to be rendered. In the case of trade there is an exchange of wares for money; in the case of a profession, opinion, advice, or skilled judgment is the essential commodity to be exchanged. And some men cannot receive this pure professional idea of service. Perhaps it arises from a modest diffidence as to the value of anything they have to offer the public in the way of opinion or judgment, and so they supplement the real professional commodity with something more tangible. They deal in actual wares—such as tooth-brushes, soaps, perfumery, Tidman's sea-salt, vaccine lymph, cholera mixtures, etc. *Medicine is no longer a trade, even in drugs. Practitioners are under the necessity of supplying drugs to their patients because druggists have not yet discovered the art of dispensing prescriptions on practicable terms.* But this is a mere accommodation to their patients, and not of the essence of their services. A medical man should always, therefore, suspect himself when he finds wares of any kind entering largely into his idea of medical practice."

To the definition of the distinction between a trade and a profession we have nothing to object; but the tender forethought with which the "modest diffidence" of offending professional gentlemen is suggested,—the discrimination between excusable and inexcusable trade,—and the excuse furnished for the excusable,—are all worthy of the acknowledged high talents of the *Lancet* staff.

We are afraid that a suggestion that the low rate of fees charged for professional services by some practitioners arises from their inadequate sense of the value of medical service will be looked upon as a euphemism; but that which concerns us more particularly is the moral pointed.

"We have great respect for all earnest attempts to supply the working man with good medical attendance on terms which are practicable; but it is not to be done by private practitioners advertising their services as available for all and sundry *on terms which would scarcely pay a respectable druggist.*"

What inference are we to draw from this remarkable sentence? Does the prescribing by druggists become tolerable to the *Lancet* when the price paid is below a certain amount? And may we here find the *Lancet's* estimate of the relative positions of practitioners and pharmacists? Of course it is not credible that our contemporary would speak superciliously of chemists and druggists, but the mind insensibly reverts to the phrase, "And not as this publican."

As we have said before, we do not presume to interfere in the disputes of medical men. We are satisfied with ejaculating—

"Tantæne animis cœlestibus iræ?"

But does it not seem remarkable that educated gentlemen should be unable to decide for themselves what is right and proper, when such public discussion might lay them under the imputation of another weakness that the *Lancet* charges them with,—the love of publicity and advertisement? Might we commend to their notice the remark of a modern writer, that "to consume your own choler, as some chimneys consume their own smoke, is a negative, yet no slight virtue, nor one of the commonest in these times." And this especially as the Editor of the *Lancet*—who, on this occasion, has not been able to spare quite three columns—has half intimated that all the twigs of his editorial birch are not yet worn out.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

October 11th and 18th, 1871.

Present (11th)—Messrs. Allchin, Barnes, Bird, Carteighe, Cracknell, Davenport, Gale, Garle, Haselden, Ince, Linford and Southall.

Dr. Greenhow was also present, on behalf of the Privy Council.

(18th)—Messrs. Allchin, Barnes, Bird, Carteighe, Cracknell, Davenport, Edwards, Gale, Garle, Haselden, Ince, Linford and Southall.

Seven Candidates presented themselves for the Major Examination; *two* failed, *five* passed. Thirty-six presented themselves for the Minor Examination; *nineteen* failed, *seventeen* passed.

The following were declared duly qualified to be registered:—

MAJOR (as Pharmaceutical Chemists).

Maddock, William Thomas	London.
Marks, Benjamin	Plymouth.
Gill, Joseph William	Pendleton.
Woolley, Harold	Manchester.
Browne, Joseph Alleyne	London.

MINOR (as Chemists and Druggists).

*Jameson, William Edward	Bristol.
*Caswell, Thomas George	Dudley.
*Grayson, Charles	Bawtry.
*Redfern, John	Oxford.
Tamplin, Charles Edward	Kingston-on-Thames.
Jones, Moses	Swansea.
Hargreaves, Joseph	Liverpool.
Peel, Alfred	Manchester.
Fuller, John William	London.
Kennerley, William	Manchester.
Mumby, Charles John Everitt	Bury St. Edmund's.
Saunders, Thomas Samuel	Notting Hill.
Grace, Walter Abraham	Liverpool.
Morgan, Rhys Dafydd	Reading.
Marshall, Alfred	Hornsey.
Peake, Arthur	Stalybridge.
Gardner, James Richard	Devonport.

The above names are arranged in order of merit.

FIRST, OR PRELIMINARY EXAMINATION.

Two hundred and twenty-two candidates presented themselves for this Examination on the 2nd of October; eighty-two failed, the following one hundred and forty passed, and were declared to be duly qualified to be registered as—

APPRENTICES OR STUDENTS.

	Brown, Joseph	Croydon.
	Griffiths, Evan	Cardiff.
	Ingham, Thomas Whittaker	Rawtenstall.
Equal.	Hine, Alfred Leonard	Cheltenham.
Equal.	Longman, John Ham	Exeter.
	Chadwick, Thomas Edward	Bradford, Yorks.
	Bond, Frederick John	Tiverton.
Equal.	Crosby, John Briggs	Stamford.
Equal.	Newton, Francis Bourne	London.
	Evans, John	Cardigan.
	Cassels, David Malloch	Lanark.
	Brice, Francis	Leicester.
	Tomlinson, Eldred Edward	Whitehaven.
	Best, John William	Darlington.
Equal.	Jackson, Barnet Edward	Heywood.
Equal.	Mann, George Frederick	Wells, Norfolk.
Equal.	Power, Edward Thomas	Reading.

* Passed with honours.

	Warren, Francis William	Weston-super-mare.
	Bate, Arthur Macaulay	Northampton.
Equal.	Hamilton, Robert	York Town.
	Webber, Robert John	Woolwich.
Equal.	Hall, Robert	Hartlepool.
	Jones, Evan Jones	Lampeter.
	Sindall, George Edward	Knaresboro'.
	Watkins, William Powell	Blackwood.
Equal.	Eynon, Charles James	Leamington.
	Nettleship, Thomas William	Bawtry.
	Rayson, John Thomas	Swineshead.
	Attenburrow, Attewell	Hertford.
Equal.	James, Bryan	Coventry.
	Newton, George Harry	Ashton-und.-Lyne.
	Parkinson, Joseph	Huddersfield.
	Tipper, Jonathan Edward	Evesham.
Equal.	Boon, Nathaniel	Oakham.
	Harris, John	Pontardawe.
Equal.	Blacklock, John	Manchester.
	Goodall, Thomas Sorby	Derby.
	Radford, John Storer	Nottingham.
	Bales, William	Ipswich.
Equal.	Baxter, Thomas Abbott	Stamford.
	Beaven, George Alfred	Southampton.
	Douglas, John	Cockermouth.
	Hooper, James Tapscott	Launceston.
	Pinnell, Arthur	Broadstairs.
	Martin, William Lee	Derby.
Equal.	Morgan, David	Llandilo.
	Williams, Thomas	Welshpool.
	Francis, Rawson Parke	Diss.
	Pickup, William	Blackburn.
	Bishop, Charles Edward	Bristol.
Equal.	Barcham, Henry	Hackford-next-Reepham.
	Cattell, John Thomas	Coventry.
	Dixon, George Frederick	Crediton.
	Owen, George Benjamin	Sheffield.
	Howell, William	Cheltenham.
Equal.	Baxter, William James	Devonport.
	Davies, William	Trecynon.
	Elliott, William Thomas	Stowmarket.
	Lewis, John	Pontardawe.
	Stevens, James	Ripon.
Equal.	Borton, Thomas Bonner	Hull.
	Horrax, John	Keswick.
Equal.	Duncalf, Thomas Henry	Macclesfield.
	Hesk, Thos. Galland Charis	Whitby.
	Radford, George	Chesterfield.
Equal.	Campbell, Charles	Hull.
	Smithies, William Edward	Elland.
Equal.	Bishop, Edward Ernest	Bristol.
	Jones, Matthew Henry	London.
	Lister, Robert	Leeds.
Equal.	Croskell, William Joseph	Liverpool.
	Griffiths, John Moore	Birkenhead.
Equal.	Berry, Robert Innes	Aberdeen.
	Collis, John Tucker	Bristol.
	Moon, Murray James	Godalming.
Equal.	Findlay, James	London.
	Winter, Harry	Cambridge.
Equal.	Gordon, Frederick William	York.
	Jones, John Griffiths	Nottingham.
	Ward, John Septibo	Stamford.
Equal.	Carr, Henry	Rochdale.
	Gregson, Thomas Halliwell	Ashbourne.
	Smailes, Francis William	Filey.
	Solomon, Charles Edwin	Penryn.
Equal.	Oldfield, Frank	Hawkhurst.
	Plant, John	London.
	Stratford, Alfred Joseph	Kilsby.
Equal.	Hockenhull, Philip Hall	Macclesfield.
	March, Richard	Stamford.
	Marks, Frederick Comerford	Wantage.
Equal.	M'Cullock, William	Manchester.
	Payne, Henry	Cottingham.
	Unsworth, Walter	Bolton-le-Moors.
Equal.	Clare, Thomas	Cheltenham.
	Hindle, William	Lowestoft.
	M'Lean, Kenneth	London.
	Rhodes, John Mitchell	Sheffield.
Equal.	Barber, Walter Masterman	York.
	Maud, William Robert	York.
Equal.	Cardell, Richard Taylor	Bodmin.
	Richardson, Edward	Dresden, Staffs.
	Phillips, Charles Lloyd	Tredegar.
	Ward, William Edwin	Nottingham.
	Davies, George Edward	London.
Equal.	Linton, William Tabram	Chichester.
	Taylor, Stephen John	Westbury, Wilts.
	Slater, Elias	Manchester.
Equal.	Cox, Joseph	Nottingham.
	Hayllar, James	Luton.
	Marrion, William	Shrewsbury.
Equal.	Coulson, Charles Edwin	Sudbury.
	Truscott, Lewis James	Looe.
	Owen, John Edward	London.
	Harris, Henry Brock	Bristol.
	Forsyth, Richard	South Shields.
Equal.	Dyson, Alfred	Brighouse.
	White, John Thomas	Dudley.
Equal.	M'Gregor, Peter Gibb Duncan	Colpy Culsalmond.
	Smith, Thomas Henry	York.
	Thompson, Charles	Bedworth.
Equal.	Brouard, Ernest James	Guernsey.
	Empringham, George Edward	Beverley.
Equal.	Anderson, Henry	Guernsey.
	Bowker, William	Bolton.
	Harris, Evan William	Aberavon.
	Houghton, Robert William	Bermuda.
Equal.	Lupton, George Frederick	York.
	Mead, Charles John	Wimborne.
	Parsons, Charles Ernest	London.
Equal.	Coates, Samuel William	Ilkeston.
	Ferguson, William	London.
	Griffiths, Griffith	Barmouth.
	Hues, William Richard	Liverpool.
	Maggs, Frederick Richard	Yeovil.
	Newbould, John Benson	Liverpool.
	Redman, Joseph	Rochester.
	Reeve, Thomas Lewis	Hastings.
	Wood, James	Devonport.
	Young, Horatio Thos. Barmby	Hull.
	Jones, Edward Bevan	St. Neots.

Certificates of examination of the under-mentioned were received in lieu of the Society's Preliminary Examination:—

Cooper, Frederick Ashley	Cockermouth.
Cortis, Arthur Brownhill	Worthing.
Hepworth, Frederick James	Saltburn-by-the-Sea
Hutchin, William F. W.	Maidstone.
Moss, Albert	Ilkeston.
Redfern, John	Oxford.
Reeks, John	Southampton.

The following is a list of towns in which examinations were held, with the number of candidates annexed:—

Aberdare	3	Cambridge	2
Aberdeen	5	Cardiff	2
Abingdon	2	Cardigan	3
Ashby-de-la-Zouch	1	Carmarthen	3
Ashton-under-Lyne	1	Carnarvon	1
Barnstaple	1	Cheltenham	3
Basingstoke	1	Chester	3
Birkenhead	1	Chesterfield	1
Birmingham	2	Chichester	1
Blackburn	2	Cockermouth	3
Bolton	1	Coventry	3
Boston	1	Darlington	1
Bradford	2	Derby	4
Bridlington	1	Diss	1
Bristol	4	Dorking	1

Dudley	1
Durham	1
Evesham	1
Exeter	2
Falmouth	1
Goole	1
Grantham	1
Guernsey	2
Hartlepool	1
Haverfordwest	1
Hertford	2
Hitchin	1
Huddersfield	2
Hull	4
Huntingdon	1
Ipswich	2
Ironbridge	1
Knaresborough	1
Lanark	1
Launceston	2
Leeds	1
Leicester	3
Liskeard	1
Liverpool	4
London	30
Macclesfield	3
Manchester	9
Merthyr Tydfil	1
Middlesborough	1
Neath	1
Newcastle-on-Tyne	1
Newport (Mon.)	1
Norwich	2
Northampton	1
Nottingham	4
Oxford	1
Peterborough	4
Plymouth	2
Poole	2
Preston	1
Ramsgate	1
Reading	1
Ripon	2
Rochdale	3
Rochester	2
Rugby	1
St. Alban's	1
St. Austell	1
Sheffield	2
Southampton	2
South Shields	1
Spalding	1
Stamford	6
Stockport	2
Stoke-on-Trent	1
Sunderland	2
Swansea	5
Taunton	4
Tenterden	1
Tiverton	1
Truro	1
Walsall	1
Wakefield	2
Warwick	1
Welshpool	2
Westbury	1
Weston-super-mare	1
Whitby	2
Wolverhampton	2
Yarmouth	2
York	5

The questions for examination were as follows :—

Time allowed: Three Hours.

LATIN.

Translate into English two or more of the following sentences:—

1. Quum ea ita sint, tamen, si obsides ab iis sibi dentur, uti ea, quæ polliceantur, facturos intelligat, et si Æduis de injuriis, quas ipsis sociisque eorum intulerint, item si Allobrogibus satisfaciant, sese cum iis pacem esse facturum.

2. Biduo post, Ariovistus ad Cæsarem legatos mittit, velle se de his rebus, quæ inter eos agi cœptæ, neque perfectæ essent, agere cum eo: uti aut iterum colloquio diem constitueret; aut si id minùs vellet, ex suis legatis aliquem ad se mitteret.

3. Coque Coccum in Aquâ per quartam horæ partem in vase operto, subinde movens, tum cola, et perfice sicut de Syrupo Althææ præceptum est.

4. Ex his fiat haustus, summo mane deglutiendus. Repetatur idem tertio quoque die.

5. Give the genitive endings, singular number, of the five declensions.

6. How are noun-adjectives of three articles declined? Decline one.

7. State to which conjugation each of the following verbs belongs:—*mitto, repeto, moveo, constituo.*

8. What case do the following prepositions take after them?—*absque, cum, pro, sine.* Illustrate by examples.

9. What cases do gerunds and supines govern? Furnish examples.

ARITHMETIC.

10. A. was born 34 years after B.; how old was B. when A. was 17? and how old will A. be when B. is 70?

11. The planet Mercury revolves round the sun in 88 days; how many revolutions will it perform in 17 years and 219 days, reckoning 365 days to the year?

12. Reduce $\frac{4}{5}$ of a cwt. to its proper quantity.

13. From $5\frac{2}{3}$ take $\frac{9}{10}$.

14. Add $3275\cdot + 27\cdot514 + 1\cdot005 + 725\cdot + 7\cdot32$.

ENGLISH.

15. Of what does syntax treat?

16. Explain the difference between simple and compound sentences, and furnish examples.

17. Name several nouns which are irregular in the formation of their plural.

18. Correct the following:—Flattery cannot hurt none, but those who it is agreeable to.

19. Parse the following:—Industry is the road to wealth, and virtue to happiness.

20. Write from fifteen to twenty-five lines upon *one* only of the following subjects:—

A. The force of example.
B. True courage.
C. The power of hope.

Provincial Transactions.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The opening Meeting of the third winter session of this Association was held on Wednesday evening, Oct. 11th, in the Rooms, Music Hall; and the following inaugural Address was delivered by the President, Mr. J. B. Dobb:—

Gentlemen,—There was a time, at no distant date, when the chemist and druggist was treated and considered as a very mysterious man, who knew something of herbs, drugs, chemicals, ointments and plasters; who could tell you something of the firmament as well as of the earth. There were instances of his being an astrologer, a ruler of the planets, a curer of wounds and of all the ailments to which poor man is liable. The chemist and druggist was more of a general practitioner than he is now. The time has been when he was the Esculapius of the town and village; the apothecary, surgeon and physician; the thoughtful manufacturer of pills and boluses, as well as the dealer in drugs. He was often trusted and confided in by most of the people; he was a thorough empiric, having experience only to guide him. There were no laws to prevent him healing the sick and visiting his patients. He was the popular leech; he supplanted the barber with his lancet and his blood-stained pole,—that pole, emblem of blood and linen bandage, stuck out of the front of the shaving shop, how art thou fallen! Thou hast given way to the gilded pestle and mortar over the door of the chemist's shop, and to those quaint-looking bottles in his window. What beautiful-looking liquids they contain!—blue, red, green, yellow and all the colours of the rainbow; surely it must be medicine! Look at the singular golden marks upon those turnip-shaped globes: it must be the name of the stuff in them. What an awfully wise man the proprietor of that shop must be! The educated man looks upon the last relic of the old druggists—the big-bellied globes, with the Egyptian or mongrel hieroglyphics in gilt—with a feeling of curiosity and sacredness, as things appertaining to physic and necromancy. Popularly, the chemist makes, or did make, wonderful profits; nothing less than $11\frac{1}{2}d.$ in the shilling would satisfy the keen faith of the general public. The profit of $11\frac{1}{2}d.$ in the shilling had a surprising effect in overflowing the business with apprentices (accompanied with good premiums also). The supply of chemists and druggists exceeded the demand of the public. This constant influx brought in competition; a living could not be made by the sale of physic; and the chemist was constrained to sell other goods—perfumery, etc., in large towns; paints, oils and colours, and all the odds and ends of domestic requirements in the country to eke out an existence. The time has been within the memory of the present chemists and druggists when most powders had to be ground, rubbed and thumped in a mortar by the strong and powerful arm of the druggist himself or his apprentice. Never shall I forget the hard work, the struggle I had with a nice bit of a mill, the size of a domestic coffee mill, for grinding pepper. Even the grinding of paints on a slab with a muller was all done by the chemist and druggist in the country. Let us be thankful that the colour manufacturer and the wholesale druggist have relieved the present race of chemists and druggists from all this drudgery, and that our young men will have more time at their disposal for cultivating their minds, and acquiring that scientific knowledge, not only for passing their examinations, but for upholding the honour and status that the trade is aspiring and panting for,—changing, I trust, the trade of a chemist and druggist into an honoured and scientific profession. Workmen labour less hours than formerly, so do clerks, manufacturers and merchants. There is a movement in the same direction amongst shopkeepers. Take the dispensing chemist in London and throughout the country; the hours are from eight in the morning until ten or eleven at night in London; in the country, eight to eight, nine or ten at night. These hours are too long. They have a most depressing effect, preventing energy in business and determination in study. I grant there is the danger in our early closing of our young men abusing these hours of liberty, devoting their time to pleasures and amusements (so liberally provided in all large towns, places literally used to entrap the young), instead of using these golden hours in study, and striving to fit themselves for their duties and the battle of life. Provided the hours taken from business were used and not abused by our young people, early closing would be indeed a blessing to all engaged in the trade. Every encouragement should be given to lessen the hours of labour. It should, in my opinion, be done gradually, to see if these leisure hours are properly used. Let us cultivate in our youths a tendency to come to our rooms. The time is drawing near when they will find out that it is a necessity for them so to do. Unless they avail themselves of the opportunity to acquire a knowledge of our specimens of drugs, the pharmaceutical preparations, and an acquaintance with our library in this room, there is every probability when they go to London for examination they will return plucked. A few examples of the simple-minded plucked ones would, I think, do a power of good to our cause,—contributing more to a good attendance at our rooms and our lectures and our classes than all the persuasive powers of the Council of this Association. There is one thing stands very much in the way of this early-closing movement. I allude to the custom and habit of putting up the shutters, but leaving the door of the shop on the latch. The gas burning bright inside is like an invitation to all passers-by that they can obtain what they require inside that establishment, though the shop is "supposed to be closed," and all the staff done work. This custom and habit is of long standing. Those who would close are thus prevented by their neighbours. They say, I will make no pretence of closing. When I put up the shutters I will close the door, and have done with the labours of the day. The medical faculty do not stop in, waiting for patients; the physician's hours are defined except for appointments. I do not see that the public require these late hours of business. I do not see that they even benefit us in a pecuniary sense. And I trust the time has arrived when we may gradually give them up, and find time to cultivate our minds and enjoy the blessings of life,—

> "Not always working, not always playing,
> Doing both, and enjoying both."

Most of you are acquainted with the early history and struggles of the Pharmaceutical Society. There also sprang up the Society of Chemists and Druggists, to prevent what they thought the monopolizing tendency of the old Society. These two Societies struggled, one for supremacy, the other for equality. Better counsels and better feelings alternately prevailed. They had felt each other's strength and power; each saw the other had some good properties; united they would be strong. Lord Elcho advised them to settle their differences; his advice was carried out, and we became an incorporated trade. From the passing of this Act commenced a new era in our history; take Sheffield as an example of the rest of the provinces. A local Association has been formed in connection with and attached to the Pharmaceutical Society of Great Britain, the object being the education of our members, and to enable them to rise to the standard of the Pharmaceutical Society. There is now a fair and open field for those who desire to enter the ranks of the profession of a pharmacist—a profession they cannot enter except by careful study, fitting themselves for responsible duties that will bring honour to the profession, and conduce to the interests of the public. Our trade has been maligned, and twitted with trenching upon the vocation of the medical man. Where do the quacking druggists come from?—the men who place a few coloured bottles in a shop-window as ostensible druggists, and who go out and visit patients, contesting the rounds with the medical faculty. Is it the young men who have served an apprenticeship to the trade?—is it the young men who have passed the examinations of the Pharmaceutical Society? My impression is it is not this class of men. I think you will find most of them come from the surgeries of the medical faculty—students who could not or had not the means of passing their medical examinations; who had been educated and drilled to visit patients. Stable-boys are sometimes taken into a surgery to assist; after a while the dispensing is entrusted to their care; when arrived at mature years, on the ground of wages or other circumstances, they are replaced by other youths. What becomes of these men? If they have got a smattering of the knowledge of medicine, such men have often commenced as chemists and druggists, visiting patients and administering such physic as they were accustomed to make up in their masters' surgery. It has often been proclaimed to the public through the medical journals that chemists and druggists more or less live upon quackery, and are a class whose privileges should be curtailed. When you see a druggist visiting patients, you will generally find he has acquired the habit and learned the rudiments of such a practice in a surgery. Who is responsible for such a state of affairs? I assert, the medical profession; they had educated the men for such a style of business, and it is a libel on the trade to charge us with that for which they themselves are principally liable. I advise our members on no account to poach on the domain of the medical faculty by leaving their shop to visit patients, but hold on to their right of prescribing behind the counter. You have as great a claim to that right as the medical faculty have to dispense their own medicines. When they are prepared to give up such a practice, then it will be time for the chemist and druggist to consider the propriety of giving up prescribing behind the counter. Let us be thankful that this practice of going out to visit patients will, to a great extent, become an experience of the past. I cannot imagine a man who has obtained his diploma as a pharmaceutical chemist, or as a chemist and druggist, adopting the practice of visiting. Should he do so, he would at once lose caste, and take a low standard in the scale of his profession. There is a bright and prosperous future open for apprentices and students who qualify themselves to pass the examinations of the Pharmaceutical Society. There cannot be that amount of huckstering competition that has been the rule hitherto. We, the old and middle-aged chemists, may not live to see our hopes realized; but we shall have this consciousness that we have fought to clear the way for our younger brethren. Provided no benefit accrues, which we cannot expect, the honour, the emoluments and the status in society occupied by you as scientific, educated chemists and druggists, will all be yours. Reap the advantage of our exertions, and we shall be satisfied, feeling that we have done our duty in striving to raise the position of the trade, and conferring a benefit upon society, by placing intelligent, educated men at their disposal for the compounding and dispensing of medicines. In the future I look for the explorers of nature's mysteries, those close reasoners and thinkers, the analytical chemists, to spring out from the men who obtain the distinction of pharmaceutical chemists by examination. In the future, what is now a trade, will, I believe, be split up into several trades: the hairdressers are fully capable of retailing perfumery, tooth-brushes and all the articles of the toilet; oil and colourmen can undertake the mixing and selling of paints, oils and colours; the grocers, of pickles and fish-sauces; and the drysalters, of chemicals and drugs used for manufacturing purposes; at the present time, all these articles, more or less, are dealt in by chemists and druggists.

During the last two years questions have arisen of great importance to the trade, and given great anxiety to your Council. I allude to the proposed compulsory poison clauses. At one of our special meetings the following resolution was passed:—"In the keeping and dispensing of poisons, the heavy responsibilities resting upon members of the trade tend to make them take the most careful precautionary measures to prevent accidents. And as every business is so varied and peculiar in its character and circumstances, each principal ought to remain at liberty to make such arrangements as will best suit his own peculiar case, and any definite legislation on the subject would be unwise, inconvenient and unnecessary."

Mr. Wilson and Mr. Hill were deputed to represent the Association at the Annual meeting of the Pharmaceutical Society, well and truly did they do their duty. Recently, when deputations were received by the Pharmaceutical Council on the compulsory poison clauses of the proposed Amended Pharmacy Act, Mr. Wilson and Mr. Preston went to London to express the feeling of the Association on that question. They had conferences with both our borough members and others; they worked hard. They were armed with the following resolution, passed at a special meeting of our Association in this room:—"That partial legislation on the subject of poisons is impolitic and unjust, and that any legislation that does not apply equally to surgeons, apothecaries, veterinary surgeons, hospitals and dispensaries, cannot be deemed satisfactory." These views were impressed on the minds of those members of Parliament and others with whom they came in contact, by Mr. Wilson and Mr. Preston; and I am justified in saying with very great success. The Bill was withdrawn. Let us maintain these principles, and act energetically when the time comes, as come it will. The subject is not closed or ended; show the same determination that you have done the last six months, and I do not fear the result.

In conclusion, I beg the young members, apprentices and associates will take an interest in these rooms. The museum, library and microscope are all at your service for study. I impress upon you the importance of a regular attendance upon the classes and lectures held here. The Council have found the principal means hitherto, and are working hard, to give you every opportunity for acquiring such a knowledge as will enable you to pass your examinations, and to join with credit the scientific profession of a pharmaceutical chemist. All this is of little service to the old chemists and druggists. The advantages are all your own; assist us by your subscription, with your personal interest in the work, and use your influence with your fellow-apprentices and assistants. Such attention on your part will amply compensate your Council for all their labours on your behalf.

The address was heard with great attention, and was frequently applauded.

A cordial and unanimous vote of thanks, proposed by Mr. Wilson, seconded by Mr. Radley, and supported by Messrs. Cocking and Preston, was then passed to the President, and other business having been transacted, the meeting terminated.

The following gentlemen were elected associates:—Messrs. Boulton, Corbett, Field, Holmes, G. M. Jones, H. D. Jones, and Mellor.

LIVERPOOL CHEMISTS' ASSOCIATION.

Twenty-Third Session, 1871–72.

Mr. Edward Davies, F.C.S., etc., President; Mr. Charles Jones, Vice-President; Mr. John Shaw, Treasurer. Council—Messrs. Abraham, Mason, Murphy, Redford, Sharp, Sumner, Symes, Tanner. Honorary Secretary—Mr. Joseph Hallawell, 10, College Lane.

The First General Meeting was held at the Royal Institution, on Thursday evening, the 12th instant. The President, Mr. E. Davies, F.C.S., in the chair.

The Minutes of the previous Meeting were read and signed. Messrs. E. Alfred Webb, James T. Armstrong, and J. Rigby were elected Members. Messrs. C. F. Pearson, W. A. Jones, and Arthur Anderson were elected Associates of the Association.

The Secretary announced the following donations received during the recess:—The Year-Book of Pharmacy, 1871,—The Register of Chemists and Druggists, 1871,—The Report of the Smithsonian Institution, Washington, U.S. 1869,—The Chicago Pharmacist,—The New York Druggists' Circular,—The Pharmaceutical Journal,—Proceedings of the Liverpool Naturalists' Field Club,—Proceedings of the Liverpool Architectural and Archæological Society.

The President read his opening address:—

Gentlemen,—In coming before you in the honourable position of your President, I feel that I can only look upon myself as an example of your willingness to reward work, earnest and faithful, however imperfect, which has been given to our common object, the improvement of practical chemistry. I trust that my elevation to the office will not cause any distrust in the minds of pharmacists in our Association, lest one great object of its existence should be neglected, by undue prominence being given to the scientific branches of chemical study, for I believe that no sure progress can be made, in this or any other department of science, unless theory and practice, the purely scientific and the purely business views go hand in hand. The mutual dependence of the scholar and the tradesman each day becomes more evident, and no feature of modern opinion is more striking than the prominence given to science training. There is, however, an erroneous idea in the mind of many that a special department of a science can be taught, and that one man may learn dyeing chemistry, another alkali-making chemistry, and another pharmaceutical chemistry. Now this, in my opinion, is a mistake, and having tried to work (to order) in this way, I find it no use. It might be possible thus to "cram" for an examination, but knowledge to guide a man in the unexpected difficulties of daily life must be built on a broader foundation. It is easier, too, to lay hold of, and to retain a principle than a mass of unconnected detail, and, for an example, he will more intelligently and more accurately test the quality of drugs, who in a regular course of study has mastered qualitative analysis, than he who has laboriously committed to memory every test given in the Pharmacopœia. I would therefore employ a portion of our time this evening in a defence of pure science, the study of chemistry, as if money value were a thing unknown, and the attainment of truth for truth's sake. And this need not, nay should not be inconsistent with a hearty acceptation of the realities of life, and a careful performance of its meanest details.

To look at the past. There was a time, and it is startlingly near to our own, when there was no science of chemistry, nothing but haphazard, uncomprehended experiment. This was the case in all its departments, but in medicine there was no attempt at system. Even when plants ceased to be gathered under fixed planetary influence, the cause of their specific influences was veiled by the impossibility of separating one definite substance from an organic, heterogeneous mass. But pure chemistry came to the rescue; and we owe to it the long list of vegetable alkalies, many vegetable acids, and we may hope that every drug will, in time, yield its active principle, to be administered in a small compass, and without nauseous accompaniments, which in many cases are useless.

In these researches there was at least some idea of immediate use, and a definite object was before the experimenter's mind; but, not bound by the actually existing, the chemist begins to create new compounds not found in nature, and which to many are the sheerest nonsense, waste of time and thought. Yet in medicine alone we owe to such men chloroform, chloral, carbolic acid, etc., now recognized as most valuable means of healing; and no doubt yearly additions will be made to the list. Apomorphia seems certain to win a place in our pharmacopœias, and Dr. Richardson is making experiments with bichloride of methylene, chloride of methyl, amylene, hydride of methyl and methylic ether, which promise to give us an anæsthetic without the danger and nausea of chloroform,—methylic ether seeming to be the nearest to perfection.

It has occurred to me that a promising field for investigation would be the study of the state of combination in which the more powerful active principles are found in the plant. The probability is that, whilst the more striking properties of an alkaloid, such as the narcotic effects of morphia, are seen in the free alkaloid or any of its salts, the action of the acid cannot be null. As, in mineral chemistry, salts containing the same metal differ widely in their properties, so it cannot be of indifference what acid we combine with vegetable alkaloids. It is fashionable to exclude all mention of design now, and to urge that quinine and morphine were meant for the use of man is to sacrifice one's reputation for scientific sanity; yet I cannot give up this old-fashioned notion, and, if it be true, is it not at least probable that the natural combination will have valuable properties? Meconate of morphia is a preparation in point, and quinate of quinine and igasurate of strychnine would, I think, be worthy of trial.

The pharmacist may say, what is all this to me? Simply this: he will have, ere long, to deal in these things; and ignorant handling of edge tools, as these unquestionably are, is a fertile source of accident. It should never be forgotten that to pharmacists we owe many of these potent remedies, and the names of Robiquet and Pelletier are indelibly associated with the organic alkaloids. We need not, however, confine our attention to organic chemistry; in mineral chemistry new remedies are constantly springing up, and the chemist should know what these new salts mean. In the old time, when there were scarcely any pure definite medicines, the chemist might do without chemistry, and his vegetable materia medica was the *sine quâ non*. Now we bid fair to make chemistry the chief study, and in the future the knowledge of the actual sources of our medicinal agents may be only interesting to pharmacists in general as objects of curiosity, which they are not called upon to handle.

In connection with this subject, it is remarkable that, at the last meeting of the Pharmaceutical Conference, the greatest prominence was given to such subjects as apocodeia, hesperidine and other definite chemical substances.

I therefore call upon all students—and, I trust we are all included in that class,—but especially on young men, to make their knowledge of chemistry, as of every other branch of study, thorough so far as it goes. "Learn to know it, not to know about it," to use Canon Kingsley's advice; and depend upon it you will pass a better examination, and more intelligently appreciate anything new than by an attempt at "technical" knowledge.

Cramming is the worst phase of this one-sided work, and should be hated as a lie. For it is a lie, it is a pretence of knowledge to veil ignorance, and like all lies, lands its user in disgrace And it is a transparent veil, for any examiner up to his work is sure to detect it; it has an artificial look and is sure to have weak points. Practical work is the best means of avoiding this snare, and although lectures, illustrated as fully as possible, are the best means of showing the formation of chemical bodies in the actual position of most pharmaceutical students who have no laboratories and not too much money or time, yet analysis, qualitative at least, can be carried on with half-a-dozen test-tubes and the chemicals around them. But then the knowledge of this should be more than that such a test reveals the presence of such an impurity, and then, when the reason of the test is shown, the student finds that each analysis includes a synthesis, and thus both sides of chemical practice are seen at once. The present state of pharmacy in England will justify me in making my address mainly a call to exact scientific knowledge. Knowledge was always good, now it is indispensable, and from pharmacy will shortly be banished the reproach that it was the one business that a man could conduct without any knowledge of the things he dealt in. The grocer knows the quality of his tea and sugar, the draper is profound in fractional differences of value in his wares, and the pharmacist should be at least as well informed in his line, nay, rather should be incomparably more so, for you or I can form a fair idea of our food and clothing for ourselves, but the outside world have and can have no means of ascertaining the value of what they get out of a chemist's shop, whilst the issues involved in the two cases have no standard of comparison. I shall survive a bad coat, and possibly may a cup of Moning congou, but the quality of a drug may make the difference of life and death. Who, then, will any longer speak of the hardship of having to prepare for so responsible a vocation?

Then the examinations have a distinct and definite value. Conducted under independent control, the public have a guarantee that they are a real protection, and Dr. Greenhow's report on the examinations will impart a confidence to the public which I fear they were losing. Perhaps the *Pall Mall Gazette* may have exaggerated the terrors of the public when it suggested the desirability of hanging a chemist, but such a suggestion would have fallen very flat if it had been known that every chemist knew what he was about and that no ignorant man was in the profession. In one generation this vision will be realized; and before that time year by year will thin the ranks of the incompetent, and swell those of men whom the world will trust without fear.

I have no wish to trespass on such dangerous ground as that of regulations for storing poisons. Yet the cry for them, not at all general I grant, seems to me the natural result of the action of chemists themselves. Have they not urged the importance of compulsory examinations, and pointed to the public the danger of uneducated men being allowed to handle poisonous drugs? Can it be wondered that the world believes what it has been so earnestly told by those who ought to know best, and that as the men are there and cannot be turned out, precautions should be insisted on? May an outsider, in one sense, be permitted to make the suggestion that voluntary regulations, to be any good in satisfying a public demand, must be made public, and that the world must know who does and who does not adopt them? I trust this guarded allusion to the subject may not expose me to the wild attacks of some warriors who show that, alas, man is a fighting animal by nature, and can hardly believe that any one who opposes them is sane or honest.

Few things are more remarkable in our English manners and customs than the respect we pay to the right of every man to do wrong. I know that there are laws and penalties for breaking them, but there is a tenderness, especially for highly respectable sinners, that contrasts sharply with the practice of our Continental neighbours, and even of the Americans. In nothing is this more strikingly shown than in our laws with regard to adulteration. First there is a statement that there is a great deal of adulteration, that adulteration is a very bad thing and ought to be punished; and then follows a law screening the malefactor in every possible way, and giving the utmost possible trouble to any one moving in the affair, coupled with conditions to render a conviction impossible unless the adulterator is an absolute ass, which, as a rule, he is not. The public conscience is then satisfied, and we wait for a time to see what will follow. Of course, nothing follows, until a roused British public again stirs itself, to be pacified with a repetition of the farce. Nothing will put down adulteration until the law makes the seller responsible for all adulterations, injurious or not, and then let him, if innocent of actual knowledge, have his remedy against the manufacturer. I say adulterations, injurious or not, for in many, nay, most cases, the admixture is one which no chemist can stand in a witness-box and swear is in itself injurious to health. It is robbery which is to be punished quite as much as doing bodily harm, but who can tell the injury done to health by a mere diminution of nutritive power in food by the addition of a substance harmless *per se*.

Certainly, if a man sold anything openly as a mixture, no objection could be taken; but what a disgrace to English tradesmen that it is supposed to be necessary to ask them if their goods are pure, and that if you do not, you are to have no remedy, the assumption being that you were a fool to trust to their honour.

Among pharmacists I am willing to believe that there is not much wilful addition to their drugs; and in this I am borne out by the analysis of some 150 articles purchased by the Sanitary Association of Manchester several years since and analysed in a laboratory in which I was an assistant. But the use of inferior qualities of drugs, I fear, cannot be denied, and no Act of Parliament will ever reach this. Nothing but a higher sense of honour, a feeling that it is a shame to violate the trust placed in them, which we may hope to be a result of higher education, will remove the temptation from what I believe to be a minority of pharmacists, to swell their profits this way. Of course, I may be told the public are themselves to blame, they will have food and medicine cheap, and therefore must have it so, and also nasty, but I do not see that this is the necessary result, and I would ask, is not the public more tempted than tempting?

A question which is in my opinion of the highest importance to you as subject to the Pharmacy Act, is, how this education, which we all say is a good thing, can be obtained? I have no means of obtaining a correct figure, but may say that in Liverpool there are many young men who will have to pass an examination before they can begin business.

For chemistry there are many places where instruction is given, though I regret that in connection with our own Association, the opportunities are imperfect. I should be glad to be able to afford time for two classes, in one of which the higher branches of chemistry, especially a fair amount of organic chemistry, could be taught. But this I cannot manage; and I am of opinion that it will be found necessary eventually to have an independent school of pharmacy, where instruction in all branches necessary to be known by pharmacists, can be obtained. But then two things will be necessary, 1st, a more thorough conviction on the part of employers that they have duties as well as rights towards young men in their employ. Opportunities for attendance on instruction must be more freely given, and not only so, but time for study. This no doubt involves the other question of late hours of business. I cannot work mentally with any effect when I am physically tired; and though there will always be a few who to indomitable perseverance unite physical strength, yet it is not fair to expect these advantages in all. 2nd. Those who enter upon this calling must expect to find their education costly in comparison with that of their predecessors. Education given gratis, or indeed at anything under the fair market price, ought not to be looked for, nor can it be depended upon as a certainty. To ask a young man intending to enter upon the calling of pharmaceutist to spend, say £10 each year of his apprenticeship on lectures and practical chemistry, may seem hard, but so far as his calling is to be looked upon as a profession, there must be a professional training. If this could be done in Liverpool, we could have proper systematic teaching, not spasmodic efforts, but a regular school, and surrounding towns would, no doubt, send us students.

During the session I hope this subject will have full consideration.

And now with regard to our own Association, in whose prosperity I have felt much interest ever since my arrival in Liverpool. There is always a risk of falling into a state of apathy in a society when its freshness of youth has gone, but I should like to see some new life invigorating it.

I hope that I have shown sufficient field for scientific chemistry in the department of pharmacy to induce the scientific chemists of Liverpool to take more interest in the Association. This is not a trade society, it does not lay down laws for the regulation of business, nor interfere with the right of every member to pursue his own course of action. Its expressed object is "the advancement of chemical and pharmaceutical science." All therefore who wish for this are welcome, and if they can tell us something new, whether money can be made out of it or not, they are doubly welcome. At the same time, the Association is not a speculative society, with no practical action. Business, yours and mine, must be attended to, we must live, at least *we* see the necessity; and improvements in carrying on such business, or social reforms bearing on it, are fair subjects for our consideration. Your Council in their report ask for more pharmaceutical papers. I hope I shall not be supposed to be advocating a course of opposition to the Council in any remarks that I have made, rather, as Arnold said of religious books, we do not want more of these, but rather works on secular subjects religiously treated, so I do not ask for pure chemistry papers, but pharmaceutical papers treated in the spirit of pure chemistry; and not chemistry alone, but botany, hitherto conspicuous by its absence, should have its fair share of attention, and I trust that materia medica, both chemical and botanical, will be represented in the report of the proceedings of this session.

The results of the microscopical examination of drugs as a test of their purity is another subject worthy of notice. In the discussions let there be life. If the reader of the paper is wrong, correct him; if you differ from him, do not fear to express it. I would rather be soundly attacked, and put on my mettle in defence, than receive nothing but formal thanks. Most readers of papers, I think, will feel with me that criticism—sharp, if necessary—is preferable to want of interest or unfelt adulation, so long as it is good-humoured and fair.

The Council's call for short papers I will endorse. It is a rather serious thing to set oneself the task of occupying an entire evening of the Society; but surely a single observation, fairly studied and worked out, is within the reach of many of our members. We should thus get some original observations, I hope, and greatly increase the value of our proceedings.

The session is now inaugurated, and its success depends upon you. The President has his duties, and will try to fulfil them; you have yours (strange as it may sound), and may I call upon you not to be mere recipients of the good things of others, but to be fellow-labourers.

I look for your co-operation and support. I take the chair with pleasure, as marking your appreciation, but not with self-confidence. With your help, I look forward to meetings pleasant and also profitable, and, when I lay down my office, shall be rejoiced to find that, in my hands, the Association has not suffered loss, but has been made more helpful to the best interests of the pharmacists and also to the chemists of Liverpool.

Mr. Shaw said he rose with much pleasure to propose a vote of thanks to the President for his able and practical address. The remarks in respect to adulteration he fully endorsed, and considered the admixture of innocuous substances with medicine or food highly censurable, although they might not be positively injurious to the system. The educational question was now coming prominently to the front, especially as regards the provinces, and will require to be dealt with more vigorously. Repeated applications for grants of money for the provinces had been before the Council in London during the past twelve months, and it was a subject requiring very careful consideration. The changes which had been brought about by the passing of the Pharmacy Act, pointed to the establishment of centres of education, and he hoped that Liverpool would not be behindhand. He alluded to the efforts made by the Birmingham Local Association to procure an efficient and inexpensive education on pharmaceutical subjects. With regard to our own Association, the President had rightly stated that membership of the Liverpool Chemists' Association was not confined to those following the profession of pharmacy, but included all who took an interest in the advancement of chemical science, and he trusted now that he (Mr. Davies) occupied the presidential chair, he would draw around him many young men who were engaged in the various chemical and other works in Liverpool and vicinity, and that the Association would continue to prosper and afford facilities for the instruction of the rising generation of pharmaceutists.

Mr. J. Abraham seconded the motion, which was carried with acclamation.

The President returned thanks, urging upon students the necessity of studying at home before coming to the lectures, if they wished to make satisfactory improvement.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Third Annual Meeting of the above Association was held in the Memorial Hall, Albert Square, on Friday evening, October 13th; the President, Mr. W. S. Brown, in the chair.

The Honorary Secretary, Mr. F. Baden Benger, read the following Annual Report:—

Your Council have again the pleasure of presenting a satisfactory report of the condition and prospects of your Association. Though the number of members and associates has slightly decreased, several having left the neighbourhood and a few declined to renew their subscriptions, the Association maintains its position as the largest provincial society of chemists and druggists, and inferior to none either in the importance of the work it has originated or the energy with which its objects have been promoted.

During the past session six ordinary monthly meetings have been held, at each of which a paper or lecture was given by a member:—"On Pharmaceutical Education and Apprenticeship," by Mr. F. Baden Benger; "On Heat," by Mr. J. T. Slugg, F.R.A.S.; "On Pharmaceutical Examinations," by Mr. Siebold; "On the Importance of Some Knowledge of Anatomy and Physiology to the Pharmacists," by Mr. Hampson; "On Dispensing," by Mr. Halliday; "On the Stars," by Mr. J. T. Slugg, F.R.A.S.

The associates of the Society also met weekly, during the winter months, in the Reading Room; at each meeting a paper was provided and a general discussion followed. Considerable additions have been made to the library, by purchase and donations. Mr. Joseph Ince may perhaps be specially alluded to as the donor of a very valuable collection of autograph prescriptions, which has proved so useful to the students. The reading-room has been opened three evenings a week during the year, and students have been admitted at any hour on application to the Honorary Secretary. Copies of the *Lancet*, *Pharmaceutical Journal*, *Nature*, *Chemical News* and the *Chemist and Druggist* have been laid on the table as published. The expense to the Association, thus incurred, for rent, gas, attendance, etc. has been great, but your Council believes that this effort to meet the requirements of assistants and apprentices has been appreciated by them.

The number of students attending the special pharmaceutical courses at Owens College was as follows:—Chemistry, 19; Materia Medica, 16; Pharmacy, 17.

The Botanical Course and the Latin Classes were open to others as well as pharmacy students, and the attendance was consequently much larger. Eight pharmacy students entered for three or more courses, and thus became entitled to the reduction in fees afforded by the College.

The special prizes given by your Association were awarded by the professors as follows:—

Chemistry Lectures.—Prize and First Certificate, Alfred H. Jackson; Second ditto, William Marsh; Third ditto, Walter Twelvetrees; Fourth ditto, Thomas Hart.

Materia Medica.—Prize and First Certificate, Alfred H. Jackson; Second ditto, John Thorpe; Third ditto, William Marsh.

Pharmacy.—Prize and First Certificate, Alfred H. Jackson; Second ditto, Frederick Richard Cooper; Richard E. Taylor; Fourth ditto, Charles James Wilcox.

Mr. A. H. Jackson took also the Second Certificate in the Lower Middle Latin Class and the Prize and First Certificate in the Botany Class; and Mr. William Marsh took the only certificate given in the first year's course of the Chemistry Laboratory Class.

A sum of three guineas has been presented by Mr. T. G. Gibbons, to be offered as a prize in any way your Council shall decide. The conditions upon which this prize may be competed for will be shortly announced.

At one of the monthly meetings of the past session the consideration of the proposed poison regulations was referred to your Council, with a request to take action thereon; this resulted, as is known to most of you, in the formation of the "Chemists' Defence Association," a society numbering upwards of 500 members. This Association, in conjunction with the "Metropolitan" and "North British" Associations, established with similar objects, was mainly instrumental in organizing a successful opposition to the Amended Pharmacy Act.

The monthly meetings of last session were held alternately in the afternoon and evening of the first Friday in the month, tea being provided half an hour before the commencement of business at the evening meetings; by this means, pleasant social intercourse was promoted. And it is now proposed to hold all the meetings in the evening, in order to afford as many assistants and apprentices as possible the opportunity of attending; the chair will be taken at 8 p.m., instead of 7. Tea, coffee and refreshments will be provided at half-past 7. Professor Williamson, F.R.S., will lecture at one of the forthcoming meetings; and for the remainder, well-known members of the Association have promised papers on subjects of much general interest: your Council trusts that these gentlemen may be encouraged by the large audiences they deserve. The objects for which your Association labours, viz., the higher scientific education of apprentices and assistants, mutual improvement and cordial intercourse, are so important to the whole trade, that your Council again urges you to make them widely known amongst your pharmaceutical friends, and by thus strengthening the hands of the executive, enable it to carry forward its original design of establishing in Manchester a museum and school of pharmacy.

Your Association has lost during the year a much respected member by the death of Mr. Charles Wright. It has also just suffered an almost irreparable loss by Mr. Robert Hampson's removal to London. Mr. Hampson has been one of the most active and zealous members of Council, and is known to all of you as the author of papers of very great ability, read at our meetings, and as the indefatigable honorary secretary of the Chemists' Defence Association. Mr. Hampson will carry with him the heartiest good wishes of every member and associate.

As will be seen from the Treasurer's statement, the financial position of the Association is good. In the general account there remains a balance in hand of £73. 6*s.* 10½*d.*, and in the library fund account a balance of £28. 5*s.* 1*d.* Under these circumstances your Council has abstained from making any application for aid from the funds of the Pharmaceutical Society.

The Treasurer, Mr. G. S. Woolley, then read his statement of accounts as follows:—

The Treasurer in Account with the Manchester Chemists and Druggists' Association.

The Chairman in moving the adoption of the report, congratulated the members on the fact mentioned in the report, that their Association was the largest of a similar character in the provinces; at the same time it was a matter of regret to the Council that the Society was not much larger, the number of those connected with it was slightly smaller than last year, and very considerably less than in the previous one; he was grieved to have to state that the entries made for some of the classes at Owens College had not been yet sufficient to ensure their commencement. These classes had been the hope and pride of those who had taken the trouble of organizing them; every endeavour had again been made to bring them under the notice of those for whom they had been intended; a special circular had been issued by the Secretary, but a general indifference seemed to prevail. The allusion made to Mr. Hampson in the report was well deserved. Some of the most important work done in connection with the Association had originated with him. The paper read by him before the Association, on "Remunerative and Uniform Dispensing Charges," had resulted in the issue of a scale of prices, which had proved most useful in their own city and had been very widely adopted in other towns. Mr. Hampson's connection with the Defence Association had involved the expenditure of much time and money. He (Mr. Brown) hoped that the poison regulations question would not be again raised in Parliament; but, should it be, he believed that the same energy which Manchester and other places had displayed would again defeat it. It was the intention of the Council to make, during the present session, considerable additions to the library and museum; and should the income of the Association justify it, to take larger rooms for the accommodation of students. It would be, he was sure, a source of satisfaction to all connected with the Association to know that it had preserved its independence, and had neither received nor asked assistance from the funds of the Pharmaceutical Society, knowing how much those funds were needed by smaller and weaker associations.

The adoption of the report was seconded by Mr. Varey Pickup and carried unanimously.

Mr. G. S. Woolley, in proposing the re-election of the President, after alluding to the obligation the Association was under to Mr. Brown for his zealous and constant efforts for its advancement, said his name should be coupled with Mr. Hampson for his self-denying exertions in opposing the Amended Pharmacy Bill.

The resolution was seconded by Mr. Bostock (Ashton) and carried with acclamation.

Messrs. Slugg and Wilkinson were then re-elected Vice-Presidents; Mr. G. S. Woolley, Treasurer; and Mr. Benger, Secretary.

Messrs. Hall (Salford), Mumbray (Higher Broughton), J. Waterhouse (Ashton) and Hermann Woolley (Market Street) were elected to fill vacancies in the Council; and Messrs. Standen Paine and C. A. Johnstone, Auditors.

Mr. G. S. Woolley expressed the pleasure it gave him to see many associates present who took an active part at the weekly meeting of assistants held in the reading-room last session. He had frequently heard from students how much assistance they had derived from the collection of materia medica and botanical specimens in the room; his firm would be glad to replenish the drawers when necessary.

Mr. Benger said he could not allow that occasion to pass without expressing the very great regret he felt at the threatened collapse of some of the pharmaceutical classes at Owens College. He felt that it was a very great humiliation, not only to the Association, but to the great city of Manchester and surrounding district, that there were not found ten men to save the honour of the Association and of the trade by supporting the pharmacy and materia medica courses. It was not yet too late to retrieve that honour: a few more entries would save them from the disgrace of breaking down, and he hoped that those names might yet be sent in. With regard to the evening meetings, their interest and usefulness might be greatly extended by the more cordial co-operation of associates. Though the primary object of making communications to the evening meetings was undoubtedly to give information, a secondary and scarcely less important one was to elicit it; and he felt sure that there was scarcely an assistant or apprentice present who did not meet with some little pharmaceutical difficulty, or interesting fact worth investigating, during the month between the meetings. If they would forward to him any such queries, he would take care that they should be introduced at the next meeting. The discussion thus induced would probably prove useful to all.

Mr. Louis Siebold (Lecturer on Pharmacy at Owens College) then made some observations on what he believed to be the chief causes which had operated against the success of the College courses; it grieved him to say that it was mainly the indifference of those for whom they were intended. When he remembered that in 1868, immediately after the passing of the Pharmacy Act, they had in Manchester classes of upwards of fifty young men studying these subjects, and that comparatively few of these had passed their examinations, he knew that the material for large classes still existed; at the same time he knew of many instances in which the responsibility rested with the masters, who refused to allow their *employés* the necessary time. In one case which had come under his notice, a master had insisted on an apprentice serving one day in addition to his term of apprenticeship for every day he had attended lectures. He believed that the difficulty was only a temporary one; not one apprentice in twenty could pass his examinations without assistance, and sooner or later they would have to seek that help which they now rejected.

The Chairman then announced that the next ordinary monthly meeting would be held on Friday evening, November 3rd, when Mr. Wilkinson would read a paper "On Some of the Difficulties of Practical Dispensing." There would be tea at half-past seven, and the chair would be taken at eight o'clock.

Parliamentary and Law Proceedings.

Poisoning by an Overdose of Morphia.

On Saturday morning, October 14, an inquest on the body of Dr. Poole, was held at Hyde. Deceased was found dead in bed, and the evidence that was given conclusively proves that his death was the result of an over-dose of solution of morphia, administered in all probability whilst partly intoxicated.

Mrs. Wilkes said deceased's name was John Poole; he practised medicine, but she did not know whether he was properly qualified. He succeeded to the practice of her late husband. He went to bed on Wednesday night about half-past eleven, at which time he was slightly intoxicated. As he did not come down at his usual time next morning, his room was entered and he was found dead. The small bottle produced generally stood on the drawers, but on the morning of his death it was on the corner of the dressing-table. On Wednesday morning there was about an ounce of the solution of morphia in it. Deceased had had *delirium tremens* slightly.

Samuel Beecroft deposed that he was a surgeon, practising at Hyde, and had made a *post-mortem* examination of the deceased. There were about eight ounces of fluid in the stomach, but no food; the fluid smelt strongly of whisky. The mucous membrane was much inflamed, probably through the spirit. On making the necessary tests he found distinct evidences of morphia, and had no doubt he died in a state of coma produced by morphia. There would be about 4 grains of morphia, and 1 grain had frequently caused death. Deceased might not think it an overdose.

The Coroner said, there could be no doubt from Mr. Beecroft's testimony and the other evidence given, that deceased died from an overdose of morphia, and that he did not take it for the purpose of destroying himself, but that it was simply an overdose taken incautiously, he being at the time in a state of intoxication.

The jury concurred in the coroner's views, and a verdict was returned accordingly.

Cases of Poisoning by Laudanum.

The *Sunderland Times* reports that an inquest was held on Tuesday, September 3rd, at Millfield, on the body of William Hay. According to the evidence the deceased was found asleep in the taproom of a public-house. Medical assistance was obtained, but death ensued about two hours after. From a *post-mortem* examination, the doctor was of opinion that deceased died from poisoning by laudanum.

An assistant to Mr. Walton, chemist, stated that he had sold to a man, whom he could not identify as deceased, two drachms of laudanum for a penny. The bottle and label were similar to those produced. The man said he wanted the laudanum for his sister, who had a pain in her side. This witness incidentally stated that he had two or three times seen women drink off a pennyworth of laudanum while standing in the shop.

A verdict was returned that the deceased died from poisoning by laudanum, but whether taken intentionally or accidentally there was no evidence to show.

Another case of poisoning by laudanum is reported from Saffron Walden, where Mr. David Archer has taken an overdose which caused his death. Deceased had purchased an ounce of laudanum from Mr. Gilling, chemist, stating that he wanted it for cattle. Shortly after his return home he was found in an unconscious state, and spite of every effort to restore him died, after lingering for some hours. The jury returned a verdict of death from an overdose of laudanum taken by misadventure.

On Monday, October 16th, an inquest was held at Brighton to inquire into the death of Barbara Chapman, a single woman, who was found dead. Evidence was given that the deceased, who was addicted to drink, was in the habit of taking laudanum for the purpose of obtaining sleep. In the room in which she was found there was a bottle labelled "Laudanum—Poison," with the name of Mr. Curtis, chemist, on it. Downstairs was another, similarly labelled, with the name of Mr. Pain on it, and in a workbox another that had been obtained from Mr. Rowsell. Deceased had applied for sixpennyworth of laudanum at Mr. Curtis's, but only one pennyworth had been supplied to her, and the same quantity was supplied to her by Mr. Pain.

Medical evidence was given to the effect that the deceased had died from an overdose of laudanum. The jury returned a verdict accordingly, and expressed an opinion that it had been taken incautiously, without an intention to commit suicide.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

A CHEMICAL CURIOSITY.—The potassio-chromic oxalate described in Fownes' 'Chemistry,' p. 778, presents the curious anomaly of being pure deep blue in crystal, claret-red in strong solution, and dusky green when further diluted.

The crystals appear black by reflected light, and the blue is only seen in their thin edges. A solution prepared by dissolving 10 grains of potassium bichromate, 20 grains of oxalic acid, and 20 grains of potassium binoxalate in hot water, and diluted so as to fill a four-ounce white flint square, displays the red colour when seen in the direction of the longer diameter of the bottle, and the green when viewed through the shorter. —J. F. Brown.

[285.]—SYRUPUS CROCI made by form given on page 707 is not very satisfactory; a portion of the sugar remains undissolved at the bottom of the syrup bottle, and the syrup (?) above is in a gelatinous state, so the bottle may be turned upside down and well shaken without the contents leaving. Colour and smell are good, the only fault apparent is that of its being a little too thick.—IOTA.

[286.]—DISPENSING.

℞ Spt. Ammon. Co. ʒss
Liq. Ammon. Acet. ʒij
Quinæ Sulph. gr. x
Liq. Morph. ʒj
Spt. Ether. Nit. ʒiss

Liq. Ammon. Acet. ʒij
Liq. Morph. ʒj
Spt. Ether. Nit. ʒiss.

—C. H. SNELL.

[287.]—HOTCHKISS' OIL OF PEPPERMINT.—Your correspondent "*Philos*" is labouring under a difficulty, the counterpart of which I have for a long time experienced. Like himself, I was a few years ago able to buy Hotchkiss' ol. m. pip. which was perfectly soluble in sp. vin. rect. 56 o. p., one part to seven. I now use sp. vin. rect. 60 o. p., but still have the result he complains of, viz. a milky fluid, which no kind or extent of paper filtering will clear. When first made, and for a considerable time after, the mixture is unsaleable; but in the course of four or five months it loses, in some degree, its turbidity, and becomes comparatively clear, depositing on the sides and bottom of the vessel in which it is made a dirty precipitate. I have hitherto been unable to find out any other means of getting over the difficulty, except by making my stock of ess. menth. pip. some six months before it is wanted.—F. R. B.

I find that the oil of peppermint manufactured by L. B. Hotchkiss will become milky if mixed with more than an equal volume of S. V. R. 56 o. p.; but the mixture becomes clear if kept for a few days, and a kind of resin is deposited. I should like to know if any of our fellow readers can tell us what this resin is; if it is used as an adulteration, or is an impurity in the oil.—FERRUM.

My experience coincides with that of "*Philos.*" Hotchkiss' ol. m. pip. did formerly dissolve at once in sp. vin. rect. For a long time it has not done so. If "*Philos*" will put the turbid liquid by for a fortnight, it will clear itself; or if a little magnes. carb. is added to it, the effect will be much expedited.—IOTA.

The milkiness complained of upon mixing the oil with sp. vin. rect. 56 o. p. is entirely removed by adding a little magnesia, shaking it occasionally for a few days, and then filtering.—J. W. HADINGHAM.

S. P. Z. R. suggests the same remedy.

[290.]—MILDEW.—"*Primus*" asks to be informed of an effectual remedy for mildew.

[291.]—GOLDEN INK.—Will any correspondent oblige me with a receipt for golden ink, which is used for gilding, writing, etc.?—SENEGA.

[292.]—ZINCI OXID. BENZOAS.—Can you furnish me with a form for making zinci oxid. benzoas?—A. A.

[293.]—DISPENSING.—Will some of your readers inform me how they would dispense the following prescription?

British Pharmacopœia.

℞ Potassæ Chloratis, 2 oz.
Aquæ, 18 fl. oz.
Tinct. Aurantii, 12 fl. drs.
Tinct. Cinchonæ Flavæ Liquid. 4 fl. drs.

Mix and label two small tablespoonfuls with the same quantity of water twice a day, 10 A.M. and 8 P.M.
—X. Y. Z.

PROVINCIAL EDUCATION.

Sir,—Mr. Smith's thoughtful and suggestive paper forms an excellent groundwork for discussing the important and too-long neglected question of provincial education. For a long period of years provincials have contributed largely to the educational establishment in Bloomsbury Square, without receiving or expecting any very direct benefit in return. Mr. Mackay, in his address, remarked that as an educating body its days were probably numbered; and, however startling the prophecy may be, there is little doubt of its truth, such a result being a natural sequence of the legislation of 1868.

In the face of such a probability, it is the plain duty of the Council to encourage by every means in their power the establishment and development of schools of pharmacy throughout the provinces, and provided no parliamentary ghost appears, much may be accomplished in a year or two.

A few provincial schools have been started,—I fear it can hardly be said established,—each groping its own way, but as yet making little real progress, mainly for want of a directing power at the helm. I trust the able letter of Mr. Smith, and the discussion arising thereon, will lead to a better state of things.

The sectional arrangement of Mr. Smith accords exactly with that adopted by our Hull Association two or three years ago. We do not, however, disregard the education of assistants, but admit them on equal terms with apprentices, for in many cases they need our sympathy, having unexpectedly to undergo an examination not contemplated when they entered the trade. We also allow them to compete for senior prizes.

I think all will agree that the management of provincial schools must of necessity be in the hands of local associations, assisted, if need be, by liberal grants from the parent society; the grants at present made are not only small in amount, but clogged with such conditions as to rob them of half their value. A very small portion of the large funds of the Society, judiciously and generously applied, would greatly stimulate local efforts, and that to an extent far beyond the mere money value of the grant.

From a long experience in national and other schools, I can affirm the value of independent periodical examinations in maintaining the tone of a school, and I trust that Mr. Smith's suggestion will not be lost sight of. Centres of examination are also desirable.

Schools, however, must of necessity precede examiners; it appears to me, therefore, that immediate steps should be taken to establish, in all large towns at least, efficient schools of pharmacy, each working in harmony with a general plan approved or arranged by the Council, yet sufficiently elastic to admit of ready adaptation to the wants of various localities.

My own experience leads me to the conclusion that the Pharmacy Act is not popular among country chemists; they are therefore, in many cases, indifferent to the claims made upon them for education, and the work and cost falls upon comparatively a small number of the body. Under these circumstances, if the Council expects the schools to succeed, both moral and material aid must be offered, for a time at least, to those willing to engage in the work.

In Hull we have made a fair start in the matter of technical education, but I am satisfied we shall not succeed in permanently establishing our school of pharmacy without a liberal subsidy from the parent Society. So far we have gone on in the expectation something would be done, and I would fain hope the good time is now coming.

There are other parts of Mr. Smith's letter I should like to comment upon, but consideration for your space forbids at present.

JAMES BAYNES.

Hull, Oct. 17th, 1871.

Sir,—Mr. Edward Smith, in his paper on "Provincial Education," which appeared in last week's Journal, divides his subject into three heads,—the students, their studies, their teachers. To his definition of the first, and his proposed line of action for the third, I would heartily agree, but must to some extent differ with him on the second head. He would, if I rightly interpret his idea, make it the great object of country associations to prepare students for the Minor. Working on this principle, they will soon degenerate into copies of those London establishments which guarantee to prepare gentlemen for their examinations in one month; and of those thus prepared, or rather "crammed," with lists of names and crude facts which just enable them to squeeze through the Minor, how many will care (without the Association's help too) to thoroughly master the several subjects of study, and go on to the Major? That the cram system is that desired by most of the apprentices I readily admit, but cannot think that it is the proper one. Let the course of study undertaken be thorough, without reference to any examination, and though the way be thus made a little longer, the student will find that, instead of crossing the Minor on a tottering plank, which lands him on the other side in a pathless forest, he will cross by a good stone bridge, from which a well-macadamized road, along which he can travel with ease, leads straight to the Major.

Norwich, October 16th. PHILIP H. MASON.

THE COUNCIL OF THE NORTH BRITISH BRANCH OF THE PHARMACEUTICAL SOCIETY.

Sir,—Having been out of reach of the Journal for a few weeks, I have been unable to draw attention so soon as I would have liked to Mr. Mackay's reply to my letter of the 26th August. In that reply, he says "That the name (North British Branch) was given by Jacob Bell; that it has remained unchallenged for nineteen years;" and "that it became necessary that a committee should be appointed to look after the various matters in connection with the examining board." "These gentlemen," he says, "formed, and still form, the Council at Edinburgh." May I ask, if Mr. Bell bestowed the title "North British Branch," why they did not adhere to it during all these nineteen years which Mr. Mackay boasts so much about? On reading Mr. Mackay's statement I was convinced that there was a discrepancy somewhere, and to satisfy myself, as well as to take advantage of the advice tendered by Mr. Mackay, I went over a few of the back volumes of the Journal, and found, as I expected, that the title "North British Branch" was not adopted until 1869. I find that on the evening of Friday, 17th April, 1868, the "Edinburgh Pharmaceutical Society" held their annual meeting, Mr. Young, President, in the chair, and, amongst other business, Mr. Ainslie was elected President. Then, in the 1869–70 volume, I find the report of the annual meeting of the "North British Branch" of the Pharmaceutical Society, held in Slaney's Douglass Hotel, on Thursday evening, May 27th, 1869, Mr. Ainslie, President, in the chair. When was Mr. Ainslie elected President of the "North British Branch," and when was the high-sounding title adopted originally? Of this we have no record, in the Journal at least, though it doubtless exists in Mr. Mackay's brain. Then, again, if Mr. Bell really gave it the high-sounding title years ago, does Mr. Mackay mean to insinuate that it was his intention that his elected few should keep the title exclusively to themselves, and remain in office for life. But perhaps our Edinburgh friends will go a step further and hand the title down to the third and fourth generation. I think, however, this was not Mr. Bell's intention; from what I have learned of him, he was too open-hearted a gentleman to give occasion for any such notion, and if he did say that a North British Branch should be started, he meant that it should exist on the same footing as the London Council, at least that all members of the Society in Scotland should have a voice in the election of the Council in Edinburgh, and if, as Mr. Mackay says, they have no power to do so, let them take the power. If they had adopted a constitution for themselves, and made a small fee, say of 5*s*. a year, for the title of membership; then no one could object to them using the title "North British" or any other they chose. As it is, they are certainly in an anomalous and unenviable position, in their using such a high-sounding title, and, at the same time, retaining all the privileges and advantages to themselves. Mr. Mackay says, that if the members in Scotland claim a right to elect the Council, so will the English members; but I do not see it in that light, what was the use of legislating, specially for Scotland, if she was not to have exclusive rights? More especially when everything done by the "North British Branch" is under veto of the London Council.

But apart from the question of the Edinburgh Council, I would ask, is it advancing the interest and raising the standard of the pharmacist to put up special pharmaceutical preparations and push their sale amongst grocers, hucksters, etc., enabling them to undersell the legitimate vender, or to reduce the prices for dispensing to such a low scale that it is really a wonder that a Pharmaceutical Chemist exists in the west of Scotland at all? Some of the most prominent members of this Council do this, belonging both to Edinburgh and Glasgow, and I can only say shame to them and their boasted position of leaders of the Pharmaceutical Society of North Britain.

October 10th, 1871. M. P. S.

TINCTURE PRESSES.

Sir,—I fear Mr. Staples has misconstrued my letter upon tincture presses, published in your issue of October 7th, 1871.

I there intended to show that the power of the one-gallon tincture press, "as ordinarily met with in trade," was not 20 tons, as represented by him in his paper read before the Pharmaceutical Conference, but theoretically only $4\frac{3}{4}$ tons; and when the deduction was made for friction about 2 tons.

Upon the press designed by Mr. Staples I did not comment.

It seems that Mr. Staples' calculations were based upon data (as far as dimensions were concerned) the accuracy of which he had not previously ascertained, whereas my calculations were framed from actual observation in the druggists' sundriesmen's warehouses in this city. The only other difference influencing the computation was the force applied at the extremity of the lever.

I imagine that although your readers (myself included) look upon Mohr and Redwood's 'Pharmacy' as a standard work upon all that is practical in connection with our calling, still they would not take everything as there stated (and especially when upon a subject that more properly belongs to the engineer) as an indisputable fact. My authority was Professor Rankine, whose writings are considered by practical engineers as standard works.

Mr. Staples, I have no doubt, read in your last issue a letter from the eminent hydraulic engineers, Messrs. Hayward Tyler and Co. In introducing their combined screw and hydraulic press, they compute a man's power at the end of the tincture press lever as equal practically to *fifty* pounds. Surely they would not have taken the force applied as equivalent to fifty pounds only, had *one hundred pounds* been the actual power that could be used, for thereby they would have undervalued the power of a machine, the superiority of which over the screw tincture press they wished to show.

In conclusion, I beg to assure Mr. Staples that nothing was further from my intention than the "courteous sarcasm" for which he gives me credit.

Laboratory, 40, *Aldersgate Street.* CHAS. UMNEY.

Sir,—When last week I wrote my reply to Mr. Umney, I had never computed the power of my own press. I was so satisfied at having obtained an implement that did its work well without much labour, yet so effectually that the marc appears as if dried, rather than only pressed, that I never troubled myself with any useless calculations about it, for they are but theoretical although giving a proximate estimate of mechanical force. The result led me to suppose that I had increased the power, but I never knew to what extent until Mr. Umney's criticism (PHARM. JOURN. October 7th) induced me to measure and calculate it. I now beg most cordially to thank that gentleman for teaching me its value, for I am really astounded to find how far it surpasses that of the press in general use. In my original paper on the tincture-press (*vide* PHARM. JOURN. September 9th) I supposed one yielding a theoretical pressure of nearly twenty tons. 100 lb. power being multiplied over 400 times, the figures were merely assumed for the convenience of illustration, as there stated. Now I learn from Mr. Umney that in practice these implements are manufactured with such huge bulk of screw that the calculation only works out to about half this result. If then my estimate of twenty tons (theoretical) pressure from a good screw-press of the ordinary construction is so exaggerated, what will be said of the power of my press? I feel some diffidence, almost hesitate to quote the figures, for fear that some of your readers, not working out the calculation, may think them fabulous; figures, however, like facts, are stubborn things. My press has two screws, the threads are one-eighth of an inch, with levers of seven inches radius, consequently each screw multiplies the power $7 \times 6 \times 8 = 336$ times. As to the power, with all respect for Mr. Umney's opinion, yet guided by that best of all teachers, my own experience, aided by the experience of others with whom I have conversed, also by the excellent authority of Professor Redwood ('Practical Pharmacy,' p. 107), I continue to average at 100 lb., this would give a total for both screws of $336 \times 100 \times 2 = 67{,}200$ lb., or *thirty tons!*

Now, if this result is obtained from an implement rudely constructed as a working-model, what may we expect from one of superior workmanship, with a further multiplication of power, which could be most effectually obtained by reducing the screw-thread, and as this would also diminish friction, a double benefit would be obtained? In my paper (PHARM. JOURN., September 9) I explained why it is impracticable to reduce the size of the screw in the ordinary press; but in mine it can be safely reduced to any reasonable extent. No amount of power so applied can injure it, provided the cross-bar is kept in a nearly horizontal position by a turn or two of each screw alternately. We will suppose a press, constructed on my model, with a pair of highly-finished steel screws, with threads one-twelfth of an inch, which should be cut deep into the rod so as to present an angle more acute than usual, say about 45°, with levers of 8 inches radius; this would multiply the power over a thousand times ($8 \times 6 \times 12 = 576$ for each screw), giving, with 100 lb., a theoretical pressure with greatly reduced friction of over *fifty tons!* Such an implement would be convenient, portable and not expensive, yet giving a magnificent power, fully up to the requirements of the pharmaceutical laboratory, even if it did not entirely supersede the hydraulic and all other presses; but these figures are but theoretical. Now, I am a practical man, and would rather have a thing done than talked about; perhaps one of your readers now wanting a good screw-press will have one made as I suggest (I know it would prove a most profitable investment), and then put it to the test; let a gallon, say of tincture of orange peel, be made for actual use and pressed by it, and another gallon made at the same time and under similar circumstances be pressed off by the best screw-press that can be obtained of the ordinary construction, and note the result, the measure of product in each case, weight of marc, also time, labour and trouble. This would be of more value than all the theoretical calculations or anything that could be said or written about it for the next twelve months.

October 16*th*, 1871. C. A. STAPLES.

E. H. S.—(1.) Pulvis Tragacanthæ Compositus is undoubtedly intended. (2.) Ferrocyanide of Potassium is not a "poison" under either schedule of the Pharmacy Act, 1868.

T. B.—Wanklyn and Chapman's 'Water Analysis' (Trübner).

J. B. B.—See a series of articles on the Cultivation of Medicinal Plants at Hitchin, PHARM. JOURN., 2nd Series, Vol. I. pp. 275, 323, 414, 515. Also an article on the Cultivation of Medicinal Plants at Mitcham, PHARM. JOURN., 2nd Series, Vol. VI. p. 256.

"*A Minor Associate.*"—(1.) Ung. Plumbi Subacet. Co. made as you state, does change from a yellowish colour at first to a white, and it afterwards assumes a bluish tint on the surface, but will be found white below. If made with almond oil, the ointment also soon gets a surface coating of an orange colour. We are unable to explain the causes of these discolorations. As the ointment quickly becomes rancid, it should not be kept long prepared. (2.) Camphor is destructive to some parasitic growths, but that it has any further action as a "disinfectant" we very much doubt. (3.) Bran does contain albuminous matter, phosphates, etc., which are soluble to some extent when taken as food, but its action is generally considered to be mechanical. (4.) "Species" should be translated "species." You might label the ingredients "species for infusion."

"*A West-End Chemist's*" letter is too personal for insertion. Would it not be better for him to inquire from the firm referred to what they really did charge?

L. S.—To make ten pills, the prescription sent may be readily dispensed thus:—

℞. Quin. Sulph. et P. Zingib. ana gr. x
Ferri Sulph. Exsic. gr. vj (=gr. x of crystals)
Ol. Menth. ♏x.

Adde: P. Trag. Co. gr. iij.
Syrupi Simp. ♏x.

Rub the sulphates to a fine powder; add the other dry ingredients and the oil; lastly, the syrup. Mix well, and roll out quickly.

CHLORAL.

BY W. A. TILDEN, D.SC., F.C.S.

A little more than two years ago the notice of the world was drawn to the remarkable physiological action of a substance, which at that time had probably been not even seen by more than a few individuals, and of which the quantity then in existence might be estimated by ounces.

At present it is bought and sold by hundreds of pounds.

In consequence of its production upon so large a scale, and of having become, in so pure a form, a regular article of commerce, chloral has latterly received from chemists a very considerable share of attention. Apart from considerations connected with its employment in medicine, a body of characters so singular deserved that its chemical history should be studied more closely than had hitherto been the case.

Experiments upon chloral, upon its hydrate, and upon other bodies more or less nearly related to it, have multiplied. Most of them are, however, of comparatively recent date, and are consequently not yet to be found in books.

Manufacture.—As every one knows chloral is made by passing chlorine gas into alcohol, mixing the product with oil of vitriol and rectifying. But the number of precautions to be taken to ensure a successful result, can only be properly appreciated after experience in the operation. The main points to attend to are, it seems, two:—the chlorine and the alcohol must both be absolutely free from moisture, and the current of chlorine gas must be maintained slowly but continuously from beginning to end. The chlorine is rapidly absorbed at first by the alcohol, but after a time it is necessary to heat the spirit until towards the close of the operation it boils. This must of course be done in an apparatus connected with a proper condensing arrangement, that the volatilized portions may not be lost. A yellow liquid ultimately results, which is agitated with oil of vitriol; the lighter part is separated and rectified from some fresh acid. The resulting anhydrous chloral is finally distilled from some quicklime, to remove hydrochloric acid, and then converted into the hydrate by mixing with the theoretical proportion of water.

It is necessary to exclude water from the materials employed, from the fact that chlorine in presence of water acts upon organic bodies, not by substituting itself for their hydrogen, but by oxidizing them. Consequently, when water is present, the aldehyd and acetic acid that are usually unavoidably produced in small quantity become the chief results of the reaction.

It appears that alcoholate of chloral is the immediate offspring of the action of the chlorine, and that from this chloral is set free by the sulphuric acid afterwards used. Water is, however, certainly formed in small quantity by a secondary action, and therefore a little hydrate is probably present as well.

Theory of the Process.—There can be little doubt that the chloral results from the removal of two atoms of hydrogen from the alcohol with production of aldehyd, and the conversion of this body into chloral by the replacement of three of its atoms of hydrogen by three chlorine atoms. Of course, a large quantity of hydrochloric acid results simultaneously.

$$\text{I. } \underset{\text{Alcohol.}}{C_2H_6O} + Cl_2 = \underset{\text{Aldehyd.}}{C_2H_4O} + 2HCl.$$

$$\text{II. } \underset{\text{Aldehyd.}}{C_2H_4O} + 3Cl_2 = \underset{\text{Chloral.}}{C_2HCl_3O} + 3HCl.$$

And it is interesting to observe in connection with this, that from aldehyd itself chloral is obtainable by the action of chlorine, if precautions are taken to remove the hydrochloric acid as it is produced.

Chloral, however, is not by any means the only resultant of the reaction of chlorine upon alcohol. The subordinate interchanges which go on at the same time are complicated, and result mainly from two causes, one the influence of the hydrochloric acid generated, and the other that of the chlorine, which affects, on the one hand, the matters to which the action of the hydrochloric acid gives birth, and on the other hand the impurities in the spirit. These must be examined separately.

The action of the hydrochloric acid upon the unaltered alcohol gives rise to the formation of hydrochloric ether or chloride of ethyl.

$$\underset{\text{Alcohol.}}{C_2H_5HO} + HCl = \underset{\text{Ethyl Chloride.}}{C_2H_5Cl} + H_2O.$$

But hydrochloric acid, in the absence of water, or even in concentrated solution, is a powerful promoter of what is called condensation. It does this by taking from two or more molecules of a compound body the elements of water, the residues of those two molecules uniting into one.

In a great deal of the spirit employed on the Continent in this manufacture aldehyd already exists in appreciable amount, and from this is formed a curious substance, which has been repeatedly observed and minutely examined. It is crotonic chloral, a body which stands in the same relationship to crotonic aldehyd that ordinary chloral does to acetic aldehyd. It is formed in this way:—From two molecules of aldehyd a molecule of water is detached by the hydrochloric acid. This gives crotonic aldehyd, which, at the moment of its formation, is attacked by the chlorine passing through the liquid, and converted into the new chloral.

$$\underset{\text{Aldehyd.}}{2(C_2H_4O)} - H_2O = \underset{\text{Crotonic Aldehyd.}}{C_4H_6O}$$

$$\text{and } \underset{\text{Crotonic Aldehyd.}}{C_4H_6O} + 3Cl_2 = \underset{\text{Crotonic Chloral.}}{C_4H_3Cl_3O} + 3HCl.$$

It is possibly by an analogous reaction that the small quantities of ether which it is believed are formed in the process may also result. This is, however, open to question.

The foreign substances which occur in spirit of wine are very numerous.

Water.—Although but minute quantities are present in the alcohol to start with, the amount, as already explained, is liable to increase. To this cause is due the production of acetic acid.

$$\underset{\text{Alcohol.}}{C_2H_6O} + OH_2 + Cl_2 = \underset{\text{Acetic Acid.}}{C_2H_4O_2} + 2HCl.$$

Fousel Oil.—This name is applied to the mixture of alcohols of higher boiling-point than ordinary alcohol, which is separated from spirit by the process of rectification. Propylic, butylic, amylic alcohols, and the corresponding iso-alcohols are among the constituents of this complex mixture, which have been observed. Acted upon by chlorine they probably yield products analogous to those formed from ordinary ethylic alcohol, but inasmuch as they are present in only small amount, they do not interfere seriously with the production of chloral.

Aldehyd.—This has already been mentioned as the source in foreign spirit of crotonic chloral.

As concomitants of the chloral we have then already chloride of ethyl, crotonic chloral, acetic acid, ether (?), and the numerous compounds derived from the fousel oils. But this is not all. These substances are, most of them, susceptible in their turn of the substituting action of chlorine. Thus from chloride of ethyl may be formed the following series:—

Ethyl Chloride . . .	C_2H_5Cl.
Monochlorinated " " . . .	$C_2H_4Cl_2$.
Dichlorinated " " . . .	$C_2H_3Cl_3$.
Trichlorinated " " . . .	$C_2H_2Cl_4$.
Tetrachlorinated " " . . .	C_2HCl_5.
Pentachlorinated " " . . .	C_2Cl_6.

From ether a similar series results, and probably all the other compounds referred to as originating in the fousel oils, yield by the same action at least one chloro-substitution product.

(*To be continued.*)

THE ESTIMATION OF COLOUR IN LIQUIDS.

BY BOVERTON REDWOOD, F.C.S.

Secretary and Consulting Chemist to the Petroleum Association.

It occasionally happens that the estimation of the amount of colour in a liquid is an operation of considerable importance. The following remarks have special reference to a notable instance of this afforded in the case of refined petroleum, the commercial value of which is to a great extent dependent upon its colour; since, however, they are in the main applicable to many other cases of a similar nature, not only in technical, but also in scientific chemistry, they may be considered to be of general interest.

The colour of refined petroleum has usually been measured by comparison with samples kept as arbitrary standards; such standard samples being in this country commonly contained in glass bottles of the ordinary form, and about 8 inches in height, while in America square bottles are preferred. The first difficulty in this mode of operating to which reference may be made, arises from the liability of the standard samples to change colour, and this is but imperfectly overcome by keeping the samples protected from the action of light. The Americans have, however, provided a remedy, which consists in the use of stained glass bottles, which, when empty, are the same colour as "white glass" bottles filled with the standards. This ingenious device is nevertheless no remedy for the next difficulty which lies in the fact that in cases of dispute, which not unfrequently occur between buyers and sellers, the system of comparing in bottles is not found to be sufficiently delicate; and opinions frequently differ as to whether a certain sample is equal to the standard or not, especially when the samples are observed against a clear sky, the blue colour of the firmament forming a bad background. The obvious way out of this dilemma was to employ a larger body of liquid, and Letheby's water-tubes, long test-tubes, or tall hydrometer-glasses held over a white plate or sheet of paper, have been used to contain the samples. The fluorescence of the liquid, however, prevented this mode of procedure from being as applicable as in the case of potable waters, for instance; and although the fluorescent appearance may be got rid of by coating the sides of the vessels with some opaque material, the plan hardly answered better than that of comparing the samples in bottles, until it occurred to Mr. R. P. Wilson (London), who with the writer was engaged in the determination of the colour of certain specimens of petroleum, to place a mirror beneath the tubes as a substitute for the white plate. It was at once evident that this constituted a great improvement, for instead of having to look down the two tubes alternately, it was merely necessary to glance at the mirror, where two well-defined discs of colour corresponding to the colour of the liquids appeared in juxtaposition convenient for comparison. Mr. Wilson was, however, not content with this arrangement, which was still subject to the objection attaching to the use of a liquid standard, but elaborated the idea until he produced the apparatus of which the following is a description, and which he has since patented.

The invention, which Mr. Wilson terms a chromometer, consists of two tubes of equal length (those used in the examination of petroleum being preferably of glass 16 inches long by $\frac{7}{8}$ inch internal diameter, and encased in brass tubing), marked *a a* in figs. 1 and 2, attached side by side to the hinged lid of the box which encloses them when the apparatus

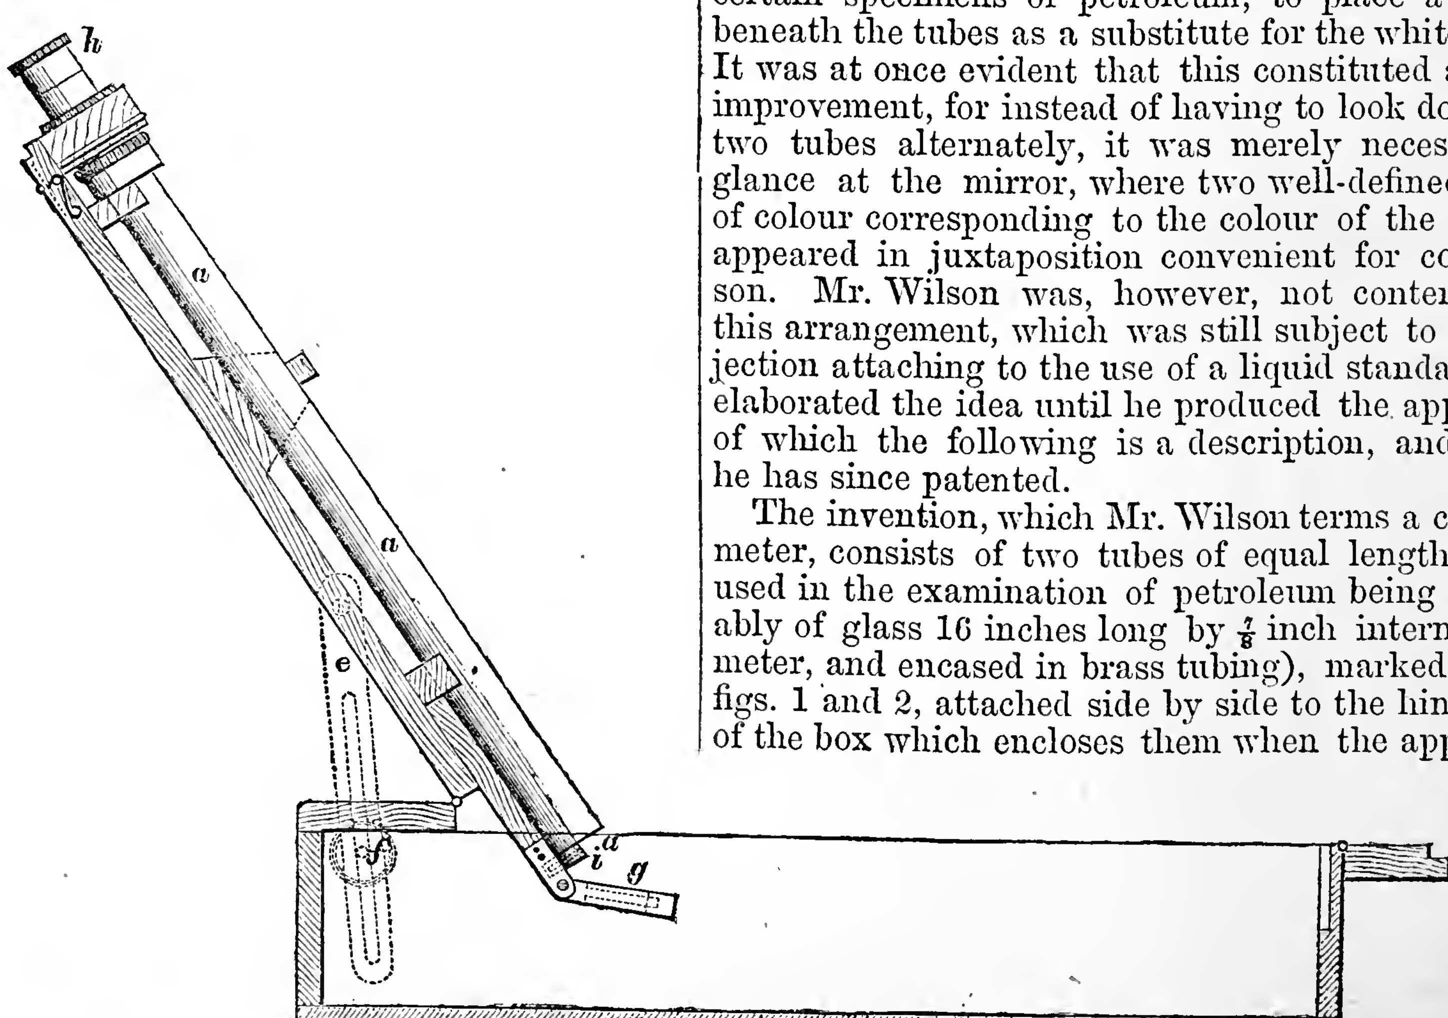

Fig. 1.

is not in use. The tubes are provided at both ends with screw-caps or end-pieces with glass centres (the caps at the lower ends being merely for convenience of cleaning), or the lower ends may be closed with circular plates of glass cemented on; and as it is essential to the proper transmission of light that the tubes shall be quite filled with liquid, the end-pieces are constructed as shown in fig. 2, where they are

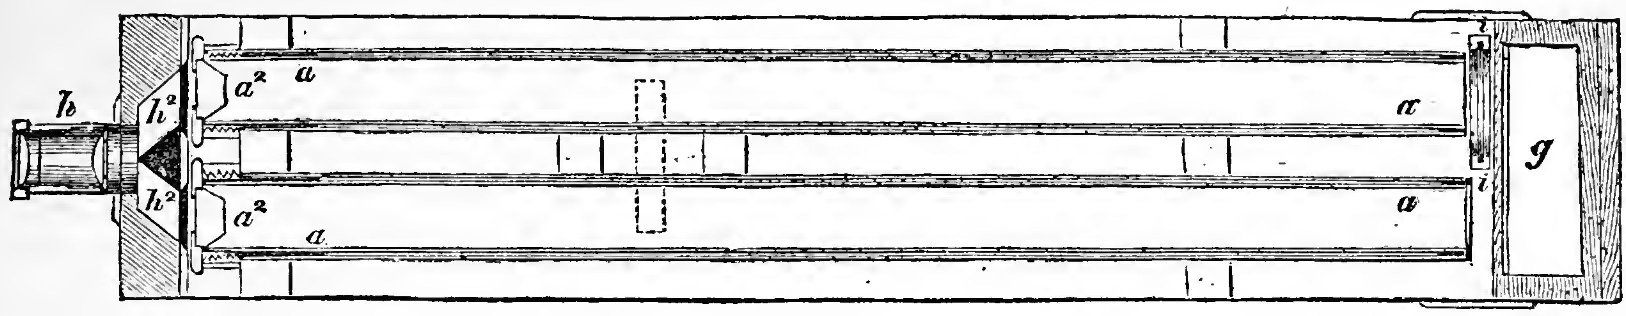

Fig. 2.

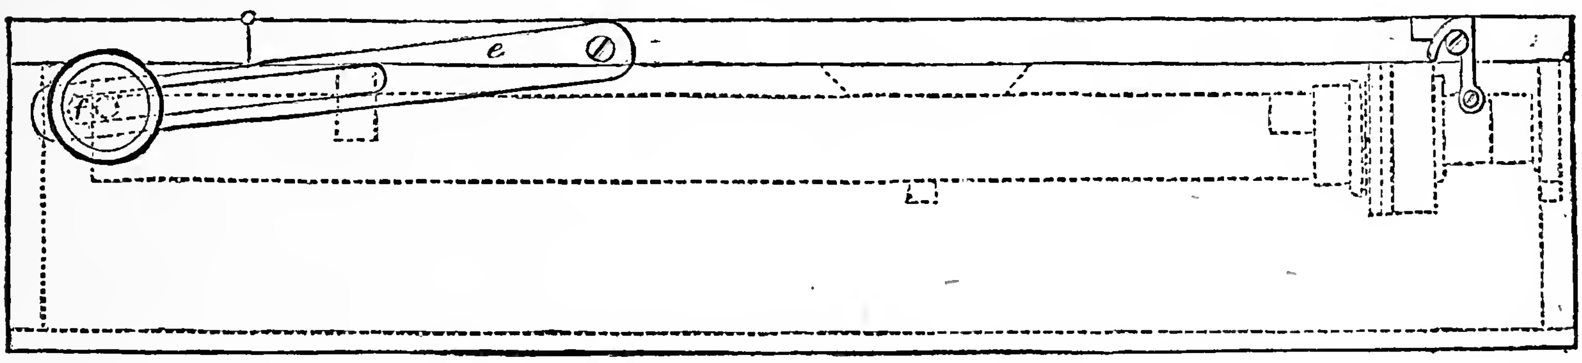

Fig. 3.

marked a^2 a^2, and where it will be observed that the glass centres are of considerable thickness. With this arrangement it results that any small quantity of air remaining in the tubes after they have been filled with liquid, must be displaced by the glass centres and forced to occupy the space round the bevelled edges of such glasses where its presence can cause no inconvenience. At the lower end of the tubes a small mirror *g* (figs. 1 and 2) is hinged

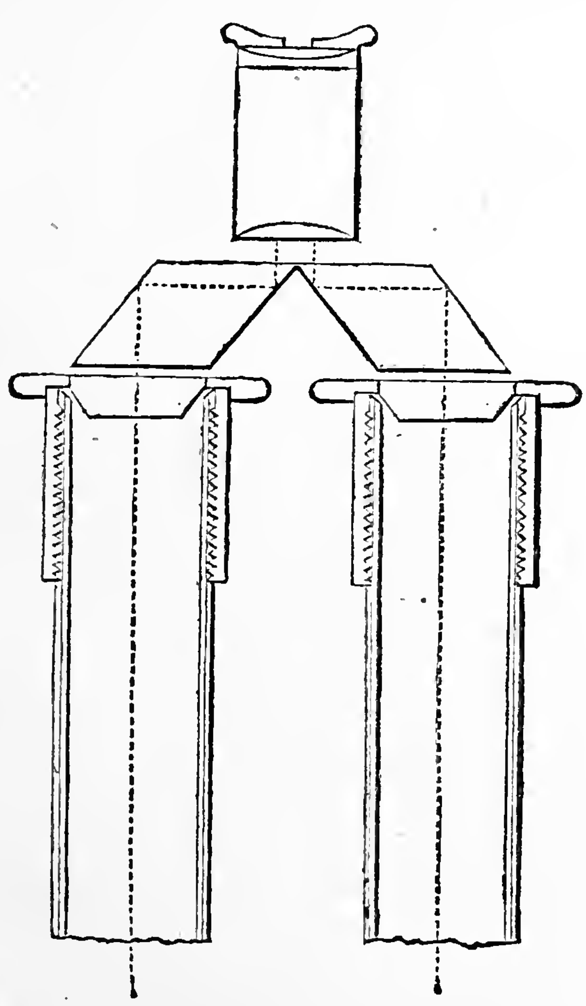

Fig. 4.

to the lid of the box, and at the opposite end is attached in similar manner an optical arrangement consisting as shown in figs. 2 and 4 of two double prisms, and an eye-piece (the eye-piece and prisms being marked in fig. 2, *h* and h^2 respectively).

So much in reference to the principal features of the apparatus which, as shown in fig. 3, appears when not in use as a box 20 inches by 5 inches by $4\frac{1}{2}$ inches, and is therefore portable and not liable to injury. Now for the mode of using it.

We will, in the first instance, suppose that our standards, with which we wish to compare certain samples, are liquid; accordingly we open the lid of the box, adjusting it at an angle of about 45°, by means of the link and set-screw *e f* (figs. 1 and 3) and place the apparatus so that the mirror *g* may receive the light through a window direct from the sky. We then fill either of the tubes with one of our standards, and the other tube with one of our samples; and applying an eye to the lens, we adjust the mirror so as to obtain the greatest amount of illumination. The rays of light reflected from the mirror take the course shown by the dotted lines in fig. 4, and we now observe in the lens a circular field divided down the centre by a perpendicular line. The tint of each semicircle corresponds to the colour of the liquid in the tube beneath it; and it is clear that we have here a means of comparing with great convenience and accuracy the two shades of colour. But, as has already been stated, the use of a liquid standard, at any rate in the case of petroleum, is open to objections; and Mr. Wilson has accordingly procured discs of stained glass about an inch in diameter, which when placed in the grooved holder *i* (figs. 1 and 2), the tube above being of course empty, produce exactly the same coloration of the corresponding side of the field, as if the tube were filled with the standard represented by the disc. The apparatus having been adopted by the Petroleum Association, discs have already been made, corresponding in colour to the standards of the Association, and petroleum standards of colour may now be carried in the pocket like so many halfpence.

As remarked at the commencement, this article refers particularly to petroleum, the desirability of having a better means of estimating the colour of this liquid having led to the invention; but the apparatus is without doubt capable of application in indicating the colour of potable waters (longer tubes being made use of), and in many other similar cases which will present themselves to the mind of the practical chemist.

85, *Gracechurch Street, London, E.C.*

EXPERIMENTS MADE FOR THE PURPOSE OF PRESERVING RAW MEAT.

BY DR. BAUDET.

Since I had obtained, by a lengthy practice, some considerable experience as regards the antiseptic and preservative properties of a substance which I term *spyrol* (carbolic acid), for being applied to the tanning, tawing and currying operations, I felt induced to try some experiments as regards the use of that body for the preservation of meat.

First process: *By immersion in phenic water at from* 5-10,000 *to* 1-1000.—On the 18th of October last year I took four wide-mouthed stoppered bottles, and placed in each 250 grms. of raw horseflesh, slightly moistened with phenicated water in the following proportions:—No. 1, solution at 4-1000; No. 2, solution at 3-1000; No. 3, solution at 2-1000; No. 4, solution at 1-1000. To the contents of every bottle I added a few small pieces of well-burnt charcoal, with the view to absorb any gaseous matter which might be evolved from the meat; after having hermetically closed the bottles, I have kept these for thirteen weeks in a room constantly heated at from 15° to 20° C. On inspecting the bottles after the lapse of time just mentioned, I found that the liquid which covers the meat had in all bottles become slightly rose-red coloured. The state of the meat, on examining it, was found as follows:—No. 1. The meat had become somewhat blackish-coloured, but was not spoiled at all. No. 2. Meat very well preserved, colour light rose-red. No. 3. Meat perfectly well kept, with the natural colour of fresh meat. No. 4. Meat has quite well kept; its colour has greatly improved, considering that raw horse-flesh is naturally deep-coloured. A few days after having inspected and noted down, as described, the contents of each bottle, I have taken a portion of the meat of No. 3 bottle, and, without having it washed or drained, have fried it, and dressed as a beefsteak; on partaking of it, in company with several other parties, we found the meat excellent, having only acquired a slight taste similar to that of cured ham and bacon, but by no means disagreeable. I have kept at the same temperature as indicated above, and under the same conditions, the meat in the bottles, well-closed, and have not observed, up to the middle of February last, any other change in the meat than an external drying and shrivelling up, and deeper colour, but internally the natural colour remains. From the foregoing experiments I conclude that phenicated water in the proportion of from 1-1000 to even 5-10,000, might be applied to keep raw meat fresh and sweet, without imparting to it either any perceptible smell or taste, provided the meat be kept in well-closed vessels, be they casks, tinned iron canisters, or other vessels.

Second process: *By means of vegetable charcoal coarsely broken up, and saturated with phenicated water at from* 5-10,000 *to* 1-1000.—This process is applied as follows:—I cover the meat with a thin woven fabric, in order to avoid its direct contact with the charcoal, which might penetrate into the fibre of the meat, which is placed next into barrels, care being taken to place therein first a layer of the phenicated charcoal, then a layer of meat, and so on alternately, until the barrel is quite filled, and all interstices properly taken up by the charcoal. As regards the importation of raw meat preserved by this method, from South America, I would suggest that the meat, first covered with any thinly-woven fabric, be placed in bags made of raw caoutchouc, very abundantly obtainable in the country alluded to; so that the importation of raw meat and the importation of caoutchouc might go, as it were, hand in hand. The mode of filling in alternate layers of phenicated charcoal and meat would, of course, remain the same; and there would be no difficulty of hermetically sealing up bags made of caoutchouc, either by soldering the seams together, or by placing a cap of caoutchouc over the mouth of the bag, and soldering the cap on hermetically.—*The Drug. Circular and Chem. Gaz., August,* 1871, from *Moniteur Scientifique.*

INAUGURATION OF THE NEW COLLEGE OF PHYSICAL SCIENCE AT NEWCASTLE.

The new College of Physical Science at Newcastle-upon-Tyne was inaugurated on Wednesday, October 24th. The college has every prospect of great success. The funds are ample; there are already a considerable number of students, and the appointments of the professors have given the greatest satisfaction. They are Professor Herschel, B.A., Professor Aldis, M.A., Professor Page, LL.D., and Professor Marreco, M.A. In addition to the chairs occupied by these learned gentlemen, it is proposed to establish a chair of history and political economy. The chair was occupied by Sir William Armstrong.

The Dean of DURHAM said the occasion on which they met was one both of satisfaction and hope to Newcastle and the neighbourhood. It was a matter of satisfaction that in little more than six months after a scheme for a college of scientific teaching, with a special view to the wants of the north of England, was proposed, they had been enabled to begin an effective course of instruction; and it was a further gratification that their plan had been understood and responded to by those for whom it was designed, so that they were not in the rather awkward position which had sometimes been the lot of similar institutions at their commencement, of having professors but no pupils. He would endeavour to place before them that day something of an estimate of the place which physical science ought to hold in a good education for the upper and middle classes, particularly in a part of England whose wants were somewhat peculiar. If he wanted to define a good education, he should say that it consisted in two things,—first, in drawing out and disciplining the powers of the mind so as to make it do our bidding in our coming life, and at the same time in imparting along with this power a considerable amount of valuable information. Now, on the first of these points—the discipline of the mind—a great deal might be said for the study of language. Language rightly used was a kind of mental logic; it trained the young mind unconsciously in accuracy of thought and in power of expression, and as we got older its higher studies introduced us to those great works of the Greeks and Romans which, for beauty both of thought and words, had never been equalled. The greatest English minds, and the best character of English thought, had been formed since the Reformation by two things, the Bible and the study of the classics; and those who believed that this character, and all the history which has been its result, had been inferior to none in Europe, would never be disposed to give up the great works of the old world as one most powerful instrument of education. At the same time, he could not deny that these studies had been, and still were, carried on in an absurdly exclusive fashion. The fact was that in all our schools, public or other, we needed far more division of work, or what our neighbours in France and Germany call a "bifurcation" in this matter. We may give our boys pretty much the same general education up to thirteen or fourteen, but then let them "bifurcate"—some keep to their languages, and others go off to a school of natural science, according as the boys' strong propensity or the insight of an able master should direct. He should say, generally, that the advantage to the mind of an education in physical science was (1) that it trained us to habits of close observation, of inquiry, of induction, and of verification; (2) that in doing this it brought us into close contact with the actual facts of nature; (3) that it had a direct bearing on our business in life, to an extent which was hardly the case with any other study. The first advantage of the study was that it trained the mind of the student to those rules by which all great discoveries have been made; it made him insensibly familiar with the course of inquiry by which he might in very truth "interrogate nature," and it gave him a large knowledge of that immense world of material truth which nature could reveal. And in saying this, he had almost anticipated the second advantage which he attributed to this study, that, in a manner quite different from any other, it brought us into such direct contact with facts. Other sciences, mathematics for example, which were so essential, both as a basis for nearly all physical inquiry, and also as a means for proving and completing discoveries, are simply a source of argument and of deduction. The mathematician starts with a few obvious propositions, and the rest of his work consists in drawing deductions from these. This training was infinitely valuable; and it was especially valuable in physical science on this account—not merely because it so wonderfully strengthened the attention, and enabled men to carry in their heads long trains of argument and of calculation—but because it showed that physical science rests upon the highest laws of reasoning, and that we can only master it by vigorous and systematic training. But then, this training once gone through, the student of physical science must, as it were, grapple with nature itself, and very little he would ever know of it unless he could do its work for himself, with his own hands and with his own eyes. And this, by the testimony of all scientific men, it was important to impress upon the minds of students at the very outset. They would never know anything of chemistry unless they did good work in the laboratory. It was only by examining for themselves fossil after fossil that they could know anything of the structure of the earth. There was one other point, which perhaps he ought not to have reserved for the end. It was the practical value of these studies and their bearing on some of the most important professions in the country,—it was how far they would assist the student in "getting on." Now, he assured them he was far from undervaluing this very telling and eminently modern and permanently English view of the question. He was not sure that the eagerness for immediate results did not sometimes overshoot its mark; and he suspected that often the man who had spent two or three "unproductive" years in gaining a really profound acquaintance with his profession, whether as a lawyer, an engineer, or a clergyman, in the end turned out the more successful man. It was quite true that, in the North of England especially, the native energy and talent of our great miners and engineers, aided by unequalled natural advantages, had placed them almost at the head of the enterprise of the world; but they were too sagacious not to be aware that in days of keen struggle, they could not hold their own unless they could enlist the most tried and educated workmen on their side. They were too well aware that in many branches of labour, of everything especially which had to do with art—of the composition of colours, for instance—they were surpassed by foreigners already, and he would add, to take a more limited though still a just view of the question, they, whose children were about to embark on those great professions, knew that their best chance, and far their noblest course, would be by attaining a thorough scientific mastery of the work they would have to do in life. They had heard what his notions of a good education were, and that they were far from being limited to the teaching of physical science. He hoped that literature would soon take its place in their classes, and there was nothing which would more rejoice him than to see the early foundation of a Professorship of English History and of Political Economy.

A luncheon was afterwards served in the Central Exchange News Room, to which a large number of ladies and gentlemen sat down. When the usual loyal toasts had been drunk,—

Earl Grey proposed "Success to the Newcastle College of Physical Science." His lordship remarked that the College was intended to give sound instruction in the principles of physical science to young men who for the most part would in future life take an active part in the various industrial enterprises for which the district was distinguished, and who would be the main assistance in carrying on the mining operations, shipbuilding yards, engineering, chemical and other great works which were in operation in the town and neighbourhood. It was therefore highly desirable to give them such sound instruction in the principles of physical science as would enable them so to join science with practice as to afford them a far better chance than they ever possessed before of making advances in the industrial pursuits of the district. They knew what great improvements had been effected in the various departments of industry which distinguished this neighbourhood, in the past thirty or forty years, and it was reasonable to hope that when there were employed a much greater number of persons who not only knew from practice and from experience how they ought to be carried on, but who were also instructed in the principles of science upon which all improvements proceeded, the career of improvement would proceed with accelerated speed. The College was intended to increase the knowledge of the most effective mode of applying the powers of nature, and was calculated directly to improve the condition of every man in the country; because they must consider how, by the beneficial action of commerce, improvement in any one branch of industry contributed to the advantage of all. No doubt when great discoveries and inventions were made, those whose enterprise and skill and knowledge had achieved the improvements obtained the first and largest reward; but it was impossible in the nature of things that the reward which they derived from their exertion should not extend to the community by whom they were surrounded. It was the world at large which benefited by the improvement in physical science, and it was the advancement of physical science that the College was calculated to promote. But though that was a tempting field for discussion, it was far too extensive for him to enter upon at that time, and he could only say that while the College was most deserving of their support upon the grounds which he had stated, the toast of success to it was most fittingly coupled with the health of Sir William Armstrong. The name of Sir William had a European, or rather a world-wide celebrity for the success with which he had applied physical science to useful productions,—not only in regard to those fearful instruments of destruction with which his name was so closely associated, but what was, he felt, of far more importance, to a variety of machinery and contrivances of the utmost value for supplying the wants of mankind. The example and success of Sir William Armstrong were the strongest encouragement that could be given to the youth who would attend the College which had now been founded.

The toast was drunk with great enthusiasm and with all the customary honours.

The Chairman, in responding, said he felt great difficulty in reconciling the prominence of his position at that table with the absence of prominence in the services which he had rendered to the institution which had that day been inaugurated. He was but one of a large committee which had devoted its labours to the promotion of the undertaking, and whatever thanks were due in respect of those labours were due to the committee jointly, and not to himself individually. He, therefore, in the name of his colleagues, thanked them for the good wishes which had been manifested towards the institution which had been the object of their care. He trusted that the example which had been shown in Newcastle in regard to the establishment of that college would be rapidly followed in all other important towns in the country; for he was satisfied that it was only by scattering local colleges over the whole land that they could hope to effect that widespread diffusion of scientific knowledge which was so essential to the advancement of the nation in a moral as well as an intellectual point of view. That object would not be effected by great national scientific colleges; but only by bringing scientific instruction to the doors of the people. They must enable them to have it at home, and not allow them to be any longer deterred from seeking it by the great expense and inconvenience of travelling to distant places. It was surprising how little had yet been done in the way of spreading scientific knowledge among the people of this country. It was very different on the Continent; and had scientific instruction not been confined, as it had been, to a few persons, we should have had a vastly greater amount of practical and beneficial results arising from the application of science than we had actually experienced. The value of scientific education was held in far higher estimation on the Continent than in England. Its value had been fully recognized by all those nations who were our rivals in industry, and it was clear that the greater diffusion of scientific knowledge among those nations had been the principal cause of the more rapid progress which had been observable in their industries than in our own. We were far more ahead of our rivals twenty years ago than we are at the present day, and unless we awakened to the necessity of improving our condition by the promulgation of science, we might expect to be rapidly overtaken. Our rivals are already close upon our heels—closer than was generally admitted in this country, and it ill-behoved us to slumber in fancied security. He hoped, then, that the college which had just been inaugurated might tend to avert that danger, not only by its direct local effect, but by leading to the establishment of several similar institutions in other parts of the country.

THE RELATION OF MINERAL OILS TO FIRE.

The following letter by Professor Atttfield has recently appeared in the *Times*, and the subject it refers to is one deserving the special consideration of chemists throughout the country:—

"The awful conflagration at Chicago was started by a boy in a cowshed. He took with him a mineral oil lamp, which the cow kicked over. Accepting this statement of the origin of the fire as true—and the frequency with which fires are kindled, afloat and ashore, by the new mineral oils is unquestionable,—what conclusions should be drawn and what lessons learnt? Nay, to ask a more practical question, how does the public stand respecting knowledge and ignorance on the subject of fires? That some substances are combustible and others incombustible, that some combustibles burn more readily than others, and that any combustible material catches fire sooner under certain conditions than it does under others, are facts well and widely known and insensibly acted on by us in the management of households, warehouses and such structures. We rightly allow only metal and air to be in immediate contact with our domestic fires and flames, we take more care of gas and spirits than we do of candles and coals, and we know that curtains hanging from a pole are far more easily fired than curtains folded and stored. To wilful or thoughtless neglect of one or more of these points is most generally to be traced the cause of a fire; but not always. A person may have occasion to handle a material of whose relation to fire he is ignorant; or, knowing that the thing handled is combustible, a man may be ignorant of its relation to other combustibles. This latter is the present position of the public, abroad as well as at home, respecting those mineral oils which during late years have been so largely used for illuminating purposes, and which now and again cause fires of lesser or greater magnitude. The degree of inflammability of colza and the other old vegetable oils is fairly well known. They cannot easily be fired, except on a wick, and even then a flame must be applied carefully and for some little time. On the other hand, everybody who uses them knows that common spirits and naphtha catch fire in a moment; these, therefore, are handled, stored and employed with adequate precautions. But the mineral oils, though much nearer to spirits than to the old oils in their degree of inflammability, are treated by the public as though belonging to the latter class. The mistake could not well have been avoided; for these mineral liquids are more closely allied to oil than to any other class of fluids, they are used in the place of oil, and hence have come to be sold by oilmen and purchased by consumers under the name of oil. Doubtless the public will in time learn that in relation to fire these substances are of a spirituous rather than an oily nature. We may then expect that fires started by mineral oils will result from carelessness or wilfulness, and not from ignorance. Meanwhile Parliament, the Press, men of science, and oil traders must do their best to contribute to the removal of this ignorance. Parliament has already done something, and promises to do more. It is now in Great Britain illegal to sell the more inflammable kinds of mineral oil, properly termed petroleum spirit and paraffin spirit, unless every vessel is labelled as follows:—'Great care must be taken in bringing any light near to the contents of this vessel, as they give off an inflammable vapour at a temperature of less than 100 degrees of Fahrenheit's thermometer.' But petroleum oil, as at present sold in England, gives off inflammable vapour at temperatures very slightly above that just stated. Paraffin oil is less inflammable than petroleum oil, but both take fire with the utmost readiness compared with olive, sperm, colza, and the other vegetable oils. I would implore petroleum merchants and oil dealers generally to endeavour to import and supply petroleum oil which shall be less instead of more inflammable than paraffin oil. From my own experiments and experience I venture to assert that this could be done without injury to the illuminating power of petroleum, and, if effected gradually, without the slightest risk of the British paraffin oil driving the American petroleum oil out of the market; indeed, I am of opinion that public confidence in petroleum would be so much increased that a still larger trade than ever would be carried on in that important article. The Government has undertaken to amend the Petroleum Act next year, more particularly as to the way in which the inflammability of the vapour of the mineral oil is to be ascertained. Perhaps the cause of public safety from fire would be usefully served by the insertion of a clause rendering obligatory the employment of a caution-label on all vessels containing any kind of mineral oil, the label of the present Act serving as now for petroleum spirit and paraffin spirit, and one drawn in simpler and less alarming terms for petroleum oil and paraffin oil.

"From the whole matter the public must conclude that its present position respecting the relation of mineral oils to fire is one of ignorance, and therefore of danger. The sooner this ignorance is dispelled by enactments of the Legislature, full discussion in the Press, and the occurrence of fires, which, let us hope, will never again approach the fearful nature of that in Chicago, the sooner shall we arrive at a time when fires kindled by mineral oils will not be more frequent than those started by other combustible substances. That they are more frequent I think no disinterested person will venture to deny."

The Pharmaceutical Journal.

SATURDAY, OCTOBER 28, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

POISON LABELS.

So much has been said of the notice taken of the poison question by the general press, that it seems desirable to place before the readers of this Journal any comments that may from time to time appear in the London or provincial newspapers. Through the courtesy of a correspondent we are enabled to reproduce, from the *Carlisle Express and Examiner*, the following editorial article upon the case of poisoning reported at page 355. The article is evidently written in a spirit of fairness that we should be glad to see more generally manifested by those who discuss the difficult subject of accidental poisoning.

"The facts brought out at the inquest held in Carlisle on Tuesday last, upon the body of a child that had been poisoned by an overdose of syrup of poppies, possess an importance beyond the case which was immediately under consideration. That the child died from the effects of the poisonous drug was placed beyond question, and the medical man mentioned another instance which had come under notice recently, in which a child that was troublesome at nights had received his quietus in the shape of some narcotic of a similar kind. Mr. Parker, the druggist, stated that it was not a medicine that he recommended, and he denied having given any directions or advice at all in supplying the bottle last week; but it was certainly far from satisfactory for the jury to hear an experienced apothecary saying that a teaspoonful could be administered with safety, and a medical man of extensive practice asserting that such a dose was fatal to a child so young, and backing up that view by authorities of the highest standing. Such a collision shows clearly the wisdom of the Legislature in requiring that such preparations should all be labelled "Poison," so that those who use them may at least have something to remind them that death lurks in these 'drowsy syrups.' There are good grounds for believing that they are most extensively used among women who wish to save themselves the trouble of nursing; therefore, it is all the more important that the provisions of the Legislature should be carried into effect. The directions of the 'Sale of Poisons Act' (1868) are clear and emphatic. It is enacted, under a penalty, that 'it shall be unlawful to sell any poisons, either by wholesale or by retail, unless the box, bottle, vessel, wrapper, or cover in which such poison is contained be distinctly labelled with the name of the article and the word 'Poison,' and with the name and address of the seller of the poison.' Opium, and all preparations of opium or of poppies, are specifically mentioned in the schedule of the Act, and this inquest—which affords a good example of the value of those coroner's inquiries which some people would abolish—will, we trust, have the effect of reminding dealers in poisonous drugs of their duties and responsibilities."

This case is interesting, from the fact that it illustrates one of the difficulties involved in the application of the Pharmacy Act of 1868, viz. the question how far the use of the poison label should be carried as one of the precautionary regulations for preventing accidental poisoning.*

It has been maintained by many that the use of the poison label for paregoric and such medicines would be an absurdity; and we thoroughly agree with this opinion as regards very many of the circumstances under which paregoric is used. The same view might, perhaps, be taken in regard to syrup of poppies, were it not for the fact that this syrup and other mild narcotics "are most extensively used among women who wish to save themselves the trouble of nursing." Bearing this in mind, it does not seem an unreasonable opinion that "such preparations should all be labelled 'poison,' so as to remind those who use them that death lurks in these 'drowsy syrups;'" nor, apart from the misuse of these narcotics, can it be deemed a strained interpretation of the Act to include under its provisions for the use of the poison label a preparation that is capable of proving fatal to those for whom it is chiefly used.

We cannot, therefore, complain that our contemporary, referring to the "clear and emphatic" directions of the Act, expresses a hope that this case will have the effect of reminding dealers in poisonous drugs of their duties and responsibilities; but it must not be supposed that we also admit Mr. PARKER to be censurable in this case; for though the CORONER distinctly put forward the opinion that the Act rendered obligatory the use of the poison label for syrup of poppies, it must be remembered that the contrary opinion is held as decidedly by very respectable authorities. They would argue that in this case the poison label would not have prevented the death of the child, either because such a wide use of this label as to comprise syrup of poppies, paregoric, etc., would make that precautionary regulation ineffective by reason of its being so familiar as to be little heeded, or because of the bad habits, ignorance, etc., of the people using such preparations, or because of idiosyncrasy. There is, no doubt, some ground for each and all of these reasons being urged against the wider use of the poison label; but we believe that whatever cogency those reasons may have in this respect, they would be still more effective in support of the view that the sense of individual responsibility in a properly qualified pharmacist, no less than regard to self-interest, would afford the public security against the danger of poisoning by accident or misuse, far more effectually than the prescription of regulations which, in spite of the effort to make them specific and precise, are nevertheless open to diverse interpretation.

* Just as we are going to press we have received the report of another case of poisoning by syrup of poppies, which will be found printed at p. 356.

While speaking of this subject we cannot refrain from again mentioning the very frequent misunderstanding of the provisions of the Pharmacy Act in regard to the sale of poisons that is evident in the remarks of magistrates and coroners. Within the past month we have had to record no less than four occasions* upon which a censure has been passed, in terms more or less inappropriate, upon persons who have complied with all the requirements of the law.

It seems to be a matter worthy of the consideration either of the Privy Council or of the Council of the Pharmaceutical Society whether it would not be advisable to furnish all coroners and magistrates throughout the kingdom with information as to the present state of the law relating to the sale of poisons.

THE RELATION OF MINERAL OILS TO FIRE.

On another page we reprint a letter to the *Times*, in which the writer, Professor Attfield, refers the many conflagrations resulting from the incautious use of the different varieties of mineral oil to ignorance on the part of the public respecting the relation of these liquids to fire. The point of the communication is that paraffin oil and petroleum, being sold and used under the name of lamp oil, most consumers naturally treat them with neither more nor less care than would be observed with colza, sperm, and the old vegetable oils; whereas in the readiness with which they catch fire, and the facility with which they assume the vaporous condition, they more closely resemble spirit of wine or turpentine, and should be stored, carried and handled with all the precautions commonly adopted in manipulating these inflammable liquids. In such a serious matter it is, no doubt, desirable to endeavour to enlighten the public by all possible means, and pharmacists, who are rightly supposed to possess chemical knowledge on general as well as pharmaceutical subjects, may frequently have opportunities of contributing to so desirable an end. The existing and prospective legislation on this matter in Great Britain and America can only be excused on the plea that it is provoked by, and intended to counteract, the ignorance of the majority of consumers of mineral oil. Such notices by the newspapers as that to which we now allude also help in displacing this ignorance by knowledge. But we fear the object will not be fully accomplished until many more of these fires have occurred; for no facts are burnt so indelibly into the brains of John Bull and Brother Jonathan as those which cost them dearly. When science comes to be taught in schools, familiarity with the simplest first principles will go far to enable us to avoid catastrophes which arise from our ignorance respecting common things.

* See *ante*, pp. 257, 276, 298, 317.

On Wednesday next, November 1, the Evening Meeting of the Pharmaceutical Society will be held. On that occasion Mr. J. B. Barnes will bring under the notice of the meeting a new excipient for pills; Mr. J. E. Howard will make a statement concerning the examination of some cinchona-trees grown in India; Mr. T. Greenish will give some particulars as to pharmacy in North Germany, the result of inquiries made during a recent visit; and Professor Redwood will bring forward the subject of the substitution of proportional numbers for specified weights and measures in the description of processes in the Pharmacopœia. It is hoped that the audience will be a numerous one, and that many members who have not hitherto attended these meetings will endeavour to be present. The chair will be taken at 8.30.

Although it does not lie within the ordinary province of this Journal to call attention to errors into which, in common with their English brethren, Transatlantic editors sometimes fall, one paragraph has been going the round of the American newspapers that it is a great pleasure to be able to contradict. It seems to have been telegraphed to St. Louis during the meeting of the American Pharmaceutical Association; and the following, taken from the *American Journal of Pharmacy*, will serve as an illustration of the unlooked-for and unwelcome services sometimes rendered by the cable telegraph:—

"Obituary.

"Professor Robert Bentley.—During the late meeting of the American Pharmaceutical Association in St. Louis, a cable dispatch announced the death of this zealous labourer in the cause of science. The intelligence cast a gloom over the members who knew him by reputation or personally, and the sad event was feelingly alluded to by Mr. Henry B. Brady, a personal friend of the deceased. In the next number we shall lay before the readers a biographical sketch of the deceased."

We believe the error arose in the announcement of the death of Mr. R. Bentley, the publisher.

It is worthy of observation that the deficiency of sound education, so frequently apparent in the candidates for the Pharmaceutical Society's examinations, and which has for a long time and in various ways been under consideration, is not confined to Pharmaceutical students. The same lack has been met with in the Preliminary Examinations of the Royal College of Surgeons. With a view of bringing the subject prominently forward, Mr. Gay, at the meeting of its Council, on the 19th inst. gave the following notice of motion:—

"That the proportionately large number of rejections at the Preliminary Examination for the diploma of the College is a fact which demands the serious consideration of the Council; and that a Committee be appointed to consider the subject, and to report to the Council thereon."

At the London Institution the first Evening Lecture for the session 1871–72 will be delivered on Thursday, November 2nd, by Dr. J. H. Gladstone, the subject being, "Michael Faraday: the Story of his Life."

At the meeting of the Chemical Society, on Thursday, November 2nd, Mr. W. H. Perkins will read a paper on "Anthroflavic Acid."

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The opening Meeting of the session was held in Anderson's University on Wednesday evening, 18th inst., Mr. THOMAS DAVISON, President, in the chair. There was a good attendance of members. Mr. H. C. Baildon, President, and Mr. John Mackay, Hon. Secretary of the North British Branch of the Pharmaceutical Society, were also present, from Edinburgh.

The CHAIRMAN briefly introduced EDWARD C. C. STANFORD, Esq., Ph.C., F.C.S. (British Sea-Weed Company), who delivered the inaugural address as follows:—

Gentlemen,—As this is not the first time that I have been requested by your committee to open your session, I feel that, however inadequately and imperfectly I may perform the pleasing duty they have imposed upon me, I must, nevertheless, now look upon it as a duty, and one that can be no longer postponed.

I would have much preferred that some one of you should have occupied this position on the present occasion; one more conversant than myself with the numerous details of your most detailed of all professions; one who could have spoken with authority on those numerous vexed questions which are now becoming so interesting to all of you. You will not, however, expect me to enlarge upon these; I could add nothing to your information on such topics; and, moreover, I would select higher ground for our occupation this evening. It is always a relief to turn from those petty annoyances, which are inseparable from every man's daily life, to a larger field, where there is light and recreation. We are all allowed to soar aloft into the calm serenity of philosophic truth, where the little vapours of human disputes never rise and cannot penetrate. It is interesting even to observe from these thoughtful eminences the money-grubbers of the earth, and note their infinitesimal size and true value. Without, however, touching on vexed questions, I feel bound to say a few words about the Pharmaceutical Society. I have had unusual opportunities of intimately knowing for years the men whose names are only now becoming familiar to most of you. Through good repute and evil repute, mostly the latter, they have fought an uphill fight for many years against the ignorance and prejudice of this country. You cannot be sufficiently grateful to these disinterested men that they have at last won the position; nor can you ever sufficiently revere the memory of their intrepid leader who fell nobly fighting for the good cause. I say disinterested, because few of the founders of the Pharmaceutical Society could ever expect to reap the benefit of their labours in their own lifetime; they worked for the public good, and they worked for posterity. And let us not forget that the ignorance they fought against was largely developed in their own ranks. If you compare the state of British pharmacy when the Society was first founded with that of Continental pharmacy, and the status of the British pharmaceutist with that of the French pharmacien, you will see how much we had to be ashamed of and how much we had to learn. The pharmacien, a man of university education and of high scientific attainments; the pharmaceutist, a poor apprentice, who studied the "rudiments of chemistry" in the shape of pounding various drugs, and never cared to know from whence they were derived. The emblem of the one, the microscope and the balance; the emblem of the other, the pestle and mortar. The founders of this Society saw that it was no use to clamour for an equal position for their brethren until they were educated for that position. To have suddenly converted the status of the chemists and druggists of Great Britain to that of high-class pharmaceutists without education, would have been quite as sensible as to have made them all post-captains, and sent them to sea without teaching them navigation; though the former mistake might have been better for the British navy.

The Council acted wisely, therefore, in at once setting to work as an educational body. They established a school of pharmacy, chemistry, botany and materia medica. Fownes and Pereira, the most eminent men of the time, were the first lecturers, and their successors have fully maintained their reputation. There is no school in London where the teaching of these special sciences is so sound and so good. No greater proof of its success can be desired than the comparatively large number of young men who have passed the curriculum, whose names are already well known in pharmacy. So far from being the last in the race, there is every probability that the present race of pharmaceutists will not be excelled, and may even be unequalled in any other nation. Now, however, that the Pharmaceutical Society is an examining body, and the only one under Government by which all future pharmaceutists will have to be examined, their position has certainly become anomalous, and they must sooner or later sever this connection. They will have to renounce the right of educating and then examining; the examination must be restricted to their rules, but the education must be open and free. London, as the great heart of the United Kingdom, will always be the centre; and the eminent professors who have made the reputation of Bloomsbury Square will, I trust, long guide the helm of pharmaceutic education. But every large city must become another centre for the education of its own district. You are particularly well situated here, as almost any kind of scientific education can be cheaply obtained in this city. It is time to be up and stirring. I cannot congratulate you very heartily on your remarkable progress in pharmaceutic elevation so far; but you are earnest men; and if *festina lente* is your motto, it is a good one, if you do not allow the second word too much to disqualify the first. There is no doubt your action has been a good deal paralysed by the very large number of surgeons who keep open shops here; in fact, I never saw any city so peculiarly situated in this respect. The public have a right to expect that all assistants in these shops should pass the examinations of the Pharmaceutical Society. The evil will not, in my opinion, be a lasting one, for I am convinced the public welfare demands a rigid separation of medicine, surgery and pharmacy, as in France, and to that it will come sooner or later.

Any man who wishes to become eminent in either of these branches of science (and all students ought to endeavour to be so) will find that he has the work of a long lifetime before him; and to suppose that pharmacy can be learnt, in its true sense, in the short course presented to medical students is perfectly absurd. The fact really is, that pharmacy, materia medica, and chemistry and botany in their relations to it, were almost unstudied sciences in this country, and there were no examinations, worthy the name in either before those of the Pharmaceutical Society were established.

Another effect of stringent examination will be to considerably decrease the number, and largely increase the intelligence of those entering the profession. Both these effects are improvements; but the latter involves another difficulty. Where are the masters who can teach the apprentice of the present day the theory of his profession? Not until the old school has passed away can we expect to find masters generally sufficiently qualified to teach the apprentice all he requires to know to enable him to pass the examinations of the Society.

I am very glad to see, from the last report of your committee, that they are already up and doing; that they know the wants of their brethren, and are determined to supply them, wisely and well. It must also be a satisfaction to all, that one of your oldest members should now represent you at head-quarters. The London Council is much the better for the shrewd common sense so characteristic of its Scotch members.

Perhaps even some of my present audience would not care to pass a stringent examination in thermal equivalents or the primordial utricle. Nor can we expect the masters, who really are well posted up, to devote so much of their time as would be necessary to thoroughly teach such things.

It, therefore, will always be necessary that the apprentice of the future should have access to local schools, and that a certain portion of his time shall be devoted exclusively to the study of the science of his profession. This will, of course, demand some concession on the part of the masters in shortening the hours of labour; but as we get older we are beginning to find out that it is not necessarily those who work the longest that do the most work. We are beginning to measure a man's life not by its length, but by the work he has done. In all directions, in every trade, business and profession, there is a growing tendency to shorten the hours of labour. It is a movement with which I heartily sympathize; because I believe it increases the health, and therefore increases the available work of our race. It is astonishing to me that men who feed and rest their horses when they want to get work out of them, and where they only want muscle and strength, will allow, and even expect, their poor human drudges to wear out their minds and bodies in continual work. This is a digression, but I mention it here as a sign of the times, and one which will surely act to shorten even your hours of labour. Higher remuneration, shorter hours, and raised social position for you all, must be the result of the arduous labours of the founders of the Pharmaceutical Society. I cannot leave this subject without congratulating you on the wonderful success of the Pharmaceutical Conference. With the Edinburgh Meeting fresh in your recollection, I need scarcely remind you of the value of its meetings, nor of the extremely social and real science to be found among its members. The few who met the first year at Newcastle could scarcely have expected that by this time we should number nearly 2000 members, and publish a most valuable year-book.

Let us now take a rapid glance at some of the extraordinary advances that the last few years have seen in pharmacy. It is impossible to predict what may be the results of a more extended knowledge of chemistry in its application to medicine. But we may confidently anticipate that remedies will be found to alleviate all human suffering; and that all sickness may become curable but that of old age, for, unlike the ancient alchemists, we except this ailment as beyond human power. What does not mankind owe to the discoverer of chloroform? Reckon up the sum total of lives saved and suffering alleviated, and tell me, if you can, the value of that discovery. Again, following the germ-theory of disease, how enormously has the external use of carbolic acid as a germ destructive increased the surgeon's power to save the limbs and the lives of his poor patients. What would medicine do now without morphia, quinine, strychnine and the other alkaloids, the extraction of every one of which, from their natural sources, has been an elaborate chemical study and a triumph in itself? Who can define the limits of such inquiries? We have every reason to expect that some, perhaps all of these complex bodies will some day be produced artificially in the laboratory. The masterly researches of Dr. Wright, on the substitution products of morphia and codeia, certainly point in this direction; while the preparation of artificial quinine has been as long looked forward to as was the "elixir of life" and the "philosopher's stone" in former times. It is remarkable that researches of this nature, if unsuccessful in attaining the object in view, are invariably fruitful in other discoveries. It was, I believe, in researches to test the possibility of making artificial quinine, that Mr. Perkin made his wonderful discovery of mauve,—a discovery which has laid the foundations of a gigantic industry of such rapid growth that it has revolutionized in a few years the colours of the world. So the late Dr. Matthiessen, in his research on morphia, obtained apomorphia, another base differing from the former only by an atom of water, and yet having such totally opposite properties that it is the most rapid emetic known.

Recently, another substance of vegetable origin, alizarine, has yielded to the persevering attacks of chemists, and is now manufactured largely, and in many instances it supersedes, and in some respects is finer than, the natural colour. It is worthy of remark that this new colour, like those from aniline, is a product of coal-tar, being derived from anthracene, one of its constituents, discovered by Dr. Anderson. It is a remarkable fact, and worth reflecting on, that as we extract our light and heat from coal, the buried light and heat of the sun collected ages ago, so we are now enabled even to split up the buried rays into all their component colours and print them indelibly on our fabrics. This is not a figure of speech, but an actual fact.

There is little doubt that indigo, another vegetable colour, will not long hold out against the determined synthesists, who will ere long succeed in piecing it together; indeed, the discovery is already announced. Think, also, of the numerous odours and flavours chemistry has given us,—the subtle ethers, which render the flavours of our choicest fruits even more perfectly than they could be obtained from the fruits themselves. As one example only of an odour, take nitro-benzol, now so enormously used to give an almond flavour to a scented soap, at a cost within the reach of the poorest of our population.

The increasing use of bromide of potassium, another of chemistry's contributions, would have been impossible, were it not for the extraordinary discovery of an apparently evaporated sea-water bed in Germany. The amount of bromide consumed in medicine is now enormous, and most of it is derived from this source. The same mines have also completely changed our sources of potash; they produce far more than all the other sources of England and France put together, and have so reduced the price that carbonate of potash is now largely made in this country at a price which competes most favourably with American pearlash and will ultimately drive it out of the market. Bromide of potassium is an instance of a substance long used in medicine before its valuable properties were discovered.

One of the most remarkable chemical contributions to medicine is chloral hydrate; the rapid increase of the use of this substance is so extraordinary, that I know of one firm alone which disposes of 1000 lb. per week, and this is probably not half the consumption. It is certainly, after chloroform, the most curious selection from the laboratory of organic research, in its effects on the human system. I would venture to remark here that I hope Germany will not always supply the most of such preparations as this and the vegetable alkaloids. At present, no doubt, they have a large advantage over us in the manufacture of these substances where much spirit is required, from the extravagant price of duty-paid spirit here. Methylated spirit cannot always be used, and, moreover, it introduces impurities. It has always appeared to me that our Government should have gone further, and allowed the use of pure spirit duty free for manufacturing purposes; the use of such would have secured the admission to the works of excise officers, who could prevent any abuse of the privilege. It is admitted that methylated spirit can be made potable, and our local shebeens and police courts can testify to its value as an intoxicant. Indeed, if our whisky shops were restricted by law to the use of pure methylated spirit, we should cease to hear of the maddening effects produced in our streets by vile drinks of unknown composition. Pepsine and pancreatin deserve a passing notice,—these curious fermentive principles are now largely used to assist nature in the process of digestion. That these principles are identical with those secreted in the human interior, there is little doubt, but that they really have the large effect in the presence of the living stomach that is claimed for them, is, I submit, open to doubt.

Perhaps the most important of all technical chemistry is the utilization of waste materials; and, fortunately, it has been of late years greatly progressive. The history of large chemical works is generally that each accumulates enormous stocks of some waste material, which at last becomes such a nuisance that the owners are compelled to adopt some means of working it up. The process invented for the purpose of ridding ourselves of a nuisance often turns out a source of profit; such, for instance, are the utilization of soda-waste by Mond's process, and the recovery of manganese from waste still liquor by Weldon's process. Deacon's new process for the preparation of chlorine from hydrochloric acid by dissociation, bids fair, however, to supersede the use of manganese altogether. The manufacture of soap, too, is likely to undergo a considerable change if Professor Morfit's method of combining the alkali as carbonate direct with the fatty acid, and superheating to free the carbonic acid be generally adopted. The process is a very perfect one, and the soap can be made and finished in a few hours.

I wonder what Sir Humphry Davy would have said to any one who talked about stellar chemistry. That great man, in ridiculing the idea of lighting London with gas, triumphantly asked the fanatics who proposed such a wild scheme, whether the dome of St. Paul's was to be the gasometer? Yet we cannot imagine Regent Street illuminated, or rather darkened, with dips again, and to us stellar chemistry has a real meaning. Who will venture to bound a science which reaches far away through space, and with unerring accuracy tells us the composition of distant worlds and distant suns? What can be more humiliating to our small intelligences than the reflection that a distant star will photograph its spectrum on a sensitive surface with the ray of light that left it when the oldest man in this room was a boy? What would the great father of British chemistry have said had he stood in the lecture-room of the Royal Institution, where his great discoveries were made, and seen the burning hydrogen extracted by your great countryman Graham, from a meteorite, the heat and light of another world? or could he look with Lockyer on the burning flames of hydrogen, which dart up from the sun a height of 50,000 miles; or could he read the flashing telegrams which run so rapidly round our world, that all our notions of time are completely upset, and we actually receive intelligence to-day which was sent to-morrow? Excuse the apparent absurdity, it only shows how powerless language is to keep up with human progress. Could he have lived with us and seen a large city dependent entirely for its communication with the outer world by a marvellous kind of photography, so minute that it enabled a pigeon to carry a proof-sheet of the *Times* under its wing.

Could Sir Humphry Davy now stand in our favoured position and see all these advances, he might, indeed, admit with Newton that he had simply played as a child on the seashore, while the great ocean of truth lay unexplored before him.

In technical pharmacy, what advantages are now given by the use of steam and gas! Steam, gas and water enable us now to carry out preparing processes which were impossible before their introduction.

Coffey's curious application of high temperatures in stoneware by convection or circulation of highly heated paraffin oil well deserves attention; it may be found specially useful in evaporating some of those corrosive liquids which can only be heated in stoneware vessels, the heating of which is always difficult.

I am glad to notice some recent improvements in tincture presses,—no apparatus is more susceptible of improvement; there is great need of a small economical hand-press, which would combine the strength of the hydraulic press with the sustaining power of the screw, and need little attention. Two presses lately described in the PHARMACEUTICAL JOURNAL appear to me important improvements.

Some improvement ought to be made in our measurement of doses; a drop, a teaspoonful, a wine-glass, are terms far too indefinite and various to be always employed in the administration of medicine, and we shall owe much to the inventor of a better system—a worse would be difficult to obtain.

No study can be more interesting than materia medica; to know the history of every substance that passes through the hands of the pharmaceutist adds an interest to his work, which must be felt to be understood. Every day, from all quarters of the globe, are new medicinal substances coming forward; perhaps we even too much neglect the valuable productions of our native soil.

Acclimatization of plants is being largely studied; several plants are on their trial in India and some of our other colonies. Of course, as in chemistry so in materia medica, the interest centres in quinine. A quinine famine is a thing we dare not think of, the idea is too horrible. The Indian Government cinchona plantations are flourishing, and we may expect them some day to be our chief sources of supply, if, meantime, the laboratory does not rise up in competition with them.

There is a large field open in this country to the patient student, in the effects of soil, culture and climate on medicinal plants. Any one in the country with command of a small garden, would be amply repaid by making this his study. There is a large range of most valuable medicinal plants, natives of our own country, which should all be made the subject of experiments.

The effects on the medicinal properties of various manures, of judicious leaf and root pruning where the fruit is required; of encouraging the foliage where the leaves are used,—these are important questions that have scarcely received any attention.

When we read of the enormous sums realized by madder crops, and even by the cultivation of beet in France, it seems that profit as well as knowledge might be the result of such inquiries.

Will no one tell us the cause of that enormous loss we annually sustain, this year worse than ever, by the ravages of the potato disease? No doubt it is a blight, but the existence of that blight shows that the plant is unhealthy, and points to the remedy of obtaining altogether new seed. I am satisfied from my own observation that over-manuring and local seed are strong predisposing causes to the disease. The subject has not been sufficiently studied; the problem is still open to some patient observer, and with its solution, the proud position of proclaiming to a grateful country the means of increasing its food supply.

The analysis of drugs and chemicals must always be an interesting study to the pharmaceutist, if only from the power it gives him of checking adulteration, and ensuring the purity of his materials.

And now a passing word on botany. I look on this science as an absolute necessity to every pharmaceutist; but it is such a delightful and such an easy study, and Providence has so strewn our paths with its beautiful illustrations, that no other inducement ought to be required to capture the inclination of all. No walk can be lonely where you meet so many well-known friends of the animal or vegetable kingdom. I do not wish to undervalue my fellow-men, but there is more pleasure and more instruction to me amongst the floral paths and woods and forests of the country, than in jostling through the crowded streets of a city. Man made the town and God made the country; there is no time for reflection in our busy workshops, and if "one touch of nature makes the whole world kin," seek it where it is to be found in the country.

The microscope is now within the reach of all, and it opens the gates of a new world; with its aid minute beauty and order may be seen in everything. Nothing teaches better the greatness of little things, and the harmony of nature. A speck of mould is a magnificent forest, a drop of water is a sea of life, a grain of dust is full of wonders. No student can read the researches of Deane and Brady without longing for a microscope.

At the risk of being considered tedious, I would in conclusion address a few words to the young men. It is for *you* that the Pharmaceutical Society has been established; *you* will reap the benefits of it. The founders have left *you* the legacy of a good name; they depend upon *you* to make it better; they expect *you* to raise the standard of excellence, of intelligence until the very name of pharmaceutical chemist shall be widely and generally known as synonymous with pharmaceutical perfection. It is a noble aim, and you have plenty to do to reach it. Let me give you a few hints. You will all some day pass your examinations. The first mistake you will make will be that of cramming up the necessary information, I will not oblige you by calling it knowledge; this is a rock that many split on; let me urge you to avoid it. If I were an examiner (which, thank Heaven, I am not), I would pluck without mercy a student who knew the whole Pharmacopœia, if he knew it only by rote; we do not want medical parrots. But if I examined a young patient student who knew a little, but knew it well, and who evinced a desire to learn for learning's sake, I would be very lenient with him. In making this selection, I should act in the interests of the Society, because the first man, like an ill-stuffed turkey, would disgorge his badly digested information immediately after the examination, and never digest any more; he worked for the purpose of passing, and that end being attained, he might as well order his funeral at once, and for any further use his knowledge would be to society at large, they might "see that the body was ready." Whereas the patient student would be a student all his life, and no man can be that, without acquiring knowledge always useful to his fellow-men.

The first mistake is too common, and I cannot too earnestly impress on you that examinations are merely intended as tests of knowledge. You ought to study, not for the examination, but for yourselves; knowledge is power, is money, is happiness, and in the highest of all senses, is everything. Better be plucked if the result be to get more knowledge, than to smuggle through an easy examination; and live and die—a blank.

Another mistake is to suppose that you have not the talent, that you cannot compete with others that have. Abolish the foolish notion; at the risk of being thought a dreadful sceptic, I state here at once that I do not believe in talent; but I *do* believe in industry; and if the two are placed in competition, the latter will always win.

Another mistake that you may fall into is, the idea that you have not opportunities; why, your daily life abounds in opportunities: not a drug you handle, not a poison you dispense but has its history. You ought to know it! Remember the philosopher is the observer of minute differences, he notices just those little things that are beneath the notice of other men, and it is upon these that he builds his theories. Many men saw the apple fall, but Newton alone observed it; and that petty observation has enabled his followers to weigh and measure the solar system. Kettles had been long in use before Watt's time, but in that master-mind a trivial circumstance led to the introduction of a mighty power that does most of the world's work in the present day. Mental blindness is the commonest characteristic of mankind; the habit of daily seeing and never observing the little things that make up our daily life must be shunned. At the risk of offending the Circumlocution Office, be always one of those disagreeable fellows "who wants to know, you know." Make nature tell you the reason why. You will find her wonderfully communicative; and you will find also that, unlike most communicative people, she has plenty of wisdom to impart.

A few words on the economy of time and the dignity of labour. Wellington, Nelson, and all our great men have been rigid economists of time; it is painful to reflect on the fearful waste of time which is so common amongst ordinary men. The older a sensible man grows the more he is compelled to reflect on the rapid advance of time, but it is often only when his powers begin to fail that he looks back on the days he has lost, never to be regained. Employ the fleeting hours, husband your time as you would a limited purse; whatever you do, do it with all your might, for if a thing is worth doing at all, it is always worth doing well; and this brings me to the dignity of labour. Whoever set about that common notion which couples labour with indignity was no friend to the human race. If there be any inheritance which is more than any other the birthright of every healthy man, it is the power of work. It is a proud legacy directly bequeathed to man by the Great Worker who built the universe. I cannot conceive a higher privilege or a greater pleasure than the capacity for doing work of a high order, and doing it well. An active mind in a healthy body is God's best gift. The dignity of labour is nature's nobility, she admits no idlers among her peers. Remember that the highest animals do the most work; and we as the highest have to keep up the labours and knowledge of 6000 years of human experience. Do not be afraid of work, do not be a human vegetable. Over-work may have killed a few, but idleness has dug the graves of millions. Besides the few are remembered for the work they have done, the millions have rolled away unheeded and forgotten. And remember, we are promised that for all labour there is a reward. It is difficult with some to appreciate this in all cases. One of you, for instance, may be called on, at considerable inconvenience to dispense a difficult prescription, perhaps late at night. The paltry couple of shillings you charge is a contemptuous remuneration to you for that labour, But could you see the effect of the potion your hand has mixed; could you stand by the bedside of the poor patient, some loved one of a family, and see the sorrowing relatives; could you note the light coming back to the eyes and the colour to the cheeks, and know that the crisis had passed, and you had been the means of snatching from the jaws of death another victim,—you would then realize the true value of your labour, a value inexpressible in words or money. So we all work, or ought to work, for the common good. "Work, therefore, while it is called to-day, for the night cometh when no man can work."

At the conclusion of the address, the CHAIRMAN proposed a cordial vote of thanks to Mr. Stanford, which was heartily responded to.

Mr. KINNINMONT then moved that a vote of thanks be awarded the Edinburgh representatives for their kindness in being present on the occasion, which was also agreed to,—Messrs. BAILDON and MACKAY briefly acknowledging the compliment.

It was then announced that arrangements had been completed with Dr. R. Carter Moffatt with regard to the special chemistry class, and that it would be commenced on Tuesday evening, November 7th. Fee to non-members of the Association one guinea, and to members 15*s.*, the Association undertaking to make up the balance. Text-book, Attfield's 'Chemistry.'

Mr. BLACK proposed a vote of thanks to Mr. Davison for presiding, which being cordially responded to, the proceedings terminated.

ABERDEEN SCHOOL OF PHARMACY.

The first of a course of lectures, by Dr. Beveridge, in connection with the Society of Chemists and Druggists, for those who have already some knowledge of the business, will be delivered on Monday, 6th of November, at 9.30 A.M., at the Hospital Court, 56, Gallowgate, and continued every Monday, Wednesday, and Saturday morning till 30th March, for the practical study of Materia Medica, with the Chemistry and Botany of the Pharmacopœia.

A summer course of lectures of a more elementary character will be given at the same hour and on the same days, commencing on Monday, 15th April, and terminating on Saturday, 13th July.

Fees for the winter session 25*s.*; fees for the summer session 15*s.*, payable during the first week to the officer, William Adam, at the school.

The employers, who are members of this Society, express an earnest hope that their Assistants and Apprentices will avail themselves of these lectures specially provided for them, and so qualify themselves for passing the necessary examinations of the Pharmaceutical Society.

The Library will be re-opened on Friday, 20th October, when books will be given out from 8 to 10 P.M., and every following Friday at the same hour.

Proceedings of Scientific Societies.

AMERICAN PHARMACEUTICAL ASSOCIATION.

At the opening Meeting of this Association on September 12th, a letter from Mr. W. W. Stoddart, late President of the British Pharmaceutical Conference, was read, introducing the President-Elect, Mr. H. B. Brady. The letter was warmly applauded, and after a few suitable words of introduction by the President,—

Mr. BRADY said: I did not expect, sir, to be called upon so early to express to you the feeling which I was charged to convey from the British Pharmaceutical Conference—the feeling of fraternal sympathy and of greeting to this large and important Association. We hold this Association as in some sort the exemplar which we have endeavoured to follow in establishing the Conference over which I have now, unworthily, the honour to preside. It was said that the organization which we had in London—the central organization in connection with pharmacy in England—was sufficient to provide for the wants of the British pharmaceutists in respect to intercommunication and the like; but it seemed to some of us, some eight or nine years ago, that you had in America an organization which would supplement in a very remarkable degree, if applied to England, the efforts of the Pharmaceutical Society of Great Britain towards the advancement of pharmacy and the amelioration of pharmacists. We followed, therefore, as nearly as we could, and with only such modification as the nature and condition of pharmacy in England, as compared with that in America, necessitated, and endeavoured to form an Association which should, as nearly as possible, resemble that which you have here. How far that Association has been successful may be gathered, not only from the increasing roll of members, but by the amount of, I think I can say without vanity, good work which has proceeded from the association of chemists throughout the country in England, as distinct from the Association in London. It was my happiness that the first meeting, the preliminary meeting of the British Pharmaceutical Conference, should be held in my native town; and from that moment to the present I have missed no step in its career. I do not propose at this moment, when time is so valuable to you at the opening meeting of your Convention, to enlarge either upon our present condition or our past history. I have merely expressed as much as I have to show to you how much I feel we are indebted to you, and with how much brotherly and fraternal sympathy I can meet you, and to thank you for the very hearty and very kind reception which I have met with, not only here in St. Louis, but ever since I landed on the American continent. I take the honour you have done to me this day, in making me one of your members, as a compliment rather to the British Pharmaceutical Conference than to myself; for, to a certain extent, I represent them officially. For them and on their behalf I thank you; for myself it becomes me with simple humility to say from the bottom of my heart, I feel that you have done me great honour.

On Wednesday, September 13th, the Committee appointed to consider the propriety of admitting the credentials of the delegate from the University of Michigan, presented a report recommending that the credentials should be returned.

The Treasurer's report was read, showing a balance on hand of $1209.39. The report was accepted, and referred to an auditing committee.

The committee on nominations presented the appointment of the following gentlemen as officers for the current year, who were duly elected by ballot:—*President:* Enno Sander, St. Louis, Mo. *1st Vice-President:* C. L. Diehl, Louisville, Ky. *2nd Vice-President:* Prof. G. F. H. Markoe, Boston, Mass. *3rd Vice-President:* Mr. F. Ash, Jackson, Mass. *Treasurer:* Chas. A. Tufts, Dover, N.H. *Perm. Secretary:* Prof. J. M. Maisch, Philadelphia, Penn.

A number of gentlemen representing the various sections of the country were appointed on the following committees:—Executive Committee; Committee on Progress of Pharmacy, Drug Markets, Adulterations, Queries, Business, Unofficial Formulæ.

An interesting report on the drug market was read by Mr. M'Kesson, of New York, chairman of the committee for the past year. In it he referred to the new tariff regulations under which many articles formerly paying duty are now admitted free; and traced the influence of the recent war between Germany and France on the drug trade; how speculation was rife, and prices continually fluctuating. Some interesting details were given in reference to the Smyrna opium trade, and the causes which led to the recent extensive alterations in prices, they having varied in New York from $3.75 to $8 or $9. The remarks on quinine showed that the importation of foreign quinine had greatly declined, in consequence of the market being better supplied by the manufacturers in the U.S., their increasing facilities for production having more than kept pace with the increasing demand. Mercury, oil of lemon, and other leading articles were also referred to, and their recent fluctuations in price commented on. The yield of cantharides in Europe was said to have fallen off very much of late, which, if continued, must result in America looking to other quarters for supplies. Last year twenty cases were imported from China, which, although differing in appearance from the European insect, had been found fully efficacious as a vesicating agent. Reference was made to the immense amount of adulteration still carried on, and the hope expressed that a remedy might soon be found for this evil.

Mr. Joseph H. Remmington, of Philadelphia, as chairman of the committee, presented the report on adulterations and sophistications. After some introductory remarks, he proceeded to say that of all substances powders are probably the most liable to adulteration; and that, principally, in consequence of the difficulty of detection. He had been informed of several wholesale drug houses where rooms are set apart for the purpose of mixing powders; and another case where there was a regularly organized adulterating department, with a foreman—of no doubt large experience—to superintend this special branch. All sorts of cheap substances are used in this department of industry, the object being to imitate as nearly as possible the colour and general appearance of the genuine article: flour, starch, terra alba, woody fibre, sawdust, musty ship crackers are all in demand for this purpose.

Spices, on account of their widely-extended use, are of all powders most largely adulterated, and some startling revelations might be made if a spice miller could be persuaded to disgorge his ill-gotten knowledge. The only safe way to get pure powdered drugs is to pay a good price, and buy from conscientious persons who are above suspicion.

Cochineal is adulterated with sulphate of barytes, a heavy white powder, which, when shaken with the insects, lodges in the wrinkles and crevices on the surface of the body. The weight is thus increased sometimes from 15 to 25 per cent.

Balsam of copaiba is often mixed, and sometimes found entirely fictitious, being composed of a mixture of castor oil, resin and oil of copaiba. Powdered ipecacuanha is sometimes so adulterated and weakened that tartar emetic is necessary to strengthen it. Oil of lemon has been met with, mixed with 30 per cent. of fixed oil.

Powdered opium is often mixed with powdered extract of liquorice. In fact, some dealers uniformly send to the grinders a certain proportion of liquorice with the opium, so that they might be ground together. Powdered rhubarb is frequently adulterated with curcuma. Sometimes senega root is mixed with cypripedium.

Castile soap frequently contains an undue proportion of water. It has been met with containing as much as 30 per cent. Acetic acid is also mixed with water, acidulated with dilute sulphuric acid.

Subnitrate of bismuth has been found mixed with phosphate of lime to the extent of 20 per cent., and citrate of iron and quinine adulterated with citrate of ammonia, and containing less quinine than called for, 10 or 15 per cent. instead of 25 per cent. Quinine itself is frequently met with mixed with cinchona, muriate of cinchona and salicine.

Santonine has been found adulterated with small particles of mica, and cream of tartar frequently mixed with tartar emetic. Cream of tartar is grossly adulterated; the terms strictly pure, pure No. 1 and No. 2, being used to indicate varying proportions of cream of tartar and terra alba, the latter material being largely imported from Europe for the express purpose of adulterating, the importations amounting to many tons annually.

Chloroform is sometimes diluted with alcohol, and iodide of potash in crystals mixed with bromide, and occasionally with bicarbonate of potash. Solid extracts are also much adulterated.

In the manufacture of syrup a considerable portion of the sugar is replaced by glucose, especially in making fruit syrups.

This report was warmly applauded, and gave rise to some discussions eliciting additional facts in reference to adulterations. Among others, Prof. Marcoe, of Boston, referred to white castile soap of handsome appearance which he had met with containing 20 per cent. of steatite, which could be detected by its insolubility; and W. Saunders, of London, Ont., to a quantity of oil of peppermint, which has been submitted to him for examination, containing 25 per cent. of castor oil. The presence of this latter, if suspected, may be readily determined by heating a small portion in a test-tube, when the volatile oil is driven off by the heat, the fixed oil remaining in the tube.

The afternoon of Wednesday was devoted to the examination of the magnificent collection of drugs, chemicals and pharmaceutical products brought together in the large upper half of the institute. Foremost among exhibitors of chemicals were Messrs. Powers and Weightman, the well-known manufacturing chemists of Philadelphia. At one corner of their table was an immense block of crystallized alum weighing 700 lb., showing throughout very beautiful and perfect crystals. A huge inverted glass globe contained $600 worth of sulphate of quinine. A second, of similar size, 153 ounces, $700 worth of sulphate of morphia, in blocks of interlaced crystals. An immense bottle of very pure-looking gallic acid; another of sulphate of cinchona, containing 151 oz. There were very fine samples of iodoform, iodide and bromide of potassium, and strychnia in crystals. Also elegant scale preparations, including citrate of iron and quinine, citrate of iron and strychnia, pyrophosphate of iron, soluble citrate of iron, and citrate of iron and manganese. Besides these, there were large bottles containing fine crystals of acetate of zinc, nitrate of ammonia, nitrate of silver and many other salts, which would occupy too much space to enumerate.*

The Association reassembled at 4 o'clock, when Professor PROCTER read the majority report of the Committee appointed to consider the feasibility of holding the International Congress in Philadelphia in 1876. The majority of the Committee report favourably, and urge the project of meeting here, but the minority thought it unwise. Discussion ensued, Messrs. Brady, Maisch, Procter, Parrish and Ebert participating, and on a division, the yeas and nays being called, the vote was largely in favour of the meeting being held in Philadelphia in 1876.

It was afterwards moved and adopted that, if the International Congress do not accept the invitation, a general invitation be extended to the pharmacists of all nations to meet this Association at its annual meeting to be held in Philadelphia in 1876, and that a committee of five be appointed a committee of arrangements, to report at a future (annual) meeting.

Mr. H. B. BRADY then read a paper by Mr. Daniel Hanbury, entitled, "Instructions to the Colony of Virginia of such things as are to be selected and exported to Great Britain." The paper was received with great enthusiasm, and a motion made and adopted that the thanks of the Association be returned to Mr. Hanbury for forwarding it.

The reading of answers to queries and volunteer papers was then commenced. The following are a few of the titles. We hope to be able to furnish some of the more important papers, or abstracts from them, on a future occasion.

The Preparations of Rennet and Pepsin, by Clemens Parrish; the Preparation of Camphor in Powder so that it will remain in that Condition, by Mr. Lowd, of Boston; Extracts of Meat, their Nutritive Value and their Comparison with each other, by Professor Ebert.

On Thursday papers were read on Cantharides, by Dr. E. R. Squibb; the Best Method of making Suppositories Extemporaneously, by Mr. R. B. Ferguson; Chloral, by Dr. Squibb; Adulteration of Olive Oil; Pharmaceutical Education, Citrate of Magnesia, by Professor Markoe and Mr. E. H. Sargent (two papers); the Substitution of Glycerine for Sugar in Fluid Extracts, by Mr. Gordon, etc.

It was decided that next year the Association should meet at Cleveland, Ohio, on the first Tuesday in September.

On Friday papers were read on Wild Cherry Bark, its Collection and the Preparation of the Cold Infusion, by Mr. J. L. Lemberger; the Root of *Pareira Brava*, by Dr. Squibb; Fluid Extract of Senega (two papers); the Preservation of Herbs, by Mr. J. Harrop.

Votes of thanks were passed to the Public School Board for the use of the place of meeting, to the local secretary, and to the "pharmaceutists, druggists and the citizens generally of St. Louis for their cordial and generous hospitality," and shortly afterwards the meeting was adjourned until 1872.

---

* The only collection illustrative of British pharmacy was one forwarded by Messrs. Herring and Co., with an intimation that after the exhibition was closed it was to become the property of the St. Louis College of Pharmacy.

Parliamentary and Law Proceedings.

Cases of Poisoning by Syrup of Poppies.

An inquest was held on Tuesday afternoon, at the 'Golden Lion' Inn, St. Nicholas, Carlisle, before Mr. Carrick, coroner for East Cumberland, on the body of a child eighteen weeks old, the son of John Bell, pattern maker, of Grey Street, and Mary Bell, his wife. The first witness called was—

Mary Bell, mother of the deceased, who stated that the child had been ill from its birth. It had been troubled with wind. Dr. Carlyle had attended it at one time and it recovered. She got it vaccinated, and it became worse. Last Sunday, about six o'clock in the evening, she gave it a teaspoonful of syrup of poppies. The child continued to be restless, but she took it to bed about eleven o'clock, when it seemed to be sleeping as usual. About half-past two o'clock it began to be sick, and they sent for Dr. Carlyle, who came and saw the child, which lived till eight o'clock on Monday morning, when it died. She got the syrup of poppies (two-pennyworth) from Mr. Parker, druggist. It was not labelled poison. She had also given the child a teaspoonful of gin and water and the medicine which Dr. Carlyle had previously prescribed for it.

Dr. Carlyle said he attended the child about three months ago. It was a delicate child. On Monday morning he had been called in at four o'clock. He saw that it had had something, and he made inquiry, but was told it had got nothing but what he had ordered previously. The child was stupefied, and to all appearance comatose. They then told him that they had given it a teaspoonful of poppies at six on the previous evening. He told them the child was dying. Syrup of poppies is very uncertain in its effects. The regular dose for a child of twelve months is from ten to twelve drops. A teaspoon would hold about sixty drops. One teaspoonful would be likely to be a fatal dose for a child like that. Quite sufficient; half the quantity had been known to kill a child.

A Juror: But you don't know the properties? You say it varies.

Witness: It is an uncertain thing, and, therefore, not to be trifled with. Such a dose had been fatal in this case.

Mr. Edward Parker, druggist, said he remembered selling some syrup of poppies to a woman who brought the bottle now produced, on Friday or Saturday evening. (The bottle produced was an ordinary pint castor-oil bottle having affixed to it a blank label bearing Mr. Parker's name and address, and having written in ink on the blank space "Syrup of poppies.") The woman did not tell him for what purpose it was wanted. She did not say anything about it being for a child eighteen weeks old. She asked for two-pennyworth of syrup of poppies and made no remark whatever. He weighed out an ounce into the bottle. Very little had since been taken out of it—perhaps a teaspoonful. The label was already upon the bottle when it was brought to him, having apparently been used for the same purpose before. The writing upon the label was in his own handwriting. A teaspoonful is a dose, and would contain sixty drops.

The Coroner: Do you mean to say you would give a teaspoonful to a child eighteen weeks old?

Witness: I should scarcely give it a teaspoonful if it was eighteen weeks. I should not recommend more than half a teaspoonful for a child eighteen weeks old.

In selling medicines of this kind is it part of your duty to explain to the person buying it what is a proper dose?—Yes, I generally do.

Is it your duty?—Yes. Well, I am not sure it is our duty if we are not asked the question, but if we recommend an article it is our duty.

Assuming this woman came and said she wanted some syrup of poppies without telling you what it was for, is it your duty to explain to her the strength of it and the quantity that could be properly taken?—I can scarcely say that. As the label had been previously on, I should assume from that she was quite aware how to administer it. With regard to the strength of it, I have given a teaspoonful to one of my own children when only a month old, without any bad results, under a doctor's prescription.

Examination continued: It is made of one uniform strength. He made it himself. He did not think the strength varied. Generally a quantity of poppy heads were put together, so that the strength must be uniform.

Dr. Carlyle, on being referred to again, stated that he had the authority of Nelaton, Christison, Pereira and others for saying that for children from ten to twelve months the dose was from ten to twenty drops, and sometimes thirty drops; and they went up to half an ounce, which was four teaspoonfuls, for adults; but the whole of these authorities said it was a very uncertain preparation indeed.

Mr. Parker: Not if it is made according to the Pharmacopœia.

Dr. Carlyle: That depends whether the heads are ripe or not. Green heads contain more opium. The milky juice is extracted from the poppy heads when they are green and not when they are ripe.

The foreman of the jury said he thought it was desirable that the old woman who had gone for the medicine to Mr. Parker's should be called, as Mr. Parker and Dr. Carlyle differed as to the quantity to be given.

The Coroner: With all due deference to Mr. Parker, I think Dr. Carlyle gives and supports his statement with much more authority than Mr. Parker.

Mr. Parker said syrup of poppies was one of those things which he never recommended.

Dr. Carlyle mentioned a case which had recently come under his notice in the country not far from Carlisle, where he had seen a child under the influence of a narcotic showing the appearance which this child presented. He was not attending the child at the time, but attending the mother. The people in the house acknowledged that, as the child was restless and they could not keep it quiet, they gave it something. That showed what people would do. They could not be bothered with the child at night when the mother was ill, so they gave it narcotic.

The Coroner said that there was no doubt that the law required persons dealing in these drugs to exercise certain caution.

The foreman inquired whether such a drug should not be labelled poison.

Mr. Parker replied that after this he should label it so.

Sarah Graham, mother of the mother of the child, with whom she lived, having been sent for, stated that she went to Mr. Parker's and asked for some syrup of poppies one day last week, taking a bottle with her. She asked for Mr. Parker, and asked him if it was a safe thing to give syrup of poppies to a child that was griped, having wind on the stomach, and crying much, and he said it was, in small quantities. She asked him if it required to have a little mixture of water. He said No, it was a syrup of itself and did not require any. She then said to Mr. Parker, "How much might a small quantity be?" He said, "A very small teaspoonful if the child is very bad." Mr. Parker gave witness two-pennyworth and put it in the bottle. She told him that the child was four months old. She could not say whether the label was upon the bottle at the time. She had never taken the bottle before. She was quite certain she had the conversation with Mr. Parker. She turned back from the door after she got the medicine, and that was what passed between them. The child got a small teaspoonful. Before that it had had a teaspoonful of gin and a teaspoonful of warm water.

The Coroner said that the evidence was of a very unsatisfactory and conflicting character, but the last witness cleared herself and her daughter of any blame in the matter. They had taken the precaution of asking what might be given, and no doubt they thought that the quantity given was not likely to produce any ill effects upon the child. That relieved them from blame. Then they came to the question how far Mr. Parker had exercised the caution and care which were due from him. He had no doubt Mr. Parker believed that he might administer the quantity named without doing any harm. Therefore, he did not think they could censure him in the matter, but this case ought to act as a caution to him and to all other druggists. There was no doubt the death of the child had been caused by this poison. The questions for the jury were, in the first place, did they attach any blame to the parents; and, next, did they consider that Mr. Parker had been guilty of any want of care, or that he was exercising the judgment which he believed to be correct and was not, therefore, to be censured. All druggists in selling anything that might produce fatal consequences should be exceedingly guarded, and every one who purchased them should be cautious not to use beyond what was prescribed.

The Foreman: It would be well to have it labelled "poison."

The Coroner said there was an Act of Parliament which rendered that obligatory.

The jury then returned the following verdict:—"That the deceased died from the administration of sixty drops of syrup of poppies given by its mother, Mary Bell, medicinally, in ignorance of its poisonous properties and effects."

The deputy-coroner, D. Wightman, Esq., held an inquest last evening in Sheffield, on the body of a child five weeks old.

Mary Smith, mother of the deceased, stated that the child had been ailing for some time previous to its death; that on Saturday it was seized with a bad cough, and getting worse she sent for a neighbour, named Mrs. Simpson, who advised her to administer a little syrup of poppies. Mrs. Simpson also told her that it was quite harmless, and that she had been in the habit of giving it to her children when suffering from a bad cough. Witness went to the druggist's shop and bought some, and gave the child three-parts of a teaspoonful. She guessed the quantity, but had no idea what a dose of it was. She nursed the child for an hour and a half, when it fell asleep, and was taken to bed. It remained there until four o'clock on Sunday, when witness became alarmed because of it not awaking. On making some inquiries witness was told that she had given the baby rather too much. On looking at the child later on, witness thought it was dying, and immediately went for a doctor, who told her it was dead. Witness further stated that on Sunday morning she gave one of her children, three years of age, a teaspoonful, but that it had done it no harm.

Mr. Smith, surgeon (the medical gentleman who had seen the deceased), said the symptoms were such as would be exhibited by any person who had died from an overdose of an opiate. A teaspoonful of syrup of poppies would be sufficient to poison two or three children of the age of deceased.

A verdict to the effect that "Deceased had died from an overdose of poison, administered with no felonious intention," was returned. The mother of deceased and Mrs. Simpson were then called in the room, and the jury, through the coroner, administered a very severe reprimand to them both for their want of caution, and recommended them to be more careful in future.

Obituary.

SIR RODERICK IMPEY MURCHISON, BART., K.C.B., LL.D., D.C.L., F.R.S., ETC.

This celebrated geologist and geographer died at his residence in Belgrave Square, on Sunday, October 22nd, aged nearly eighty years. He was the eldest son of Mr. Kenneth Murchison, of Tarradale, in Ross-shire, and his wife Barbara, a sister of the late Sir Alexander Mackenzie, Bart., of Fairburn. He was born on the 19th of February, 1792, and received the early part of his education at the Grammar School attached to Durham Cathedral. Afterwards he studied for a few months at the University of Edinburgh. In 1807 he obtained a commission in the army, and, in 1808, served in the 36th Foot with the forces in Spain and Portugal under Lord Wellington, afterwards on the staff of his uncle General Sir Alexander Mackenzie, and finally as captain in the 6th Dragoons. He took part in several of the most important battles, carrying the colours of his regiment at Vimiera, and shared in the dangers of the retreat to Corunna under Sir John Moore.

At the conclusion of the war, following out a suggestion of Sir Humphry Davy, he turned his attention to the study of physical science. His first contribution to the literature of the branch of science with which his name afterwards became so closely associated, was a paper read by him before the Geological Society in 1825, on the "Geological Formation of the North-west Extremity of Sussex and the adjoining parts of Hampshire and Surrey." In 1826 he was elected F.R.S. After some years of investigation, at home and abroad, Mr. Murchison published the conclusions at which he had arrived concerning what he designated the Silurian system; for which he afterwards received the Copley medal of the Royal Society.

In 1846, with M. Verneuil, he commenced a geological survey of the Russian empire, under the countenance of the Imperial Government. Upon presenting his first report, the Emperor Nicholas bestowed on him a decoration and a colossal vase of Siberian aventurine, mounted on a porphyry column, and, three years afterwards, on the completion of the survey, conferred upon him the grand cross of the order of St. Stanislaus.

In 1854, Mr. Murchison published his best-known work, 'Siluria; or, the History of the oldest-known Rocks containing Organic Remains, with a brief sketch of the Distribution of Gold upon the Earth." This leads us to mention that although the discovery of gold in Australia was practically effected by others, the presence of the precious metal in the mountain ranges of that continent, was previously inferred by Sir Roderick Murchison, from their similarity to the Ural Mountains. In his address as President of the Geological Society, in 1844, he predicted the discovery of gold in Australia; and, in 1846, six years before that metal was practically worked there, he addressed a letter to the President of the Royal Geological Society of Cornwall, inciting the unemployed Cornish tin-miners to emigrate and dig for gold in Australia.

Sir Roderick, having acted for five years as Secretary of the Geological Society, became its President in 1831–2, and, again, in 1842–3. He assisted in the formation of the British Association, acting for several years, and presiding over its meeting at Southampton in 1846. In 1844 he was elected President of the Royal Geographical Society,—a post which he held with a few intervals until recently, when he was succeeded by Sir Henry Rawlinson. The persistency with which he has advocated the necessity of sending assistance to Dr. Livingstone, and the faith that he has evinced in the safety of that traveller are too well known to need more than mention here.

In 1855 he succeeded Sir Henry de la Beche as Director of the Museum of Practical Geology. He was also a Trustee of the British Museum and Director-General of the Geological Survey of the United Kingdom.

In 1863 he was nominated K.C.B., and created a baronet in 1866. From the Universities of Oxford, Cambridge and Dublin, and nearly all the learned societies of the Continent, he received recognition of his services to science.

Sir Roderick Murchison married in 1815 a daughter of the late General Hugonin, who died in 1869 without issue; the title becomes extinct. Sir Roderick was seized, two months since, with loss of speech and difficulty of swallowing, which symptoms, however, gradually abated. On the Thursday previous to his death he caught cold while taking a drive, which brought on bronchitis, under which he sank.

CHARLES BABBAGE, F.R.S.

Death has removed a great mathematician and mechanician in the person of Mr. Charles Babbage. Born in 1790, he received his early education from the Rev. Stephen Freeman, of Forty Hill, Enfield, Middlesex, where he had for a schoolfellow the late Captain Marryat, R.N., the novelist. He entered early at Trinity College, Cambridge, and took his B.A. degree in 1814. He did not compete for a Wranglership, as he believed that the late Sir John Herschel was sure to secure the highest place on the list, and Babbage coveted no other; but in 1828 he was nominated to the Lucasian Professorship of Mathematics in his old university, a chair which he held eleven years.

While yet a student at Cambridge he was associated with the late Sir John Herschel and Dean Peacock in advocating the introduction of a knowledge of the more refined analytical methods of Continental mathematicians amongst English students. The result was the formation of the so-called "Analytical Society," and to these efforts may be attributed, in no small degree, the high position now assigned to English mathematics.

Besides some literary work undertaken jointly with the above-mentioned gentlemen, Mr. Babbage published, in 1834, his extremely correct and well arranged 'Tables of Logarithms,' and the difficulty of securing accuracy in the working out of such tables on a large scale seems to have first suggested to him the work by which his name is now best known, the construction of a calculating machine. Having been promised Government assistance, he visited the principal centres of machine labour in this country, and on the Continent, studying the various forms of mechanism and the work performed by each. He then set to work upon his "Difference Engine," and by 1833 had so far advanced in its construction that he was enabled to demonstrate satisfactorily the practicability of his scheme. But as the work went on Babbage's aims were extended; he contemplated also an "Analytical Machine." The Government were alarmed at the possible expense of the experiments; some differences arose with the engineer who had assisted him in the manufacture of the intricate machinery, and the whole project was abandoned, after it had cost its inventor some thousands of pounds from his private purse. The engine and the drawings, after an offer from the Government that they should remain as his property had been declined by Mr. Babbage, were presented, in 1840, to King's College, London.

An able work on 'The Economy of Manufactures and Machinery (1832),' containing the results of the investigations before alluded to, 'A Ninth Bridgewater Treatise,' designed to combat the thesis that the study of mathematics is unfavourable to religious faith; 'The Decline of Science,' and 'Passages on the Life of a Philosopher (1864),' of an autobiographical character, are a few of the other works for which we are indebted to Mr. Babbage. In 1832, he contested unsuccessfully the borough of Finsbury in the advanced liberal interest.

Mr. Babbage died towards the end of last week, at his residence in Dorset Square, in his eightieth year.

Review.

ON THE STUDY AND VALUE OF CHINESE BOTANICAL WORKS; with Notes on the History of Plants and Geographical Botany from Chinese Sources. By E. BRETSCHNEIDER, M.D., Physician of the Russian Legation at Peking. Illustrated with eight Chinese Woodcuts.

Though Dr. Bretschneider professes to be neither a sinologue nor a botanist, he has collected together in this pamphlet of only fifty-one pages some valuable notes on Chinese plants, and their uses. He tells us at the commencement that his object has been to show in what manner the Chinese treat natural science, and specially botany, and what advantage can be drawn by European *savants* from the study of Chinese botanical works.

We have not space to consider this interesting pamphlet in detail, we must therefore content ourselves with a glance at some of its most important and interesting features. The author says, "The Chinese knowledge of plants is as old as their medicine and agriculture, and dates from remote antiquity. In ancient Greece the first botanists were the gatherers of medical plants. In the same manner the ancient Chinese got acquainted with plants for the most part in their application to medical purposes. There is a tradition amongst the Chinese, that the Emperor Shêu-nung, who reigned about 2700 B.C., is the father of agriculture and medicine. He sowed first the five kinds of corn and put together the first treatise on medical plants in a work known as *Shên-nung-pên-ts'ao-king*, classical herbal of Shen-nung (generally quoted by Chinese authors under the name of *pên-king*), which became the foundation of all the later works on the same subject. This is a small work of three chapters, and enumerates, according to the Pên-ts'ao, in all 347 medicines; 239 of them are plants, for the most part wild-growing plants, but only very few cultivated ones. It follows from the accounts given by Li-shi-chêu of the work (preface of the *Pên-ts'ao-kang-mu*), that at first it existed only in verbal tradition. It is not known at what time the *Shên-nung-pên-ts'ao* was first written down, but there can be no doubt that it is one of the most ancient documents of Chinese materia medica.

"Another very ancient work which gives accounts of plants, known by the Chinese in ancient times, is the Rhe-ya, a dictionary of terms used in Chinese ancient writings, which, according to tradition, has been handed down in part from the twelfth century B.C. The greatest part, however, is attributed to Tsu-sia, a disciple of Confucius." In this work, it appears, nearly 300 plants, and as many animals, are enumerated; and drawings are also given. The first purely botanical work in the Chinese language seems to have been by Ki-han, an author of the Tsin dynasty (265–419); after this came numerous works on materia medica and plants, till the appearance of the *Pên-ts'ao-kang-mu*, which is the type of all the Chinese productions of this class. It contains extracts from more than 800 preceding authors, and was published at the close of the sixteenth century, having occupied Li-shi-chêu, its author, thirty years in its preparation.

Though, as we have seen, some attention has been given by the Chinese to the natural history of their country, the properties and applications of the several products have never been properly considered. Dr. Bretschneider remarks that the whole of the Chinese medical science is nonsense; their practice is, for the most part, not the result of experience. They have neither studied anatomy and the physiological functions of the human body, nor have they investigated, free from prejudices and superstition, the effect of their medicines. The art of healing in China is nearly in the same state now as it was forty-six centuries ago. The terms used in Chinese medicine to designate the action of medicines are quite as intelligible to the European as to the Chinese physician. As illustrating this, the following passages, which appear in every Chinese book on medicine, are cited :—

"All medicines that are sweet belong to the element earth and affect the stomach; all medicines that are bitter belong to the element fire, which enters the heart," etc.

"All medicines, on account of their properties that are cold, hot, warm, and cool, belong to the *yang*, or male energy in nature; while their tastes, as sour, bitter, sweet, acid, and salt, belong to the *yin*, or female energy."

Another passage, which we quote, illustrates the singular minds of these remarkable people :—

"The upper and lower, the internal and external, parts of medicinal plants have each their corresponding effects on the human system. The peel or bark has influence over the flesh and skin; the heart (pith) operates on the viscera, etc. The upper half of the roots of medicinal plants has the properties of ascending the system, while the lower half has that of descending."

Besides the use by Chinese physicians of products having no active properties whatever, it is remarkable how indifferent they are as to the quality of the articles they use. The means of preserving drugs in a Chinese shop are such, that many of them soon lose their efficacy, if they ever had any. In the neighbourhood of Peking there is to be found an abundance of excellent peppermint, containing much more volatile oil than our European plants; but the exsiccated plants, obtained from the Chinese druggists, differ scarcely from hay. It is likewise difficult to find in the Chinese apothecaries' shops rhubarb of good quality. Although the best rhubarb in European commerce is that brought from China, that used commonly in China is worm-eaten and of little value.

The *Soja hispida*, commonly known as the Soy bean, appears to be a food plant of some importance in China. Three varieties are known, a black, a white, and a yellow sort. This plant is much cultivated in tropical Asia for the purpose of making the well-known sauce called Soy, which is valued perhaps as much by Europeans as Asiatics for flavouring dishes. The Chinese, moreover, make a kind of bean curd in large quantities from the seeds. The beans are macerated in water, and then pounded together into a pulp, the liquid matter is filtered and some gypsum added, in order to coagulate it; when thus prepared, it is of a jelly-like consistence, and is much prized. In Manchuria large quantities of these beans are produced, and are employed chiefly for the expression of oil which is used both for cooking and for burning in lamps. The residue of the beans after pressure is formed into cakes, which are exported to Swatow for manuring the sugar plantations.

Amongst Chinese fruits, the most popular is the jujube (*Zizyphus*, spp.). Several sorts are known; the largest and best being called Chinese dates. The dry spring branches of some of these shrubs, and *not* those of *Caragana spinosa*, as has been described in many European works, are used, our author tells us, for protecting the tops of the walls of prisons and other official buildings.

These are a few illustrations of facts about Chinese plants which we do not remember having seen in European works.

The author gives a glance at what has been done by Europeans in the matter of Chinese drugs, and pays a well-merited tribute to Mr. D. Hanbury's 'Notes on Chinese Materia Medica,' published in this Journal.

The pamphlet is illustrated with eight plates,—Chinese drawings of plants,—and was printed at Foochow.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Council of the North British Branch of the Pharmaceutical Society.

Sir,—The letter of "M. P. S." in your publication of Saturday is so inaccurate, and so full of irrelevant matter, that it scarcely deserves either notice or reply.

I would, however, suggest, in order that the correspondence which has now continued for so long regarding the origin and position of the Council of the North British Branch of the Pharmaceutical Society be brought to a close, or that at all events an undoubted and incontrovertible authority may be given for its existence,—the following course be adopted by all those interested in the matter, but especially the gentleman who still mysteriously shrouds his name and locality under the three capitals "M. P. S."

The Journal is undoubtedly the official organ of the Society, but instead of going *back a few volumes*, I would respectfully ask your readers to get Volume XII., and, turning to page 530, read an account of the second anniversary of our branch in Edinburgh, held on *4th April*, 1853, and, with the same book of reference before them, further ask a perusal of the Annual Report of the London Council (folio 573), held in Bloomsbury Square on the *18th May*, 1853. Our constitution and recognition are so fully set forth in these pages, and emanating, as the remarks on the twelfth anniversary of the Society do, from the Council in London, I apprehend nothing more convincing will be required to set at rest the feeling of jealousy which has been recently manifested by a few of our members for reasons which appear to me to be as uncalled for as they are unfounded.

John Mackay.

Edinburgh, Oct. 23rd, 1871.

[*** We have no desire to enter into the merits of this question, which appears to be more suited for consideration by the Council of the Society; but in reference to the letters which have appeared we must, in fairness, state that our correspondent "*M. P. S.*" was in error as to the time when the title "North British Branch" was first adopted, as will be seen by reference to the reports mentioned by Mr. Mackay. The correspondence on this subject must now be closed, so far as this Journal is concerned.—Ed. Pharm. Journ.]

Improved Tincture Press.

Sir,—Will you kindly insert these few lines on a subject which appears just now to be attracting considerable attention, viz. the screw tincture press?

In order to make my meaning clearer, I will begin by explaining in detail the principles on which the mechanical advantage of the screw-press rests.

This implement is a compound of two simple machines,—the wheel and axle and the screw; the first being a modification of the lever, and the second of the inclined plane.

Usually only two spokes are substituted for the entire wheel, although Messrs. Hayward Tyler and Co.'s new press is an example to the contrary.

The mechanical advantage (A) of this part of the press is the ratio borne by the radius of the wheel to the radius of the axle, or more correctly, by the length of the spoke or arm to the radius of the screw.

Let these be represented by R, r;

$$\text{then } A = \frac{R}{r}$$

and, multiplying each term of the fraction by 2 and by 3·1416, we get—

$$A = \frac{C}{c}$$

where C, c represent the circumferences of the wheel and of the screw respectively, since twice the radius of any circle, multiplied by 3·1416, gives the circumference.

Also the mechanical advantage (B) of the screw is the ratio of its circumference to the pitch or the distance between the threads (P), that is—

$$B = \frac{c}{p}$$

The mechanical advantage of the compound machine is the product of those of its parts, or

$$A . B = \frac{C}{c} \cdot \frac{c}{p} = \frac{C}{p}$$

= the ratio of the circumference of the circle described by the arm to the pitch of the screw, as stated by Mr. Umney.

I may illustrate this by giving the dimensions of my own press,—a half gallon one, by Maw, Son and Thompson,—as also for the sake of comparing them with those of presses by other makers:—

Pitch of screw . . . . . . $\frac{3}{16}$ in.
Total length of levers . . $14\frac{3}{8}$ in.

In estimating the power of the press, the arm should be measured from the centre of the screw to the point where the force is applied; which, it is clear, cannot be the extremity of the lever, but must be the point through which the resultant of the forces exerted by the fingers passes.

Practically I believe this coincides with the point of greatest thickness in the arm, and I find that, in the case given, this is distant from the centre of the screw $5\frac{1}{2}$ inches, therefore, the pressure obtained by applying a force of 50 lb. to the arm

$$= \frac{50 . 5·5 . 2 . 3·1416}{\frac{3}{16}} = 9215 \text{ lb. or rather more than 4 tons.}$$

This is abundantly sufficient, unless carefully managed, to burst the cylinder; and so far as my experience goes, presses are most frequently disabled from this cause, and not, as Mr. Staples suggests, from the bending or breaking of the screw.

The suggestion made by the same gentleman that strong block-tin would answer for the cylinder of a press made on his principle, seemed to me inconsistent with the pressure which he calculates is to be obtained, viz. 30 tons; and, on examining his account of the model, I find that he claims an additional advantage obtained by reducing the bulk of the screw; this is a mistake, as an inspection of the expression given above will show;

$$\text{if } AB = \frac{Cc}{cp}$$

it is evident that no increase or diminution of c, the circumference of the screw, will affect the value of AB.

Whether he is right or wrong in assuming that the power is doubled by the employment of two screws, I will not pretend to decide; but it is self-evident that one assistant cannot work both screws at once, and, also, that unless the force is applied alternately to each screw in rapid succession, it will act obliquely instead of perpendicularly.

In conclusion, I hope that among your correspondents some will be found undeterred by Mr. Staples's epithet of "unprofitable," from entering upon a "discussion of the theoretical power of the screw-press," with a view of clearing up this and other doubtful points.

J. Fred. Brown.

Sir,—Would Mr. Staples kindly inform me whether he has at any time driven his press to the enormous force of, say, twenty tons, not to speak of his latest computation? To my way of thinking, after taking into consideration the shape of his cross-beam, it seems but strange that his working model should have existed for so many years without meeting with anything more fatal than one case of undue violence. I would venture to suggest, therefore, to those who purpose getting presses made after his design, to have them made with more depth in the centre of the cross-beam, and also sufficient room in the same for the play of the male screws.

Warrington, October 24th, 1871. C. E. D.

Sir,—When I wrote the description of my press, it was to give freely to the world the benefit of an implement on which I had bestowed much thought, care and labour before I even produced the rude model from which my sketch was taken, and which I have found from experience to be very simple, convenient, of very great power, and last, though not least, so inexpensive as to be within the reach of every chemist; for I believe, with a fair division of labour, it could be produced at a cost much below that of the cumbersome and inefficient implement in general use. And there, I had thought, my duty ceased; I neither expected nor desired to be drawn into this controversy; but I am prepared to maintain my opinion while I think I am in the right. Now, the issue between Mr. Umney and myself is limited to the power applied to the lever, and I am in hopes of convincing him that my estimate is nearly correct. As Mr. Umney again quotes Professor Rankine, I must again remind him that such an excellent authority would not have given the same estimate of power, for intermittent labour, with ample time to recruit the strength, as he gives where it is continuous and exhaustive. I have just now taken the opinion of a gentleman who has looked at and handled my press, and thinks my estimate of 100 lb. within the mark, as he could apply 200 lb. (not continuously, but at intervals); being a mathematical scholar, well up in the sciences, I think his opinion of some value. But as I said last week, do not talk about a thing if it can be done; an ounce of practice is worth a pound of theory. I challenge Mr. Umney to the following test, in which, perhaps some other of your readers will aid us. Let the press, when in actual use and a fair amount of power applied, be turned on its side with the lever projecting horizontally, load the end and note the weight required to move it; if Mr. Umney's theory of 50 lb. applied by the two hands to both arms of the lever is correct, one arm should move with little more than than 25 lb.; I say, "try if you can do it."

October 24th, 1871. C. A. Staples.

The Preliminary Examination.

Sir,—There was a mournful sentence in the last Pharmaceutical Journal. "First, or Preliminary Examination. Two hundred and twenty-two candidates presented themselves for this Examination on the 2nd of October, eighty-two failed."

Something is wrong. Either apprentices and young students do not care a straw for the subjects on which they are engaged save just so far as their study may enable them to pass an examination, or else they are miserably trained.

As every little helps may I be allowed to say a word.

Before I was an acting Examiner I amused myself by preparing private friends for the Preliminary. It was then vivâ voce. I did this—First I went to the nearest Day School, connected either with Church or Chapel, and engaged a *junior* master to attend two nights a week for one hour each time, to teach Arithmetic. Secondly, I asked a curate to instruct in English Literature and Composition. The advantage of having an educated gentleman to explain the English language cannot be over-estimated. The time was divided thus—half an hour was devoted to a rigid grind of Grammar and Composition: while during the second half hour the pupil had to read aloud some book of standard excellence—such as the Vicar of Wakefield, The Essays of Elia, Southey's Book of the Church, Ivanhoe, or the Talisman—these works being as far removed from Pharmaceutical subjects as the East is from the West—also large portions of the Bible, specially the Psalms and Isaiah—and celebrated known passages such as Addison's Papers in the Spectator.

Thirdly—I gave two morning lessons of one hour each in Latin. The time was accurately divided (the watch being on the table) into two distinct studies—Half an hour was consecrated to a thorough grind in Latin Grammar and composition: half an hour was allotted to the reading of the first book of Cæsar.

Three months' preparation was exacted. At the end of the eleventh week, an examination paper was drawn up containing eight questions on each subject—Latin, Arithmetic, and English.

Then, I forbade my student, for the next week to touch a book. I put it to his honour, for *my* sake, not to tinker up his Latin, addle himself over Arithmetic, or exhaust himself with English. I certify that I never had one failure, nor was it necessary to look to near the gulf stream to find out where the name of the candidate was inserted on the list. On a calm revision of the matter I do not see where a possibility of failure could occur.

I have written nothing original, nor indeed do my remarks seem to myself worth print—my only excuse is the dismal paragraph above quoted. I *am* my brother's keeper, and it is my duty to see after the eighty and two lost sheep straying in the wilderness. To them I say—let the dead bury their dead—let the past go: Enter once more with full hope the intellectual life and recollect the splendid motto "Ride through." Joseph Ince.

Sir,—In the Latin paper set for the candidates at the recent Preliminary Examination occurs this question, "How is the noun-adjective of three articles declined?" One of the candidates, who had been reading with me before the examination and was quite unable to understand the question, was courteously furnished, by Mr. Haselden, with this explanation, quoted from Edwards's Eton Latin Grammar (1858), "Noun-adjectives of three articles are declined like nouns of the third declension,—*e.g.* HIC and HÆC *tristis;* HOC *triste.*" Now if this be what is meant by an adjective being "of three articles," I should like to ask what declension HIC *bonus,* HÆC *bona,* HOC *bonum* resembles. I might further quote Donaldson, Smith, Arnold, and Priscian to the effect that in Latin there are no articles, and equally high authorities as to the inappropriateness of the term "noun-adjective;" but I would hasten to draw your attention to the fact, that with respect to examinations the Pharmaceutical Society is undoubtedly behind the age. Of course in the Arithmetic papers the Examiners could not go far wrong, but in the Latin and English questions there is great room for improvement. In the former subject, for example, following the text-books of the last generation—the questions are either ridiculously easy or such as will be found unanswered throughout the voluminous works of Arnold, Smith, Kennedy, etc. And in the English papers, the Definite and Indefinite Articles are pertinaciously adhered to, while the modern improvements in the nomenclature of pronouns are regarded as dangerous innovations. I do hope, Sir, that some attention will be given to this subject, so that in the future there may be more confidence in the examination-system, and less injustice towards the candidates.

You must not think I have written these lines from any ill-will towards the examiners, for I am happy to say the only gentleman who read with me succeeded in passing, though he did not answer the question quoted.

W. E. SNELL, Lond. Univ.

PROVINCIAL EDUCATION.

Sir,—I should like to say a few words in reply to Mr. Mason's letter in last week's Journal.

I do not know whether Mr. Mason is a practical man with regard to pharmaceutical education, but from his letter I should rather think that such is not the case. He does not seem to agree with Mr. Smith's plan of making the Minor the main object of provincial associations, but rather seems to think that the great desire of apprentices is to "cram."

Now I maintain that such is not the case. From what I know of provincial associations, I have found that the large majority consists of the apprentices, and the Preliminary being passed, what have they next to do but to study for the Minor, and such being the case, what becomes the principal object of associations but the Minor? And as for cramming, I know from my own experience of apprentices that nine-tenths of them abhor cramming, and honestly desire to thoroughly master the required subjects. To say that apprentices must cram, is to say that those who enter our ranks are beneath ordinary traders in mental abilities; and yet Mr. Mason, I have no doubt, would declare that the rising pharmacist is in every respect a superior man. So long as the Minor remains compulsory and the Major permissive, the candidates for the Minor will greatly exceed those of the Major; but to make the difference less, let every attention be paid to apprentices and their studies by provincial associations, and the result will greatly exceed their expectations.

October 24th, 1871. SPECTATOR.

TRADE LATINITY.

Sir,—The budding genius of Dr. Kitto was annoyed at the business announcements of his neighbourhood, "Logins for singel men," "Rooms to leet, enquair withing," and he prepared neat and accurate substitutes, which he sold at a very modest rate. If some person would perform a similar office for our trade Latinity, it might save us from many a glaring absurdity, and remove a stumbling-block from the way of those unfortunate apprentices whose "Preliminary" succeeds their indentures. A "happy family" is congruity compared with the confused numbers, genders and cases of trade lists and advertisements. In a short price-list of pharmaceutical preparations only, I have counted no less than two dozen errors in that portion which remains in type from month to month. How many others the friendly contractions hid I cannot conjecture. In an advertisement a short time since, often repeated, a youth fresh from school, with the Concords firmly impressed on his mind, would have had no difficulty in rendering the Latin* for creeping solution of wheat, though he might wonder whether the preparation was intended for the microscopic exhibition of animalcules analogous to "eels in paste;" but he would be utterly unable to construe "liquor quinæ ammoniata."

It is, however, the misfortune of many persons to be obliged to use a language very foreign to them. But the insertion of a Latin motto on the title page of the price list of a chemists' association must be optional, and it would not be hypercritical to demand correctness. In such a sentence† I find gratuitous accents are so placed that an adjective is made to appear an adverb, and in two instances neuters plural of the second declension and accusative case are converted into ablatives singular of the first declension, governed by the preposition *per!* If these errors are all to be laid upon that scapegoat, the printer's devil, surely some means of exorcism should be found. Professional men, and the educated part of the public, whose eyes may perchance fall upon such examples of Latinity, will be apt lightly to estimate our claim to be considered an educated body.

HENRICUS.

J. Abbott.—Our correspondent appears to confound *Nardostachys Jatamansi* (the Spikenard of the ancients) with Sumbul. To the latter alone apply the remarks of doubt as to its botanical origin. By some it has been supposed to be the root of a Valerianaceous plant, probably of *N. Jatamansi,* but by others, and more recently, it has been attributed to an Umbelliferous plant. See PHARM. JOURN. 3rd Ser. Vol. I. p. 807.

H. Sparshott.—Your letter and enclosure has been forwarded to the publisher.

"*Give and Take.*"—See Mr. Allchin's paper on "The Preservation of Leeches," PHARM. JOURN. 1st Ser. Vol. XV. p. 453.

A. P. S.—We would recommend you to communicate with Mr. F. Baden Benger, the Hon. Secretary of the Manchester Chemists and Druggists' Association.

Dispensing Charges.—*Mr. W. M. Betts,* in reply to Mr. Leay's comments on a former communication of his (*ante,* pp. 260, 300), says that it is an absurdity to call each item in a prescription a pennyworth, and that anything like a business establishment would ridicule the very thought. He asks whether the "pet of the period, the Intelligent British Artisan," would fill a bottle with pure water for nothing? and expresses an opinion that if pharmacists stand behind the counter and serve the public for nothing, the public will estimate their worth at its proper value.

"*Inquirer.*"—There is such an examination. For information respecting it you should apply at Apothecaries' Hall.

J. T. Chapman.—Your letter has been handed to the Secretary.

C. Glaister.—The advertisement has been forwarded to the publishers.

T. Cragg.—Candidates for the Preliminary Examination in London and the provinces must present themselves on one of the regularly appointed days, viz. the first Mondays in January, April, July and October.

P. E. Fox.—A recipe for making green fire will be found in Vol. I. p. 357 of this series.

A. Williams.—6 x 6 [*pollices*=] inches.

"*Scribo.*"—For information as to the preparation of Pancreatine, you may consult the paper by Dr. Dobell on "The Special Action of the Pancreas on Fat and Starch," read before the Royal Society, and published in the 'Proceedings of the Royal Society,' vol. xvi. p. 209.

T. Hambridge.—The derivations are not positively known.

T. Small.—Candidates who pass their examination in Edinburgh may compete for the prizes given in London at the end of the Session.

* Liquor Tritici Repens" (*sic*).

COMMUNICATIONS, LETTERS, etc., have been received from Mr. T. Cragg, Mr. G. C. Jones, Mr. Prowse, Mr. J. A. Wilson, Mr. J. Tully, Mr. J. T. Miller, Mr. B. Keene, Mr. J. J. Matthias, Mr. E. Nuttall, Mr. W. Watts, Mr. J. H. D. Jenkinson, A. B., C. E. D., "Chemist's Assistant," "A Chemist," "Nil Admirari," "Spectator."

A NEW EXCIPIENT FOR PILLS.*

BY J. B. BARNES.

Soluble cream of tartar is a solution of bitartrate of potash in biborate of soda, boracic acid, or biborate of soda and tartaric acid; either of these compounds, when evaporated to the consistence of mucilage, is heavy and adhesive.

Having had my attention directed in an especial manner to the medicinal properties of sulphur, I was naturally led to reflect upon the inelegant mode of its administration. It is true the sulphur electuary of the Pharmacopœia is an improvement upon the horrible mixture of sulphur and treacle in common use, but still there is the grittiness and the mess. Sulphur is generally taken in combination with bitartrate of potash; and the soluble modification of this salt possessing the above-mentioned properties, it suggested to my mind the employment of so appropriate an excipient for the conversion of this substance into pills; and I venture to suggest that pills so prepared might be employed when this substance is required to be taken in doses of between four and twenty grains.

The samples of sulphur pills on the table, prepared respectively with the sublimed and precipitated varieties, contain in each four or five grains, together with one grain in twelve pills of gum tragacanth and a sufficient quantity of soluble cream of tartar. The pills containing four grains of precipitated sulphur are smaller than it is possible to prepare them with any of the ordinary excipients, being not quite so large as a five-grain compound rhubarb pill, and as hard as a lozenge. When placed in tepid water, the soluble cream of tartar speedily dissolves and the sulphur is set free.

I propose to call them "sulphur and cream of tartar pills."

I have also prepared five-grain pills of hydrate of chloral, Dover's powder, nitrate of potash, chlorate of potash, citrate of potash and gallic acid. The formula used for the chloral pills is as follows:—

Hydrate of Chloral	1 drm.
Soluble Cream of Tartar (of the consistence of mucilage)	2 drops.
Gum Tragacanth	3 grs.

Mix and divide into twelve pills. These require to be kept in contact with lycopodium. They keep their form perfectly and gradually harden; minute glistening particles of the drug have, however, made their appearance on the surface of these pills, and also on the bottle, indicating that they should not be made too long before they are required to be used.

In the conversion of Dover's powder into pills, soluble cream of tartar only was used; for those of nitrate of potash and chlorate of potash one grain to the drachm of gum tragacanth was employed, in addition to the soluble cream of tartar; for those of citrate of potash and gallic acid took two grains of the gum to each dozen. The nitrate of potash, chlorate of potash, gallic acid and citrate of potash pills were dried at a gentle heat; the three former keep well in boxes; those of citrate of potash should be kept in bottles in contact with lycopodium. With the exception of the gallic acid, all these pills are smaller than an ordinary five-grain pill.

I have also prepared four-grain pills of chloride of ammonium, using the soluble cream of tartar, and one-sixth of a grain gum tragacanth in each; these should also be kept in well-closed bottles.

The one-grain camphor and three-grain quinine pills on the table contain, in addition to the soluble cream of tartar, one-twelfth of a grain gum tragacanth in each. The gallic acid pill, as might have been expected, is large but hard, keeps well, and makes a more satisfactory pill than when glycerin is used; all these pills are firm, dissolve quickly in tepid water, and, what is of considerable importance, present a good appearance.

I thought it probable that by boiling trisnitrate of bismuth in a solution of soluble cream of tartar a soluble bismuth pill might be prepared, but I find it takes seven grains of the dried salt to dissolve one grain of the trisnitrate. I have, however, prepared four grain pills of this body, which contain half a grain of the trisnitrate in each.

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britan, Nov. 1, 1871.

CINCHONA-TREES GROWN IN INDIA.*

BY JOHN ELIOT HOWARD, F.L.S., ETC.

I received in the course of the past summer, by favour of the Indian Government, two trees, complete with roots, trunk, branches and leaves, not living, but packed in cases. I had requested to be furnished with these for the purposes of chemical analysis, in order to clear up some points which yet remained (in some measure) undecided. I reserve till another occasion what I may have to say on the leaves, and proceed to some observations on the trees themselves, which both grew in the Government gardens, Ootacamund, and were cut down near the close of last year, after a growth of about five years.

The first was a tree of *Cinchona succirubra*. The height from the base to the summit of what may be called the stem, was 10 feet, and above this, there may have been from 6 inches to a foot of young and merely succulent vegetation. The girth of the base of the trunk was 20 inches, of the summit, where cut from the succulent part, 2 inches. The weight of the roots was 8 pounds; of the trunk, 12 pounds 8 ounces; of the branches, 4 pounds 8 ounces; of small branches, 3 pounds 12 ounces, making together a total of 28 pounds 12 ounces. This tree was four and a quarter years old, according to Mr. Broughton's reckoning, probably from the time it was planted out. The second was a tree of *Cinchona officinalis*, the height of which I estimate at 9 feet 3 inches, with less immature vegetation above. The girth at the base was 11 inches; at the summit (as above), 1 inch. The weight of the roots was 3 pounds 8 ounces; that of the trunk was 5 pounds 12 ounces; that of the branches, 13 ounces, making altogether 10 pounds 1 ounce.

These figures show that the *C. succirubra* will develope in the time at least three times faster than the *C. officinalis*, a circumstance accounted for by the great abundance of its leafy branches, whilst the general aspect of the Loja-tree, a stem bearing a tuft of vegetation on the summit, has caused it to be compared to the Aloe. Thus we have, in this case, a weight in the *officinalis* of only 13 oz.

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, Nov. 1, 1871.

branches to set against a total of 132 oz. of branches in the former, or more than ten times the amount. The weight of the trunk itself proves to be in each case about 50 per cent. above that of the roots. I am not able to state the comparative weight of the bark of the two trees, which could not be removed without spoiling the specimens, except a portion of the *C. succirubra* for chemical examination. It is thicker in the *C. officinalis*. This tree is said to be five years old.

It is important to remark that this rapid development of the *succirubra* by no means necessarily implies a corresponding success in the cultivation of this species. If the quinine found in the bark of the *C. officinalis* prove to be three times the amount in the same time, and of purer quality than in the *C. succirubra*, and supposing the relative weight of the bark to be the same, the preferential price would be given for the one-third weight of *C. officinalis*. The average of a parcel of *C. succirubra* recently cut, and now coming home, is, I am informed, *under* 1 per cent., but the average of the *C. officinalis* coming in the same parcel is *over* 3 per cent. of sulphate of quinine.

At the first sight I was struck with the general resemblance of the external aspect of the two trees to the same sorts grown in their native climate. This was especially the case with the *C. officinalis*, which seems in all respects to be the exact reproduction of the plant named by Pavon *Cinchona Uritusinga*, but which has now been restored by Dr. Hooker to the old Linnean designation. It will be seen on examination of the marked and peculiar rugose bark of the two specimens placed side by side—one gathered by Pavon one hundred years since in South America, the other recently cut in India—that even in colour and the adherent lichens they are as much the same as if they had been taken from the same tree. This is the more remarkable, because the other forms of the Loja bark are remarkably and characteristically different. I lay some stress on this, because it appears to me that such permanent characteristics as the bark affords should always be taken into account in the botanical discrimination of these otherwise nearly allied forms.

A second general observation presented itself on closer inspection, namely, the occurrence on the lower part of the trunk of each tree of a peculiar white fungus occupying the crevices of the bark; and, as I afterwards found, penetrating into the very wood itself, and occupying cracks and fissures in the same. I look upon this as a very bad indication; and, judging from the analogy of beech-trees similarly affected in plantations here, should regard it as an almost fatal sign. I hope that it does not generally occur in the Indian plantations, but that its accidental existence in these trees may, in part, have led to their selection for the purpose of eradication. I present to the Society a portion of bark of the under part of the stem of a Calisaya tree grown in Java, and "infected by mycelium." This arose, as is well known, from the decaying portions of old roots and trunks of the uprooted forest, in place of which the cinchona-trees were expected to flourish. I do not know whether the same or a different cause may have led to the existence of this fungus on the trees at Ootacamund. Mr. M'Ivor explained this evil to me as arising from the earth being heaped up for some inches around the base of the trunk, in which case it may have had a simply local origin. It is well known that all the cinchonæ are impatient of water at the roots, and if the water lodges in the least in the subsoil (Mr. Clarke remarks at Darjeeling), although it may be a place where there is an excellent fall and surface drainage, there is a bald patch in the plantation.* I should certainly look to the roots.

I now turn to the results of chemical examination. My attention had been arrested by a passage,† in which, after speaking of the permanence of the alkaloids in the bark after it has been removed from the tree, Mr. Broughton remarks, "in very singular contrast to this is the fact, that quinine and cinchonidine are not to be found in the bark of trees *that have been dead a short time.*

My own experiments with barks that have been a century in this country leads me to suppose that no change whatever had taken place in the alkaloids, and I was naturally anxious to ascertain what could lead to such a result as we have been contemplating. Has the plant, I said to myself, withdrawn these alkaloids in order that they might be turned to other account in the failing health of the plant? Mr. Broughton also, in a private letter to myself, speaking of the trees sent, says, "I am a little doubtful whether the quality of the bark will not be damaged by allowing it to dry on the tree, since I find that if a tree dies from any cause, its bark loses its alkaloids in a few weeks."

I therefore, on receipt of the trees, separated enough of the bark of the *C. succirubra* to ascertain this point, and soon satisfied myself that no such injurious action had taken place in this case; probably because the sudden death of the tree prevented any abnormal circulation. The bark yielded me 3·54 per cent. of alkaloids, of which only 0·82 proved to be quinine, the rest cinchonidine and cinchonine,—the former pure and good, as will be seen by the sample shown; the latter, on the contrary, losing much weight in refining. The bark, in fact, resembled that taken from similar trees in the ordinary method.

The bark of the roots I have not had the opportunity of examining. It is so thin, and adheres with so much pertinacity to the wood, that it would seem lost labour to attempt its separation in any quantity in the dried state, whatever may be the case when the roots are freshly removed from the earth.

The examination of the heart-wood yielded me results analogous to that from South America, with this exception, that I found less cincho-tannic acid than in the wood from South America, and also a small portion of chlorophyll, which I have before noted in the young wood from India, as the result, perhaps, of a vigorous circulation not yet fully settled into the mature state of the tree. This may also account for a less specific gravity. I found (by ether) the same resinous-looking yellow substance which I have described in my 'East Indian Quinology.' This is capable of being split into chinova-bitter and cincho-tannic acid, and consequently, by treatment with alkalies, productive of cinchona-red, the proportion of which seems to be less in the red bark of India. The chinova-bitter obtained is pure and abundant.

I hope that the examination of the leaves may

* Report, 1st July, 1870.

† Return, No. 432, 9th August, 1870, p. 241.

afford me some topics of interest, but these must be reserved for another opportunity.

I embrace the present opportunity of introducing to the notice of the Society some carefully prepared botanical specimens of the valuable variety of *Cinchona officinalis*, known as the *lanceolate* variety. It was first pointed out by Mr. Broughton, the able chemist in charge at Ootacamund, in a report dated 17th August, 1868, and was subsequently (in 1869) shown to contain "the unprecedently large proportion of 11·40 per cent. of alkaloids and 9·75 of quinine." * My own examination of a small sample forwarded by Mr. Broughton confirmed, as to its main features, this extraordinary report; and as orders were issued and resolutions taken to increase this most valuable species, it seems to me that we should soon hear more about the success of its cultivation.

The same remark applies to the Pitayo species, first raised about the same time from seed, sent by Mr. Robert Cross. I hope that this valuable sort is not neglected.

In August, 1868, mention is also made by Mr. Broughton of the variety *Amarilla del rey* of the *C. officinalis*. If this proves still to exist, it would be well worth while to send over a selected and carefully prepared specimen of the bark. I studied this kind in conjunction with Dr. Pereira, and know that it is rich in quinine and altogether a most valuable article of the materia medica. Moreover, it used to fetch (as HO crown) a deservedly very high price in the market. Now it is impossible to procure either this or any other crown or Loja barks of the genuine sort in this country, and I have had difficulty in obtaining even a few ounces for a collection of specimens.

It is by devoting attention to such points, by encouraging the best species and by high cultivation, that the undertaking of Indian acclimatization will become one of pecuniary profit. I am glad to think that all things seem to promise an abundant return to the careful cultivator, and that the pecuniary result is beginning to be realized from shipments sent home to Europe. There can be no doubt that on the whole this great experiment is a success.

PHARMACY IN NORTH GERMANY AND AUSTRIA.†

BY THOMAS GREENISH, F.C.S.

In the early part of September I left England for a month's holiday in North Germany and Austria. Two days found me among the pharmacies of Hamburg. It was no easy matter to discover them. Every other shop had the usual outward aspect peculiar to the same trade in England; but, had it not been for the one word "Apotheke" over the door, there would have been nothing in the external appearance to denote the existence of a pharmacy within. The shop windows were little, if anything, larger than those of a private house; and there was nothing displayed in them either to attract the attention of the public or to bring "grist to the mill."

It is rarely that you enter directly from the street into the shop; the outer door is open, but the true shop door generally remains closed. There is usually one counter for retail, and another behind it for dispensing. Once inside, it is evident at a glance that the business is mainly one of prescriptions; there is an entire absence of patent medicines and proprietary preparations; counter bills recommending specifics are not seen; and all the *etcetera* that go to make up the retail of an English pharmacist find no place there. Even the ubiquitous feeding-bottle is not allowed standing-room, and one wonders how the "budding Germans" get on without them, when such a variety and so many are required in England.

The whole shop has the appearance of being one dispensing department; the pots on the shelves have their labels burnt in, those on the bottles are done in oil colour and varnished; while the dispensing-counter, with its marble top and neat dispensing scales,—for every ingredient in a prescription, excepting drops, is weighed, graduated glasses being unknown,—convey to the mind an appearance of "well to do," which subsequent observation tends to confirm. This quiet dignity and professional air contrast strongly with the very pronounced character of many of our English pharmacies. Fly labels are used exclusively, and the bottle rolled up in a piece of paper, which is twisted at the neck, is, with the prescription loose, given into the hands of the patient. To a British pharmacist this mode of sending out medicines would appear somewhat "slip-shod." Prescription wrappers are seldom seen, and the neatness considered so essential in England is unknown here. In one instance I observed a servant leave a pharmacy with a bottle of medicine in her hand; it was rolled in paper, but the label was outside, and as, just at that time, heavy rain was falling, it would be difficult to say how much of the direction was delivered with the medicine.

The prescriptions, which are written in Latin, with the directions in German, are, as a rule, more simple than those to which we are accustomed; the meagre slips of paper which contain them seem scarcely sufficient for anything very complex. The competition which prevails in England is unknown here. The practice of pharmacy is a Government concession, and the number of establishments cannot be increased without the Government permission, which is never granted unless proof be adduced that there exists a necessity for it in the increase of population. Application is then made to the minister of the medical department, and the prayer must be supported by the "Kreis Physicus," or Government medical officer for the district. This limitation of pharmacies, coupled with the fact that no class of the medical profession sends out its own medicine, throws a great number of prescriptions into the hands of the pharmacist. As a counterpoise to this privilege, he is supplied with an "Arznei-taxe," or taxed list of prices for medicine, which he may charge, but which he is not allowed to exceed. There is also an "Arznei-Mitteln," compiled by Messrs. Schacht and Laux, of Berlin; it contains the prices of those preparations which, although in general use, are not in the Pharmacopœia. It is without legal authority, yet it is accepted by the trade, and is in general use throughout North Germany.

In addition to the price of each article in the prescription, charged in accordance with the "Arznei-taxe," the pharmacist can also add a small item each for weighing, dissolving and mixing the ingre-

* Return, No. 432, p. 221.

† Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, Nov. 1, 1871.

dients, and also for the distilled water; the sum total, with the bottle, being usually about two-thirds the price of the same mixture dispensed in England. In some towns a trifle extra is permitted for a more elegant label and capping-paper.

The "Arznei-taxe" would be the alpha and omega of many in England, who think uniformity of prices the great desideratum, and occupy the valuable pages of our Journal in discussing and recommending this utopian scheme. Others there are who believe that if all the dispensing were done by the pharmacist, no class of the medical profession sending out its own medicine, the "winter of their discontent would be glorious summer." Here both exist in full perfection, and that sharp competition, based too frequently on low prices alone, which in England suddenly starts up, and may at any time deprive the conscientious pharmacist of the fruit of years of labour, is not permitted in Germany. Civil Service Associations, if they do exist, may supply to their members any mortal thing from a "silk dress" to a "Bath brick," from "Cockle's Pills" to the "latest fashion in chignons;" but the dispensing of physicians' prescriptions is the province of the pharmacist alone, and the divinity "which doth hedge a king" is not more sacred than the protection afforded by Government to the legitimate dispenser of medicines.

"Obscure prescriptions" are unknown, and the equally questionable practice of prescribing preparations for which the formula has never been published finds no place in German pharmacy. The pharmacist having all the dispensing does not cultivate prescribing, he discountenances it; and the small charge made by the physician enables him to do so without inflicting an injury on his customer. An examination of the drugs, chemicals and pharmaceutical preparations is supposed to take place about every three years. It is conducted by the Government medical officer and a chemist; but, although no notice is given, somehow or other it leaks out when the examination may be expected; and hence, for all practical purposes, it is not of much value. I was invited to inspect several very complete laboratories in Hamburg, Brunswick and Berlin. Until within the last ten years every pharmacist was bound to make the preparations of the pharmacopœia in his own laboratory; since that time he has been at liberty to purchase. But the examiners still hold them responsible for the quality of every article found on the premises. In Hamburg the number of pharmacies is 46 or 48 to 200,000 inhabitants; and this number is considered to be too great, the average all through North Germany being one to about 10,000 inhabitants.

Such is an outline of pharmacy in Hamburg, and with little variation it applies to the whole of North Germany.

From Hamburg I passed on to Hanover, which, with its suburbs, has a population of about 80,000. There are 7 pharmacies. The difficulty of getting apprentices was a subject of complaint; and in matters of detail as regards pharmacy there was little or no difference between this place and Hamburg.

Brunswick came next in my route, with its population of 52,000 and 4 pharmacies; and it was remarked to me that there was great difficulty in getting assistants; and the reason assigned was that the salaries were low throughout Germany, averaging £20 per annum, and for examined men £25 to £35 a year. The position did not afford a comfortable living, and there was little prospect of getting into business. I was here informed that if by an error in dispensing, an assistant who had passed his final examination at the university caused the death of a patient, the principal was not criminally responsible, nor liable to damages in a civil action; but this was not subsequently confirmed, and I therefore think that it must have been an error, unless it applies to Brunswick alone.

I then went on to Berlin. Here, with a population of about 800,000 there are 53 pharmacies; however, this city is rapidly increasing, and before long it will, no doubt, have an addition to this number. The North German Pharmaceutical Society meets here every month, at which meetings neither apprentices nor assistants are allowed to be present. The Berlin chemists are not all connected with it. The meetings are generally held in a hotel, where a room has been rented for this purpose, and trade affairs, as well as scientific matters, are discussed. There is no regular library, but several journals are taken, among them the Pharmaceutical Journal, the *American Journal of Pharmacy*, and the *Journal de Pharmacie*; these are sent round to each member for a term of three days. The society has no special organ to publish its proceedings; the *Pharmaceutische Zeitung* is a private undertaking, and has no connection with the Berlin Society. The members pay annually a certain sum to an Assistants' Benevolent Fund for every assistant they keep. The assistants have founded an association for social and scientific purposes; but there is no systematic lecturing, or special botanical or chemical class. Assistants have no time allowed them for attending lectures. Apprentices are allowed to attend a course on botany and chemistry.

In Leipzig there are 91,500 inhabitants and 8 pharmacies, besides 2 which deal exclusively in homœopathic medicines. There exists here a chemists' association, which meets once a month and discusses trade and scientific affairs; from this society also assistants and apprentices are excluded.

To Dresden I paid my next visit, and found a great deviation from the usual character of pharmacies in North Germany, perhaps in deference to the habits of the very large number of English families always resident here. Nearly all the pharmacies had proprietary articles and patent medicines exposed in the windows; there was more of the *shop* about them; and to my mind it was a falling off in character. To a population of 150,000 there are 20 pharmacies.

With regard to pharmacopœias, there has hitherto been in North Germany a great variety. Hamburg until lately had its own, so also had Hanover; Dresden used the German Pharmacopœia for Saxony; but now they seem in a transition state, and are gradually approximating to the Prussian Pharmacopœia. Each also had an "Arznei-taxe" of its own, but in a year or two they expect to have one uniform German Pharmacopœia, and also one "Arznei-taxe" issued from Berlin. Prussia has absorbed these minor states; but at present they are like those particles seen by microscopists wriggling in the stomach of the Hydra, swallowed but not assimilated.

It is unusual for assistants whilst in a situation to attend any lectures; all this is left until they go to the university, when their whole time is devoted to study and practical work. There seemed to be no society in any part of North Germany in furtherance of the objects of pharmacy to which assistants had free access.

The hours of business are very long. Assistants are required, in summer, to be in the shop at half-past six, and in winter at seven, and to continue there until ten at night, with very little relief on Sundays; but they are allowed, usually, two afternoons a week for recreation. I noticed that, as a rule, the assistants were older than those in England. In many instances they had passed their final examination, and were fully qualified, but wanted an opening. A pharmacy in Germany realizes, on sale, a very large sum, more than the returns would warrant, or than it would be worth without the Government concession. It becomes a valuable property, less liable to depreciation than a similar establishment in England, and when there is one in the market, it is the subject of a very sharp competition.

The working details of the business of pharmacy under different conditions to those which obtain in this country, must always possess a certain amount of interest, and may generally be studied with advantage, but there are other and closely-allied subjects of more importance which demand our notice also; I allude to those laws by which the practice of pharmacy is regulated, and also to the education of the pharmacist. There are points here to which I invite your special attention. In North Germany every *candidate* for apprenticeship, before he is accepted by the pharmacist, must produce his certificate to show that he has been one year in the second class of the Gymnasium, and that he possesses those educational qualifications which entitle him to the privilege of having to serve for one year only in the army instead of for three years. The Gymnasium is the classical school of Germany,—it has six classes, the second being the highest but one. This qualification would comprise a knowledge of grammar and composition, Latin, French, history, the simple rules of arithmetic, vulgar and decimal fractions, the elements of physics and chemistry and some botany. It would be about equivalent to the Oxford and Cambridge Middle Class Examinations and those of the College of Preceptors, and until an education equal to this be insisted on by those who in this country take apprentices, it will be idle to talk of raising pharmacy in Great Britain to what should be its true position in public confidence and professional estimation. "A chain is only as strong as its weakest link," and this is the weak link in our educational arrangements. The Preliminary Examinations reveal a lamentable amount of deficient education, and result in much unhappiness and disappointment.

No amount of after cramming can compensate for the absence of that mental discipline which is the result of careful early education. This is a subject for the consideration of individual members, and the duties of the schoolmaster should not be thrown on the Pharmaceutical Society.

If pharmacy is to be elevated, our youth must have acquired *at school* such an education as will leave the *entire term* of their apprenticeship perfectly free for the acquisition of scientific knowledge and the technical details of the business, instead of wasting a large portion of it in acquiring the very rudiments of the Latin language, which properly belongs to the duties and obligations of school, and then to fail in the simplest English composition. This, or such as this, is required to place us in scientific attainments abreast of our brethren on the Continent, and the pharmacist who, *before* apprenticeship, insists on the youth possessing such an education as is implied here, will have done a splendid service to pharmacy, and have earned for himself the lasting gratitude of his brethren. We must ever remember that it is in the education of our youth that the safety of the public lies.

In Germany the apprentice is allowed his evenings for study, and his employer is bound to provide him with suitable books and to superintend his studies; he is also allowed time to attend lectures, if in a town where lectures are delivered, and for the first two years or thereabouts he is confined to the dispensing of *external* medicines. At the termination of his three years' apprenticeship, he has to pass an examination something equivalent to our *Minor*, before a board composed of the Government medical officer, a chemist and a pharmacist; if he fails, he is sent back for six months; if he succeeds, he commences his term of three years as an assistant; this also is compulsory, and, at its expiration, he goes to the university, usually Leipzig or Berlin, for three *semesters*, or sessions, equal to about one year and a half, where his work is practical and theoretical; after this, he has to undergo his final examination, which is equivalent to our Major. I have calculated the cost of these three *semesters* at the university for a German student, and think that with economy it may be done, including board and lodging, and the fees, for £80 English money. If successful, he is then qualified to conduct a pharmacy when he can get one, but must wait until a vacancy occurs.

How often is it remarked, and with truth, by business men, that assistants who present themselves with the most satisfactory testimonials and the highest scientific attainments—attainments which reflect the greatest credit on this school—are utterly wanting in the practical experience necessary for the details of business! So long as pharmacy is like Jacob's ladder, one end on earth although the other may be very high up, so long will the vulgar details of existence imperatively claim our attention. This state of things is provided against in Germany by the three years' practical work as an assistant, before the university duties are commenced and the Major examination can be passed.

There is yet another subject on which there has been some difference of opinion, viz. the age at which a young man should present himself for his Major examination. There is no stated age in Germany, but the curriculum of study provides for it. The student must *before* apprenticeship have acquired the necessary classical, mathematical, historical and scientific knowledge; and it is scarcely possible that he can have acquired it before the age of fifteen, it is usually sixteen, to which add three years' apprenticeship, and also three years as an assistant; and, this with one and a half at the university, will make him about twenty-two years of age before he can offer himself for the final examination.* I think

* It is expected that some important modifications will soon be introduced into the system of pharmaceutical education in Germany, and we purpose next week giving some details of the contemplated changes, which have been communicated by Dr. Schacht, of Berlin, who is a member of the Commission that has to deal with pharmaceutical affairs in Prussia.—ED. PHARM. JOURN.

the German student, on leaving the university, is more highly educated than the average of those who pass the Major in England, and I attribute this mainly to the early education he receives, an education on which it is easy to raise any required scientific superstructure.

I now approach some of those laws by which pharmacy is governed in North Germany. The question will very naturally occur to the English pharmacist, Is this Government concession and limitation of pharmacies an advantage to the public, or conducive to the best interests of pharmacy? The question is very difficult to answer, but some facts may be mentioned which have a direct bearing on the subject. In every place I visited, from Hamburg to Dresden, it was remarked how difficult it had become to obtain apprentices, although no premium was ever expected from them. The reason assigned was, that the high-class education required, and the severe examinations which follow, deter them from entering the business, while the prospect of possessing a business themselves is remote and uncertain. It follows that assistants also are scarce. As an instance, I had in my hands one number of the *Pharmaceutische Zeitung*, in which there were ten advertisements for apprentices, six for situations, and 124 for assistants. For these the prospect of business is remote and uncertain; they may have passed their Major examination, and shown themselves fitted for conducting a pharmacy, yet assistants they must remain until a vacancy occurs by death or retirement, and even then the purchase-money required is so large that comparatively few can ever hope to possess it.

Having qualified, what inducement is there for continuous study? None, but an inherent love of the science. Once established in business, competition is not feared; and that most natural incentive to progress is entirely wanting. Again as regards the "Arznei-taxe," if the taxed list of prices be quite proper for the wealthy, it must press very hard upon the mechanic. In England it is usual to study the means of the working classes, but in Germany medicines are regulated by one code of prices.

There seems to me a general lack of interest in pharmacy in towns like Hanover and Brunswick, and also in Dresden; there is a want of union among the principals, and there are no societies where apprentices and assistants have opportunities of study. In Great Britain there is a cry from different parts of the country, reaching the parent Society in Bloomsbury Square, asking for assistance in money, books, diagrams and apparatus. It may be difficult to satisfy those wants, but they indicate vitality and a healthy feeling. I have heard nothing of the kind in North Germany.

The data which I have here brought before you have been obtained with much care and labour, usually from two or more independent sources in every town or city; I believe them to be facts and not coloured. For the inferences I am alone responsible. I know, at the same time, that on this subject opinions in Germany are much divided; those who are now in business believe in the present condition of things, those who are not, and "their name is legion," think otherwise.

I take this opportunity of stating the pleasure it afforded me to hear how highly the Pharmaceutical Society of Great Britain is appreciated by the pharmacists of North Germany; but I cannot avoid the conclusion that pharmacy there is now suffering from over-legislation, that the limitation of establishments and Government protection is not conducive to its best interests, and that it has at the present time, looming before it, the most serious questions—questions which press for solution, and must one day be grappled with and solved; and I believe that it is not at the present time in a satisfactory and progressive condition.

Leaving Dresden, and with it Northern Germany on my way to Austria, I shouldered my knapsack, and crossing the Elbe, spent a few days in Saxon Switzerland, where, amidst the moss-grown and lichened rocks of that romantic spot, I forgot, for the time, that there existed such a science as pharmacy.*

DIGITALIS.†

BY J. MILNER FOTHERGILL, M.D.

(*Concluded from page 324.*)

Action on Frogs.—These have purposely been put last, on account of the large number of experiments to which they have been subjected by various writers. Frogs have been made much use of by experimenters, on account of their great susceptibility to medicines, and the ease with which experiments could be carried on. Dybkowsky and Pellikan abroad, and Hilton Fagge and Stevenson in England, experimented largely on them, with uniform results as regards the state of contraction of the heart observed. Dr. Fothergill found that when digitalis was administered by the mouth, or hypodermically, its effects were quickly apparent. First, the contractions became somewhat quicker, and the contraction more complete. Soon the peristaltic action became more marked, the systole being longer and more perfect. Then the distension became less complete, especially at the apex, which remained white and firmly contracted. The action of the ventricle became almost vermicular in its slowness, and the diastole was most imperfect, till the ventricle came ultimately to a standstill in firm contraction, the heart being much diminished in size,—and in size, shape and colour, much resembled an unripe apple-pip. The frogs did not seem much affected otherwise, the poison seeming to be confined, as regarded its action, purely to the heart. If released, they hopped about unconcernedly, nor did the removal of the contracted heart by scissors cause them any apparent inconvenience. They merely seemed to die ultimately from the arrested respiratory changes: a slow mode of death in cold-blooded animals. The results were uniform as regards the contracted condition of the ventricle. To other frogs were administered belladonna, caffein, strychnin and aconite. The first produced rather marked contraction; caffein somewhat less so. Strychnin produced no perceptible effect, contrary to anticipation. Aconite produced paralysis and arrest of the heart in diastole. A still more interesting series of experiments was performed. To some frogs, digitalis and aconite were administered, side by side, and the opposite actions contrasted. The experiment was then varied; and, after the action of each drug was well established, the other was administered—*i. e.*, after the effects of digitalis were well established, aconite was administered; and to others, after the action of aconite was well brought out, digitalis was given. Over the action of digitalis, aconite certainly had an influence, but it could scarcely be called a marked one, and did not ultimately arrest the contraction produced, even when pushed. On the contrary, the administration of digitalis was followed by the most marked

---

* The author purposes dealing with the subject of Pharmacy in Austria in a future paper.

† Abstracted from the Hastings Prize Essay, for 1870, published in the *British Medical Journal*, Nos. 548 to 553.

results, when aconite had been given, and the ventricle had become gradually more and more distended, and its contractions more and more imperfect,—each contraction merely expelling a small quantity of blood off the top of the distended ventricle, the contractions becoming slower and slower, and less and less perfect, until a condition of advanced dilatation had been artificially produced; and even when the heart seemed to have given up all action, and remained in diastole, distended with blood and inert. When all action had apparently ceased, the first effect was to produce an imperfect contraction at long intervals; then the intervals became shorter and the contractions more complete, some irregularity both as to time and amount of contraction being observed. Slowly and gradually, however, the distended ventricle recovered itself under the action of digitalis, the contractions being more rhythmical and perfect, and the distension less and less pronounced, until a return to normal contraction and distension was brought about. If the administration of digitalis were then continued, the same appearances were brought out as when no aconite had been previously given. This interesting experiment was frequently performed before other medical observers, and can be readily repeated. In all the experiments the ventricle was the most affected; in the frog, where there is only one ventricle, the auricle could only remain distended behind it, incapable of getting rid of its contents into the firmly contracted ventricle in front, and of course it could not contract unless its contents could be disposed of: if the venous sinuses behind were pricked, as in the case of the minnows, the auricles soon became contracted. As regards the effects upon the rhythm, the general results may be stated broadly thus: at first there were occasional slow beats, interposed without any exact order; and then, as the effect became more marked, the slow beats preponderated, until the contractions were only occasional before complete cessation in systole. During an experiment on a dog by Brunton and Gamgee, a temporary murmur was observed, which they concluded was due, and apparently with good reason, to an irregular action of the musculi papillares, producing imperfect closure of the mitral valve.

In these experiments on the frog, sometimes the tincture of digitalis was used, and at other times the infusion. In some instances, a solution of digitalin was used, but its effect in producing increased contraction was certainly not so marked as when a preparation was used which contained the other principles. It is not intended that this statement should convey the impression that there exists any good reason for supposing that digitalin is not the active principle in digitalis; but such is the writer's experience.

Hilton Fagge and Stevenson found that, sometimes, the ventricle makes only one pulsation for two of the auricle, the number of its contractions being therefore lessened one-half (Transactions of the Royal Society, May 1865, Conclusion 3). Reid seems to think that sometimes more than one auricular systole is necessary to produce such ventricular distension as would excite contraction. This seems in accordance with reason and fact.

Antidotes.—In cases of poisoning where it is known that the symptoms arise from the use of digitalis, and not from attacks of cardiac syncope, the use of agents must be resorted to which are known to paralyse the heart,—for instance, aconite. Although in the experiment on the frog, the action of aconite on the heart after the poisonous effects of digitalis had been induced was far from being so marked as when digitalis was given in aconite-poisoning, aconite might prove of service as an antidote to digitalis. From the action of the Calabar bean, as described by Dr. T. R. Fraser, of Edinburgh, it is highly probable that it would act beneficially in the excessive action of digitalis. This leads the author to consider the question of agents of similar action.

Drugs of similar Power.—The whole question of agents acting upon the heart so as to increase its power of contraction is comparatively new. With the exception of digitalis we are, generally speaking, scarcely acquainted with their names. The agents are either entirely new, or nothing has hitherto been known of their secondary effect upon the heart. The list of them is a short one, and will not take up much space in the enumeration. Thus Dr. Clifford Allbutt has advocated the use of Virginian cherry-juice (*Prunus Virginiana*) in cardiac affections; Dr. John Harley has investigated the action of belladonna; Dr. Braidwood the action of dajasck, or arrow-poison of Borneo (*Tanghanina venenifera*); Drs. Hilton Fagge and Stevenson have investigated the action of the *Scilla maritima* and the *Helleborus viridis;* and Leven has investigated caffein and thein. Of these, the writer has only experimented on digitalis, belladonna, and caffein. There is thus plenty of opportunity for investigating further the action of these drugs, and adding to what we already know of their action; while there is a ground for hope that to this list may be added new agents more certain, more effective, and more manageable than those we as yet possess. Dr. Fothergill considers that by thus treating digitalis as a member of a class of agents, it will much facilitate the investigation into the usefulness, or uselessness, of a drug as a cardiac neurotic. It is obvious that other agents which increase the ventricular contraction and bring the heart to a standstill in systole, must necessarily possess a therapeutic value allied to that of digitalis. In prosecuting such an inquiry, it will be easy to ascertain to what extent the action is common to that of the whole class, or in what it is singular. This grouping of agents as to action will assist us in aggregating a number of agents with either a primary or secondary effect upon the heart; in time this will constitute a group, and in practice the remote effect of an agent upon the heart will be taken into consideration in the choice of therapeutic agents. It is only by the grouping of agents and then testing them by clinical experience and physiological experiment, observing the successes, the failures, and their causes, that we can expect to emerge from our present therapeutical chaos. Thus, under our old plan of empirical testing of agents, colchicum has six or eight times been removed in and out again of our Pharmacopœia. The same, to a less extent, has occurred to numerous other agents of no trifling activity. It is obvious that the use of these agents has been conducted on nothing approaching a law, else some definite conclusions one way or the other must have been arrived at. Without some definite idea of what it is we want exactly to attain, and by what action our agent is likely to achieve the desired result, we cannot be said to do anything more than—to use a vulgarism—"make shots." The experiments of Crum Brown and Frazer into the physiological and chemical agency of drugs, and Broadbent's valuable speculations on chemical tension, and the question of the retardation or aiding of oxidation as a mode of explaining the action of many agents, are steps in the right direction, the value of which we are scarcely yet in a position to correctly estimate.

The Use of Digitalis.—Like other vegetable substances, digitalis is prepared for use by either tincture, infusion, extract, or separation of the active principle digitalin. The extract is little used. The tincture is the most convenient form ordinarily, but throws down a dark green precipitate with iron, which detracts from its desirability. For general use, it can be given along with the ammonio-citrate of iron, or, still better, the potassio-tartrate. It is better kept in a dark cupboard or wrapped in a dark coloured paper, as light is supposed to act deleteriously upon it, weakening it and lowering its activity. The infusion is a good preparation for use along with potash or diuretics, and is conveniently added to vegetable infusions. Digitalin in solution may be the most elegant form, and perhaps may be found ultimately to be the most exact form for accurate administration; but in some experiments on frogs, a solution of digitalin did not produce such a decided effect as the tincture upon the ventricular contractions. It is possible that the other constituents, digitalose, digitalic acid, etc. may possess properties peculiar to themselves; and when the importance of a knowledge of the action of different agents on the heart-walls becomes fully recognized—for as yet we are only on the threshold of the inquiry—a careful investigation of them may not be barren in results. In the treatment of chronic conditions, when it is necessary to keep up the administration of digitalis until structural changes are produced, Dr. Fothergill considers that perhaps the powdered leaves are the most desirable form. In this form, digitalis can be given in pills with the dried sulphate of iron, carminatives, laxatives, or both, and in this form will keep some time, and can be given twice a day without causing the patients to revolt at its nauseous taste, or creating any aversion, on æsthetic principles, to its muddy-looking combination with iron. For long, a favourite form of pill with him for persistent use has been a combination of half a grain to a grain of powdered digitalis, with an equal quantity of the dried sulphate of iron in powder, and a morsel of cayenne, in extract of gentian, or aloes and myrrh pill, thus securing an action on the circulation, the addition of iron in a form which will act locally on the stomach, and thus act as an astringent in the gastric catarrh so common among sufferers from heart-disease; while the carminative action of the cayenne is useful, and also takes off the griping from the action of the laxative, when an action is also necessary, as is commonly the case, on the bowels.

In cases where there is a risk of digitalis disordering the stomach, it may be administered by absorption through the skin by means of poultices of the leaves or flannels soaked in the infusion, or a mixture of the tincture and water applied to the abdomen and thighs. Hypodermic injection is another mode of administering it, and Bouillaud pursued an endermic treatment by dusting a blister over the heart with from six to fifteen grains of powdered digitalis.

NICKEL PLATING AS APPLIED TO PHOTOGRAPHIC PURPOSES.

BY JOHN SPILLER, F.C.S.

About ten years ago, when visiting the bank-note printing establishment of Messrs. Bradbury and Wilkinson, of Fetter Lane, I was shown some nickel-coated plates from which the "nature printing" specimens had been prepared, and had an opportunity of seeing the electro-deposition of pure nickel upon copper and other metals practically carried out as one of the branches of their printing operations. This process was being applied conjointly with, or as a substitute for, the method of steel facing (*aciérage*) of which they are the patentees, and it struck me at once that the permanent quality of the nickel deposit so formed was capable of wider application, and might serve as a means of protecting steel objects from the rusting influence of damp air.

At my suggestion a few steel articles—particularly a dinner-knife, spatula, and split-ring—were coated with nickel, in order to test the degree of protection which such a process would offer when applied to swords, bayonets, helmets, breast-plates, spurs, harness chains, and steel accoutrements generally. The experiment proved perfectly successful, and without prejudice to the colour, and steps were then taken with the view of submitting the idea to the notice of the War Office authorities, particularly as the cost of applying such a process did not appear likely to stand in the way of its general adoption when the great saving of time in cleaning these articles was duly taken into account.

Beyond establishing the fact, no immediate result followed, and from that time to the present year the application of electro-deposited nickel has, so far as I am aware, been restricted to the specific purposes for which Messrs. Bradbury and Wilkinson have continued to apply it in their establishment. Within the last two or three years fresh attempts in my original direction have led to the employment of this process in America, where a patent was taken out for the application, and a company now working under a licence of the American patentees has recently commenced operations in London and Birmingham. I am indebted to the energetic manager of the Plating Company (Limited), Mr. Channer, of 34, Kirby Street, Hatton Garden, for the opportunity of inspecting a vast collection of objects to which the nickel-coating has been applied, and have been furnished likewise with small specimens of copper, brass, and steel coated with the metal in question, by which I am enabled to substantiate the statements made in their prospectus relative to the wonderful degree of protection afforded to the underlying metals by the superficial deposit of pure nickel. I have since had my regulation sword coated at their works, and find it now perfectly secured against rusting in wet weather, and so easily kept in condition that the blade and scabbard require only to be wiped with a washleather, instead of undergoing the tedious process of burnishing, to fit it for appearance on parade.

A small square bar of steel similarly coated has been repeatedly immersed in water for hours together without showing any signs of rusting, and I find it possible to bury it in flowers of sulphur for several days without tarnishing the lustre of the nickel surface. Neither has this latter severe test any effect upon the copper and brass bars upon which the nickel coating has been applied, and these metals may even be immersed in an aqueous solution of nitrate of silver without effecting the reduction of that metal. In one of the angles only, where the coating seems to be imperfect, was there any indication of silver reduction in the case of the brass tube, the steel bar being perfectly protected over the whole surface against the action of silver and copper solutions. Here, then, is a valuable property which I was not led to anticipate in the case of electro-deposited nickel, for I could not have predicted from my chemical knowledge that a metal of the zinc and iron group would be proof against the action of nitrate of silver; but the experiment proves it to be so, and we must regard pure nickel as belonging (from this point of view) to the class of noble metals, resisting, like gold and platinum, the attack of sulphur and of highly corrosive metallic solutions.

The nickel facing, when burnished, has a whiter colour than polished steel, although not equal to silver itself, its aspect being rather that of rolled platinum. A chemist to whom I showed the specimens pronounced them at once to be very similar to platinum in regard to colour, thus confirming my own impression on this head. It withstands the action of heat also remarkably well, for the fusion-point is very high, and oxidation occurs only at elevated temperatures. With the view of testing its general applicability to laboratory work, I am having a brass scale-pan coated with nickel, and will report later as to its success. For fine balance beams and weights, lens mountings, reflectors, laboratory microscopes, Sykes's hydrometers, still-worms, egg-beaters, camera fittings and a variety of apparatus used by the chemist and photographer, the nickel coating will probably find extensive application; and I have seen some oval picture-frames of very pretty effect made from stamped brass coated with nickel. It remains to be mentioned that burnished and matt surfaces of this metal may be used in combination for ornamental purposes.—*Photographic News.*

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 4, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

AMERICAN COURTESIES TO ENGLISH PHARMACISTS.

As will be seen from the report on another page, the proceedings of the Evening Meeting on Wednesday last were considerably increased in interest by the presence of Mr. H. B. BRADY, who had just returned from a visit to America, where he had been present, in a semi-official character, as President-Elect of the British Pharmaceutical Conference, at the meeting of the American Pharmaceutical Association at St. Louis. Invited by the CHAIRMAN to furnish some particulars of his journey, Mr. BRADY complied by giving a short account, which cannot but be a source of gratification amongst all those who have the welfare of pharmacy at heart, although it is to be hoped that it will be supplemented by the half-promised fuller narrative when, to use his own words, "the events of the last two or three months have come to something like a reasonable focus in his brain." The influence of such kindness as that displayed by our American brethren towards Mr. BRADY, being, as it was, only a repetition of the goodwill experienced by Mr. HOWDEN, must be productive of great good in a national as well as in an individual sense; and pharmaceutists, surprised out of themselves to find that it only requires an ocean rolling between their places of business to enable them to discern so many good points in their brethren, will be better prepared to give and to receive acts of kindness from those with whom they have to enter into close competition in business.

Though Mr. BRADY's reception in the States was, to a great extent, the natural result of a high-class scientific reputation which superseded all need for introduction, we are sure that the hospitality displayed towards him by pharmaceutists will be esteemed by their English brethren as a compliment paid to the whole body in the person of a representative man, and should an opportunity occur, the kindness would, doubtless, be heartily reciprocated by them.

At the recent meeting at St. Louis it was determined that invitations should be issued to the pharmacists of all nations to meet the Association at Philadelphia in 1876, and we hope on that occasion England will be well represented, though it is in the power of few to leave their business for so long a time as such a visit would require. But to those who must needs be content with a few days' relaxation we would venture to say that an equal amount of gratification and profit is to be obtained at the meetings of their own countrymen in connection with the Society of which Mr. BRADY is so worthy a President.

On the occasion of a former meeting of the American Pharmaceutical Association we remember the question "Who is SAUNDERS?" having been asked with an evident feeling of cockney bewilderment, in reference to the statement that this gentleman had taken a very active part in the proceedings, and we are glad to find that Mr. BRADY's account of his pharmaceutical colleagues at St. Louis affords material for dispelling a mystery that we were informed neither the Pharmaceutical Register nor the Directory could solve.

THE CONSUMPTION OF CHLORAL HYDRATE.

WHAT becomes of all the chloral? a question recently asked by our contemporary the *Lancet*, and founded upon a statement made in a private letter, received by Dr. GEORGE HARLEY from Baron LIEBIG, has elicited several attempts to answer it. Baron LIEBIG had been told, by a chemical manufacturer, that he made half a ton of chloral hydrate weekly, and that the drug is used in such enormous quantities in Germany and England as to prohibit the belief that its employment is limited to the sphere of medicine alone, some persons affirming that it finds its way into beer.

The problem of the philosopher and the manufacturer in Germany has met with easy solution by certain journalists in England, and doubtless they think the matter is closed up. But there is a difficulty in congratulating them, inasmuch as they do not agree. The *Spectator*, advancing a few steps in the road wherein another weekly journal has found a certain kind of notoriety, pooh-poohs the beer theory. It says that taking chloral is the new and popular vice, particularly among women, and informs us that the drug is kept in thousands of dressing-cases, while those who begin its use often grow so addicted to it that they pass their lives in a sort of contented satisfaction.

Here the *Echo* steps in with the pertinent remark that what with alcohol, sherry, lavender drops, laudanum, pick-me-ups and now chloral, a lady's dressing-case must be something between a medicine chest and a dust-bin; while "A Druggist's Shopboy"—who, by the bye, with a shopboy's propensity to exaggeration when talking of his employers, increases the number of manufacturers producing half a ton weekly to twelve—furnishes a curious calculation that sixty grain-doses would be thus provided daily for 204,000 habitual chloral drunkards. But the *Echo* is equally dogmatic, and after a learned disquisition, in which we are informed that there is every reason to believe that chloral, like digitalis, is a "cumulative" drug, and that a course of small doses has as fatal an effect as one big dose, it decides that beer drinkers are the great consumers of chloral hydrate. It is explained that the property possessed by cocculus indicus, of inducing great thirst and making the victim lazy, and disposing him to linger where he may at the time be seated, is shared by chloral hydrate, whilst the latter has the extra recommendation of costing less. Should this explanation be true, there will be matter for the serious consideration of all beer drinkers—especially in view of the cumulative properties—and we may expect a repetition of the combined purgation and puff which was thrust upon the public when, a few years since, the consumption of strychnia and bitter ale was stated to be in relative proportions. But what ought to become of those persons who continually take large doses, such, for instance, as the gentleman who recently recorded in the *Lancet* that he had taken thirty-five grains nightly for eighteen months?

There are others, however, who have taken notice of the enormous development of chloral hydrate manufacture. In the Customs and Inland Revenue Act, passed at the end of the last session, there is a clause providing that upon the importation into Great Britain and Ireland of any article in the manufacture of which spirit shall be used, there shall be charged upon such article, in respect of the spirit so used, a duty equivalent to that which is chargeable upon the like quantity of spirit on its importation. This, in the case of chloral hydrate, amounts, we believe, to 1*s*. 3*d*. per lb. We doubt not that the Lords of Her Majesty's Treasury will participate in the "contented satisfaction" associated by the *Spectator* with the consumption of this drug.

We have already called attention to the possible risk attending the amateur administration of this useful remedy by publishing the remarks made by Dr. Richardson on the subject. Since that time we have had to record several cases of death resulting from its improper use. We take this opportunity of republishing from the *Lancet* the following letter from Dr. Andrew Dunlop, of Jersey:—

"As a belief in the perfect harmlessness of chloral seems to be still wide-spread, perhaps you will allow me to add my word of warning to those already given, and to call attention to some alarming symptoms I have seen produced by it. On four or five occasions, after giving twenty or thirty grains of chloral, I have found that the patient slept for about a quarter of an hour, and then awoke in a state of deadly faintness; the lips livid, the face pale, and the pulse almost imperceptible. There was a sense of intense exhaustion and impending death, mingled with an indescribable delirious feeling; this lasted for about five or ten minutes. Curiously enough, one patient, as he was rallying from this state said, 'Don't give me any more of that chloroform.' He had taken chloroform a day or two before, and the sensations produced by the chloral so closely resembled his feelings on that occasion, that he thought I had given him chloroform again. Another of these patients, in addition to the other symptoms, saw figures dancing wildly round the foot of her bed. This patient had mitral disease, and was the only one of the four or five who had heart affection. As has already been indicated in the *Lancet*, by Drs. Fuller and Crichton Browne, chloral has a depressing action on the heart, and should therefore be avoided in all cases where the activity of that organ is impaired.

"While it occasionally produces ill-effects, chloral also frequently disappoints us, especially when it is given to relieve pain, or when the patient has been accustomed to opium—by acting very inefficiently, or by producing no effects at all.

"For my own part, I have found it most serviceable in cases of simple insomnia, and in the sleeplessness of phthisis and some nervous disorders."

The Editor of the *American Journal of Pharmacy*, in reprinting Mr. Hanbury's interesting historical notes on galangal,* remarks that the root is little known in American pharmacy, and perhaps never employed in the regular practice of American physicians. But it is frequently sold in various parts of the country by pedlars and travelling "medicine men" as a cure-all, or as a cure for dyspepsia, diarrhœa, headache, or toothache. During the last few years samples have been repeatedly received from localities where it had been sold under the names of China, India and East India root. Under the latter name it was recently sold in the streets of Philadelphia at about twenty-five cents per ounce,—a moderate charge as compared with that exacted in some western districts, where fifty cents per ounce, or eight dollars per pound, has been the price paid for it.

The lectureship in Materia Medica and Therapeutics at Middlesex Hospital is now vacant.

An effort is being made at Bow to limit as far as practicable the hours of labour in the pharmaceutical establishments in that locality. A circular has been issued by Messrs. Barnes, Butcher, Dean and Garman, stating their intention, after Monday next, to close at nine o'clock every evening except Saturday, when the hour will be eleven, and requesting their customers to supply their wants before those times. We hope that these gentlemen will meet with the co-operation, not only of their customers, but also of their brother pharmaceutists.

Professor Huxley will deliver the second Lecture of the course on Elementary Physiology on Monday next, at 4 p.m., at the London Institution.

Transactions of the Pharmaceutical Society.

MEETING OF COUNCIL.

November 1st, 1871.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

MR. EDWARDS, VICE-PRESIDENT.

Present—Messrs. Atherton, Betty, Bottle, Carr, Frazer, Greenish, Hills, Mackay, Sandford, Savage, Shaw, Smith, Stoddart, Sutton, Williams and Woolley.

The minutes of the last meeting were read and confirmed.

The Report of the Finance Committee was presented, showing on the General Fund Account a balance in the Treasurer's hands of . . . . £1098. 10*s.* 4*d.*
And submitting for payment sundry accounts, amounting to . . . . . . £613. 19*s.* 5*d.*
On the Benevolent Fund Account a balance of . . . . £202. 1*s.* 11*d.*

Resolved—That the Report of the Finance Committee be received and adopted and payments made.

The Report of the House Committee was presented, received and adopted.

The Reports of the Library, Museum and Laboratory Committees of the 13th and 19th October, recommending additional cases for the museum and stoves for warming the laboratory were presented, received and adopted; and the Committee was instructed to carry out the work.

Moved by Mr. Smith, seconded by Mr. Bottle,—

Resolved—That the attention of the Library, Museum and Laboratory Committee be directed to the recovery or replacement of the books missing from the Library, and that a complete catalogue of the books in the Library being desirable and necessary, the Committee be requested to ascertain the cost of printing it, and report to the next meeting of Council.

Report of the Special Committee appointed on the 6th September to consider and report on Mr. Deane's letter in reference to the condition of the Museum, Library and Specimens for the use of the Board of Examiners in Scotland.

"It is the opinion of this Committee that it is the duty of the Pharmaceutical Society of Great Britain to provide better rooms in Edinburgh for carrying on in a satisfactory way the examinations, and for the general use of the Society in Scotland; also to augment the Library and Museum there. The Committee further think that a paid officer should be appointed to perform Secretarial and other duties for the Society, under the direction of the Honorary Secretary."

Moved by Mr. Carr, seconded by Mr. Greenish, and

Resolved—That the Report of the Committee be received.

Mr. BOTTLE asked that Mr. Deane's letter should be read, and the Secretary read it accordingly:—

"*Clapham, 4th September*, 1871.

"*To the President and Council of the Pharmaceutical Society.*

"Gentlemen,—Having recently visited Edinburgh, and having availed myself of the opportunity for visiting and inspecting the rooms occupied and used by the North British Branch of the Pharmaceutical Society for conducting the examinations and for other purposes, I was much impressed with the inefficiency of the arrangements, as evinced more especially in the extent of our library and museum. For any really practical and useful purpose of study, and more especially for the proper conduct of the examinations as by law now required of the examiners in Edinburgh, they are quite inadequate.

"At the present time we occupy two rooms at No. 16, Princes Street, situated along a narrow lobby and up two flights of stairs, which are available for one day only in the week; thus precluding the majority of the members and associates from making proper use of either books or specimens. No collection, however extensive, could avail much under such conditions. Although the rooms can only be claimed by the Society one day in each week throughout the year, yet arrangements are in existence by which volumes are given out or taken in at any hour throughout the entire week; but this does not meet all the requirements of the case.

"The library consists of about 300 volumes only; and the museum of drugs, chemicals, etc., excellent and carefully kept as they are, comprises but 450 specimens; a number far below what a museum for study should be, belonging to such a Society as the Pharmaceutical Society of Great Britain, if it is desirable, as I presume it is, to sustain a high status amongst our brethren in the North, as well as amongst the medical profession in general.

"As to the collection of specimens used for the purposes of examinations, they are so defective and poor, that I can only characterize them as simply disreputable and totally unfit for the end to be attained. In stating this, I cast no reflection on our northern colleagues; they have evidently done the best with their very limited means. They most anxiously desire to be placed in a better condition, but they and I justly feel that it is not a mere local question for themselves to rectify, but one vitally affecting the interests and reputation of our body from one end of the country to the other.

"Under the existing conditions, uniformity in our examinations cannot exist, and a temptation is held out to our young men in the North of England to go where they might fancy they were least likely to be puzzled by a multiplicity of specimens.

"It should matter little whether young men went north or south of the Tweed for examination, and would not, if the conditions were the same, for one set of examiners is as well qualified as the other. It is therefore highly important that the Council of the Society should at once take active steps to remedy this defective state of our library, museum, and examining arrangements in Edinburgh.

"The suggestions I would make on the subject are as follows:—

"In the first place, suitable apartments should be taken, and properly fitted up. A flat of four rooms in some suitable locality where the library and museum should be available daily between certain hours seems desirable.

"That all duplicate books which can be spared from the London library, which the Edinburgh library does not already possess, should be forwarded as soon as the Council in Edinburgh is prepared to receive them; and that a sum not less than £ nor exceeding £ should be at once voted for the purchase of suitable books for the northern branch of our Library.

"That all duplicate specimens of drugs and chemicals which can be spared from the London museum, and which the Edinburgh museum does not already possess, should be forwarded as soon as the Council in Edinburgh is ready to receive them; and that a sum not less than £ be voted for the purchase of desirable specimens and suitable vessels for their reception.

"That a suitable selection of drugs and chemicals be at once selected and forwarded for the use of the examiners, who have a cabinet and drawers, merely requiring a few trays, ready to receive them.

"As an old examiner, and as an old member of Council, having taken a deep interest in the welfare of the Society from its foundation, I venture to place this subject before you, believing it to be one of the greatest importance, about which no time should be lost and no reasonable expense spared. It is not a question of money, nor of the numbers passing their examinations here or there; but it is one of necessity affecting our character for consistency and good sense, and of justice to those young men who have to appear before the Examiners, whether in London or in Edinburgh.

"I am, gentlemen,
"Yours faithfully,
"Henry Deane."

Moved by Mr. Hills, seconded by Mr. Shaw,—

That the recommendations of the Special Committee on Mr. Deane's letter on the North British Branch of the Pharmaceutical Society in Scotland be adopted.

Mr. Hills thought that as gentlemen and honourable men, they were bound to uphold the position so long held by the North British Branch, and hitherto so zealously and so successfully carried out in Edinburgh, and which has always been acknowledged by the Council in London.

Mr. Shaw seconded the resolution. He remembered the numerous meetings that took place in Edinburgh in connection with the matter, and he knew the difficulty Mr. Bell had in arranging the matter satisfactorily to all parties. Everything went on well; and, in 1854, it was stated, in the Annual Report of the Council to the Society, that the Board were working well in Scotland. He thought it was very desirable, seeing that the matter of the examiners was left to Scotland, that the members there should name the gentlemen whom they wished to act as examiners, and that they should every year have a communication made to them by circular, stating that a meeting would be held in Edinburgh for the purpose, and also the business to be transacted at that meeting.

Mr. Savage hoped they should elicit from Mr. Mackay whether any arrangement had been determined upon by the Local Committee, because it was very important that some arrangement should be made. They were at present paying for very inefficient accommodation a very large sum.

Mr. Woolley considered the resolution rather bare and bald. He quite agreed with the principle that the North British Branch should be conducted in a way that would reflect credit on the main Association, but the resolution committed them entirely into the hands of the North British Committee. He should like to know what sum was to be expended.

The President said no sum of money exceeding a certain amount could be expended without the sanction of the Council.

Mr. Mackay said it was now admitted that, as a part and parcel of the Pharmaceutical Society of Great Britain, the members in Scotland should be in a definite position. For a time they had very good rooms in Edinburgh, but those rooms had been required by the landlord for other purposes, and then the best was done that could be under the circumstances. They got two rooms in Princes Street, one on one floor and one on another, a state of matters causing very great inconvenience and discomfort in carrying on the examinations. With regard to Mr. Woolley's observation, he would say that not only they would not expend large sums of money, but they would only expend them under the supervision of the Council in London. It must also be remembered that although a sum of £50 was granted from time to time for the current year's expenses, those expenses had previously to the receipt of the money been partly incurred and paid. And he might further remark that in reference to the notion which had obtained as to large sums of money having been annually expended in carrying on the affairs of the North British Branch of the Society in Edinburgh, the fact was that the average annual expenditure from 1851 to the present time had only been about £62. They were, however, in the hands of the Council, and if it was said, "Go on as you have been going on," they were ready to do so.

Mr. Sandford was glad to find there was no occasion to say a word in support of the North British Branch. It seemed to be the wish of all that the affairs of the Society should be creditably conducted in Edinburgh, and at present there was not sufficient accommodation for the purpose. A complaint had been made by some gentlemen at the table that Mr. Hills' motion was not sufficiently definite, and he therefore suggested the addition of the following words:—"and that the President and Vice-President be requested to put themselves in communication with the Council of the North British Branch to ascertain what fresh arrangements are required, and at what cost they could be carried out."

Mr. Williams thought they ought to make definite laws for the management of the North British Branch.

Mr. Woolley rose to order.

The President ruled that Mr. Williams was not quite in order.

Mr. Williams desired to suggest that they should spend £20 in specimens to be sent down at once, and a committee should be appointed to draw up bye-laws and regulations for the North British Branch.

Mr. Betty thought the question was whether they should recognize the North British Branch as essentially an examining body, or whether they should consider that any educational office should be mixed up with it.

The President said the question before them was simply whether they would supply the examining Board in Scotland with proper materials and suitable premises to carry on the examinations.

Mr. Mackay said that from first to last they had never spent one single farthing of the Society's money in education, and that from 1851 to December, 1864, the Society had not paid the examiners. Courses of lectures had been from time to time delivered, but this had been done entirely at the expense of the students themselves.

The motion was then put, with the addition of the words suggested by Mr. Sandford, as follows, and carried unanimously.

That the recommendations of the Special Committee on Mr. Deane's letter on the North British Branch of the Pharmaceutical Society in Scotland be adopted, and that the President and Vice-President be requested to put themselves in communication with the Council of the North British Branch, to ascertain what fresh arrangements are required, and at what cost they could be carried out.

Moved by Mr. Stoddart, seconded by Mr. Sutton,—

That the Report of the Benevolent Fund Committee be received and adopted, and, on the suggestion of the President, that a pamphlet be prepared and published, setting forth the objects of the Fund with the names of the subscribers, donors, etc.

Moved by Mr. Savage, seconded by Mr. Edwards,—

Resolved—That John Watkins and Sarah Wilson be declared elected annuitants on the Benevolent Fund.

Resolved—That the Report and recommendations of the Parliamentary Committee be received and adopted.

Resolved—That the Registrar be authorized and is hereby instructed to remove from the Register the name of Charles Morrish.

On the Report of the Parliamentary Committee certain infringements of the provisions of the Pharmacy Act, 1868, were brought under the notice of the Council, and the Society's solicitor was instructed to take the necessary proceedings.

Resolved—That the Report and recommendations of the Provincial Education Committee be received and adopted.

A letter was read from the Honorary Secretary of the Leeds Chemists' Association, thanking the Council for their donation of £10 towards the library, and also for the monthly number of the PHARMACEUTICAL JOURNAL.

Resolved—That Alfred Franklin and John E. Griffith be appointed Local Secretaries to the Society at Fareham and Bangor respectively.

COLLECTOR FOR 1872.

Mr. Lancelot Steele Hughes was reappointed Collector for the ensuing year.

REPORTS OF THE BOARDS OF EXAMINERS.

October, 1871.

ENGLAND AND WALES.

Examination.	Candidates examined.	Candidates passed.	Candidates failed.
Major	7	5	2
Minor	36	17	19
Modified	34	23	11
Preliminary	222	140	82
	299	185	114

SCOTLAND.

Examination.	Candidates examined.	Candidates passed.	Candidates failed.
Major	1	1	0
Minor	11	7	4
Modified	4	3	1
Preliminary	19	18	1
	35	29	6

Resolved—That the following having been duly registered as Pharmaceutical Chemists, be respectively granted a diploma stamped with the seal of the Society:—

Browne, Joseph Alleyne...... London.
Gibson, Adam .... Dunfermline.
Gill, Joseph William .... Pendleton.
Maddock, William Thomas .. London.
Marks, Benjamin .... Plymouth.
Woolley, Harold .... Manchester.

Resolved—That the following registered Chemists and Druggists in business before the 31st July, 1868, be elected Members of the Society:—

Hudson, Robert Spear........ West Bromwich.
Pershouse, Edward .... West Bromwich.
Smith, Edgar Rayner .... Stafford.

Resolved—That the following having passed the Minor Examination, be elected Associates of the Society:—

Brown, Richard Fearon ...... London.
Caswell, Thomas George .... Dudley.
Gardner, James Richard...... Devonport.
Jameson, William Edward.... Bristol.
Marshall, Alfred .... Hornsey.
Redfern, John .... Oxford.
Tamplin, Charles Edward .. Kingston-on-Thames.
Williamson, Joseph Burrell .. Edinburgh.

EXAMINATION IN LONDON.

October 27th, 1871.

Present—Messrs. Allchin, Barnes, Bird, Carteighe, Cracknell, Davenport, Edwards, Gale, Garle, Haselden and Ince.

MODIFIED EXAMINATION.

Thirty-four candidates were examined; *eleven* failed, the following *twenty-three* passed, and were declared duly qualified to be registered as

CHEMISTS AND DRUGGISTS.

Ashton, Alfred .... Kennington.
Bailey, Edward Smith........ Brighton.
Carman, John .... Chester.
Cavell, John .... Long Sutton.
Dubois, Bernhard William.... Brixton.
Griffits, John Alonza .... Wantage.
Harrison, Thomas Evison .... Lincoln.
Hickman, Frederick .... Southampton.
Howe, Joseph Mason .... Dublin.
Huxtable, James .... London.
Owen, William.............. Pwllheli.
Parkin, Thomas .... Hereford.
Sansom, Henry.............. Hitchin.
Smith, James Malcolm ...... Doncaster.
Stevenson, Richard Walter.... Derby.
Taylor, Alfred .... Kendal.
Tijou, Tom .... Kettering.
Vickers, Thomas .... Beverley.
Waller, Robert .... Doncaster.
Womack, Thomas............ Barnsley.
Woolrich, Francis............ Uttoxeter.
Wright, Arthur .... Nottingham.
Wrighton, Thomas H. Garland. Birmingham.

PRELIMINARY EXAMINATION.

Certificates were received from the undermentioned in lieu of this examination:—

Miller, Ernest John.......... Melbourne, Royston.
Plowman, Sydney .... Boston.

EXAMINATIONS IN EDINBURGH.

October 17th, 1871.

Present—Messrs. Aitken, Buchanan, Gilmour, Kemp, Noble and Young.

MAJOR EXAMINATION.

The following gentleman was examined, and was declared duly qualified to be registered as a

PHARMACEUTICAL CHEMIST.

*Gibson, Adam .... Dunfermline.

MINOR EXAMINATION.

Eleven candidates were examined; *four* failed, the following *seven* passed, and were declared duly qualified to be registered as

CHEMISTS AND DRUGGISTS.

*Green, Thomas.............. Belfast.
*Mellor, Thomas .... Bury.
Anderson, Alexander .... Elgin.
Williamson, Joseph Burrell .. Edinburgh.
Hinksman, John .... Edinburgh.
Edward, William Wales...... Aberdeen.
Linklater, James .... Edinburgh.

The above names are arranged in order of merit.

PRELIMINARY EXAMINATION.

Nineteen candidates were examined; *one* failed, the following *eighteen* passed, and were declared duly qualified to be registered as

APPRENTICES OR STUDENTS.

Mathie, William .... Edinburgh.
King, George .... Elgin.
Thomson, Robert .... Stirling.
Grant, R. J. .... Elgin.
Daniel, James .... Stonehaven.

* Passed with honours.

Equal.	Gilmour, James	Edinburgh.
	Reid, James	Edinburgh.
	Davidson, James	Falkirk.
	Blanshard, Richard Lacy	Edinburgh.
	Gray, James	Edinburgh.
	Tweedie, Alexander	Edinburgh.
	Macintosh, John	Elgin.
	Ellis, Thomas Russell	Dunfermline.
Equal.	Gibson, Aikman Graham	Edinburgh.
	Ogilvie, John Hovel	Montrose.
Equal.	Dick, Robert G.	Edinburgh.
	MacGregor, Donald	Edinburgh.
	Stuart, Thomas Peter Anderson	Dumfries.

The above names are arranged in order of merit.

MODIFIED EXAMINATION.

Four candidates were examined; *one* failed, the following *three* passed, and were declared duly qualified to be registered as

CHEMISTS AND DRUGGISTS.

Dickinson, Joshua Steel	Newcastle-on-Tyne.
Sinclair, George Fisher	Liverpool.
Wright, John Armstrong	Macclesfield.

PHARMACEUTICAL MEETING.

Wednesday, November 1st, 1871.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

The following Donations to the Library were announced:—

Calendar of the Royal College of Surgeons, of England, 1871,—University College, London, Calendar, Session 1871–72,—Transactions of the Clinical Society of London, Vol. IV.,—Statistical Tables of the Patients under Treatment in the Wards of St. Bartholomew's Hospital during 1870,—La Viande des Animaux malades au point de vue de l'Alimentation publique, par M. T. Hetet: from the "Société d'Acclimatation."

The thanks of the Meeting having been accorded to the several Donors, the PRESIDENT then called upon Mr. J. B. Barnes to read a paper on "A New Excipient for Pills," which will be found printed at p. 361.

At the conclusion of the paper,

The PRESIDENT said that this was a very appropriate pharmaceutical subject, and one upon which he imagined they must all have some notion, if not much experience. He very much disliked ever having to find fault from that chair, but he had told his friend Mr. Barnes that he demurred to the practice of putting these medicines into pills. Pills might be very convenient at times, but as a general rule he thought they should endeavour, if possible, to put these remedies in some other shape, especially the hydrate of chloral. He considered it very objectionable to put hydrate of chloral into pills, which might be swallowed almost *ad libitum*, and they scarcely knew what the consequences might be. With respect to sulphur, he thought there could be no great objection to the pill system. Having looked into the specimens of pills before them, he certainly must say that they were very ingeniously and cleverly put together; and if at any time pills of that kind should be required, there could not possibly be anything better than those which Mr. Barnes had placed upon the table. They should at all times give encouragement to gentlemen who brought forward these modified, or what they conceived to be improved, conditions for making medicines, although, as one of the old school, he objected to pills when he could give the medicine in the shape of draughts. He should be very glad to hear expressions of opinions from gentlemen in the room who had had more experience in this matter than he professed to have.

Professor ATTFIELD would like to ask Mr. Barnes, by way of introducing the discussion, whether he had made any experiments as to the relative rate of solubility of these pills. He remembered that some time ago Mr. Morson brought before their notice some so-called soluble cream of tartar which had solidified, and which subsequently, he thought, was found to be not so readily miscible with water as the ordinary more fluid preparation. It was possible that the tartar in these pills might be in a similar condition. At all events it was important to know at what rate pills dissolved.

Mr. BARNES replied that he found the pills dissolved in a very short time when placed in tepid water, perhaps, on the average, in about ten minutes.

Mr. LINFORD thought this question rather brought up the idea whether the reason for putting these medicines into pills was that their action might be more gentle or more modified on the system. He did not know whether members had experimented on the difference to be obtained with such substances as scammony resin, or jalap, in this direction. Their duty was to prepare medicines ordered by medical men, but in that preparation they ought to look somewhat to the subsequent action upon the system, and it was a question whether the real end and purpose of putting these things into pills was not that, by their being gradually dissolved, their action might be correspondingly modified.

Mr. J. E. HOWARD, F.L.S., then read a paper on "Cinchona-trees grown in India," which will be found printed at p. 361.

The PRESIDENT said that this was a very important communication, and one in which they all, no doubt, took great interest. It was possible that some of the gentlemen present might be able to offer some further remarks upon the subject. There was only one point that struck him as being a mercantile question of some importance, and that was why the Government should have encouraged the growth of the *succirubra* barks in preference to the *Calisaya* barks, seeing that the latter produced a larger amount of quinine—so much used in this country—than the other. He had been told by a commercial gentleman who dealt largely in these articles that it appeared to be a mistake on the part of the Government that they had undertaken to grow, and had grown, the *succirubra* barks instead of the *Calisaya* barks. He personally was quite inexperienced in the growing of these barks, but still it struck him as a curious fact that the Government should have grown the Succirubras, which were seldom used nowadays. Occasionally, it was true, a physician ordered *succirubra* bark in an infusion or a decoction, but the general thing was *Calisaya* bark, both for quinine and in nearly all the preparations they used in pharmacy. Perhaps some gentleman could enlighten them upon the subject. Professor Bentley was present, and probably he would kindly say something on the point to which he had referred.

Professor BENTLEY said that, having been called upon, he would express the pleasure he felt in hearing the paper with which they had been favoured, for they always looked to Mr. Howard for any information upon the subject of barks, which he had certainly made peculiarly his own, not only in this country, but in all parts of the world. He (Professor Bentley) should not have risen on this occasion if he had not been appealed to by the President. If he understood properly, Mr. Howard spoke particularly of the great development in the cultivation of the *Cinchona succirubra* in comparison with *Cinchona officinalis*, and he also thought Mr. Howard had said that there was a larger development of the bark of the *officinalis* than of the *succirubra;* but he did not understand that

Mr. Howard wished to draw any practical result from that, or imply that there was any particular reason for growing *succirubra* in preference to *officinalis*. He should like to know whether the results obtained were founded upon a simple examination of one or two plants, or whether they were arrived at by the examination of a number of plants, because every one who knew anything about the development of plants would agree with him, that two plants selected promiscuously would not yield any special result which could in any way be depended upon. There was another question in which he felt particularly interested. Some years ago Mr. Howard favoured them with an examination of the root-bark of certain plants of *Cinchona calisaya*, and there was great difference of opinion in regard to the matter; Mr. Howard showing that the root-bark was very much inferior in every respect to the stem-bark. But this result was afterwards called in question, or rather, certain other investigators came to a different conclusion. If he rightly understood Mr. Howard's paper that evening, it was to this effect, that no special examination was made of the root-bark, because it was too thin. If, however, he had made any such examination, it would be very interesting to know the comparative value of the root-bark and the stem-bark, not only as bearing upon the particular views which Mr. Howard had always held, but as bearing on those different alkaloids or different parts of the bark which were of great importance to those who took an interest in physiological botany.

Mr. Howard remarked that, in reference to the different species of Cinchona, he had always urged upon the Government the securing, in the first place, of all the species they could get from South America, and giving them all a fair trial under different circumstances. One species would develop much more rapidly in bog earth perhaps, while another would develope in loam. *Succirubra* would develope well in loam. Of course the climate had great influence on these trees, which were peculiarly susceptible of influence from light and climate in various ways. His object had therefore been that the Government should not confine their attention to *Cinchona succirubra*, but that they should devote it to other species in proportion as they were found to be valuable. The object of his paper was, partly, to enforce that view of the subject; and he showed that the *succirubra*, though so rapid in its development, was not so good as the other. He had not had an opportunity of examining the *Calisaya* upon so large a scale, but it was a better tree, although very delicate in its predilections; and he scarcely knew what to say about the success of, that species. He had seen specimens from Darjeeling which looked exceedingly good, although they did not bear out the full idea he had formed from the appearance. He did not know why. With reference to Professor Bentley's question, he remarked that he had not had any very great experience in the barking of the roots; and, therefore, what he had said about root barks must be taken as founded on a limited experience. When the roots run under moss, he had no doubt the bark on them would be very rich; but it was very different otherwise, for when the roots penetrated deeply into the ground it was thin and worthless. Mr. M'Ivor succeeded in getting the greatest products from roots covered with moss, and he (Mr. Howard) had no doubt Dr. De Vrij was right in that respect, and to him he readily yielded the palm.

Mr. Brady said he would propose a vote of thanks to Mr. Howard for his excellent paper, in order that he might, by a sort of side wind, have the opportunity of saying two or three words upon the subject which had been introduced to their notice. He apprehended there was no one present who had a right to speak critically concerning cinchona barks or their products after Mr. Howard had spoken. Some years ago he had an opportunity, partly through the kindness of Mr. Howard, of following certain of that gentleman's researches in connection with the microscopical structure of cinchona barks, and since that time he had accepted with implicit faith everything that Mr. Howard said in connection with them. He had been asked by the editors of the Pharmaceutical Journal to review Dr. Berg's 'Anatomischer Atlas zur pharmazeutischen Waarenkunde,' and he had then been led to examine critically the microscopical structure of a considerable number of the varieties of barks found in commerce. It was well known to them that the late Dr. Berg, of Berlin, had opposed Mr. Howard's views relative to the condition in which the alkaloids occurred in these barks. Dr. Berg's researches were followed by Delondre, by Phoebus and others, with some confirmation; but he was bound to confess that, having investigated the subject with all the care that he could, he came to the conclusion that Mr. Howard was entirely in the right. It was only due to Mr. Howard, who was kind enough to supply him with part of the specimens which had come under his examination, to make this acknowledgment; and, to put himself in order, he would now move that their cordial thanks be given to Mr. Howard for this and his other contributions to the history of cinchona barks.

The President said it was unusual to put a vote of thanks in the course of the proceedings, but on the present occasion he felt great pleasure in being called upon to put such a resolution, because he felt, as he had no doubt they all did, that they were greatly indebted to Mr. Howard for everything he brought before them in connection with cinchona barks.

The resolution having been cordially agreed to,

Mr. Howard briefly acknowledged the compliment, and took the opportunity of saying that his views on the points alluded to had been confirmed latterly by Mr. Broughton in India and M. Carles in Paris.

Pharmacy in America.

The President mentioned that, according to the programme of the evening's proceedings, Mr. Greenish would read a paper upon "Pharmacy in North Germany;" but previously to doing so, perhaps they would permit him (the President) to mention that they had present that evening a gentleman who lived at a great distance from the metropolis, and whom, consequently, they did not often see amongst them. He alluded to Mr. Brady, who had just returned from America, where he had seen and heard a great deal in connection with pharmacy; and he should feel much obliged to that gentleman if he would give them that evening some account of his journey and reception on the other side of the Atlantic.

Mr. Brady said that he would not question the right of the President to change the ordinary course of business by calling upon an inconspicuous pharmacist to give his experience on some entirely foreign subject, but he really scarcely knew what to say, or what was expected of him. It was true that he had been to America and only recently returned, and that his object in going there was, in part, to attend the meeting of the American Pharmaceutical Association, a body which, as they knew, resembled in many respects the British Pharmaceutical Conference rather than the Pharmaceutical Society of Great Britain. He did not know how he could muster the presumption, with his friend Mr. Howden in the same room, to offer any observations about American pharmacy. Was it not all written in the chronicles of their Journal? Did not Mr. Howden read in that room a most elaborate discourse on the condition of pharmacy in America, which, if he recollected rightly, was considered so important that a second meeting was called to discuss it? He had no idea half an hour ago that he was going to be called upon to make any statement with regard to his American visit; indeed, he thought that, having travelled all night, without the advantage of a "sleeping-car," he should have been allowed to go quietly to bed. And now he had been called upon to speak of pharmacy in America. Had they any idea what pharmacy in America was? Pharmacy in England was represented by a district some 600 miles from end to end; but to speak in any general terms of pharmacy in the great continent of America would, unless one had very full time for consideration, a very long paper to do it in, and a very patient meeting to read it to, be simply an absurdity. And yet pharmacy in America was very similar to pharmacy in England. Take it all in all, he did not find in the few weeks he spent in the United States, any very marvellous difference between the pharmacy or pharmacists of the two countries. It had been told to one or two of the American pharmacists that he, in a semi-official capacity, purposed to visit the United States and to attend the meeting of the American Pharmaceutical Association in St. Louis. Almost before his baggage had passed the Customs House, he was saluted by a pharmacist of New York, who had come down to the landing stage to meet him, and to see that he was comfortably provided for. And from that moment till the time of his departure he never ceased to experience their kindness and their thoughtfulness. That was the best testimony he could give to pharmacy in America. But here they were met to consider pharmacy in a somewhat different aspect from its relation to hospitality, and hence came his embarrassment. He scarcely knew, unless they would tell him, upon what salient points of pharmacy he was to speak. Mr. Howden had told them, in far better language than he could command, what pharmacy was as a business throughout the States; and he (Mr. Brady) feared that if he went into matters of pharmaceutical science without deliberation, he should only come to grief. Whilst he was in America he saw something of pharmacy in, perhaps, the six largest cities of the Union,—in New York, Brooklyn, Philadelphia, Boston, Baltimore, St. Louis, and Chicago; and he did not find amongst the leading pharmacists, amongst whom he had the pleasure chiefly of moving, any great difference from the same class of men in half-a-dozen of the largest towns in England and Scotland. There were some differences, but these were in matters of detail, depending on the somewhat altered conditions of life. He must, therefore, if he were to say anything, talk about the meeting of the Pharmaceutical Association in St. Louis, because, in that respect he had his one advantage over Mr. Howden. At the meeting at St. Louis he found assembled the leading pharmaceutists of America, men whom they all knew so well by name,—Professors Proctor, Parrish, Maisch, Ebert, Bedford, and the rest; and was delighted to find one representative of Great Britain besides himself, Mr. Saunders, of London, Ontario,—a better man to represent the Dominion of Canada in the Pharmaceutical Convention of America there could not be. The Convention at St. Louis did not differ so very much from one of those Conferences which many present had the pleasure to attend from year to year in Great Britain. Papers were read, discussions indulged in, a large amount of social entertainment took place, in fact, it was just one of those occasions that seemed calculated to make pharmaceutists think a great deal better of each other; it was a gathering eminently qualified to make head against the tendency that trade had to make one forget professional etiquette. He did not wish to make comparisons, because the American Pharmaceutical Association did not represent exactly the British Pharmaceutical Conference. The American Association represented the United States as a whole; therefore, if they compared the results shown at one of these conventions with the work done in England during the year, they must take the work of the Pharmaceutical Society and the Pharmaceutical Conference jointly as representing Great Britain. And really he was very glad to find that there was some mitigating circumstance of that sort, because the amount of good, solid earnest investigation, the results of which were brought forward at the four days' meeting in St. Louis would, he confessed, have made him feel just a little doubtful in making a comparison between that meeting and a meeting of the British Pharmaceutical Conference. He would mention specially the amount of valuable research that was brought forward in their "Reports," such as, for instance, that on the Progress of Pharmacy, or the Report on the Drug Trade, or that on Adulterations and Sophistications which were brought forward at the meeting, and he did not know that in England they could show anything parallel to them. He regretted to have to say so, but it would not be right towards this Society, nor just to them, to withhold it. There were some points—and upon these special points he did not intend to speak—in which he rather preferred English ways to American. He went to America to see, to listen, and to learn; and he trusted that, if he had learned aught, when the events of the last two or three months had come to something like a reasonable focus in his brain, he might be able to speak better about them. But, at present, he could think of little except the kindness, the consideration, the constant welcome he received, the inquiries after pharmacists in England, the delight evinced in hearing of any success that had come to pharmacy in this country, and of the brotherly feeling displayed in every possible way, and on every occasion, whilst he was amongst their friends in America.

The President remarked that, after what they had heard, he was sure they would not find fault with him for having suggested that Mr. Brady should address them that evening.

Mr. Thomas Greenish, F.C.S., then read a paper on "Pharmacy in North Germany and Austria," which will be found printed at p. 363.

The discussion on Mr. Greenish's paper was deferred to the next meeting; and, in addition to this discussion, the President announced that papers would be read on "The Substitution of Proportional Numbers for Specified Weights and Measures in the Description of Processes in the Pharmacopœia," by Professor Redwood, and on a "Method for the Estimation of Morphia in Opium," by Mr. John T. Miller.

The meeting then adjourned to Wednesday, December 6th.

Provincial Transactions.

HULL CHEMISTS' ASSOCIATION.

The Third Annual Meeting of this Association was held at the Cross Keys Hotel on the 19th of October. The Secretary having read the report and the balance sheet for the past year, the adoption of the same was moved by the President (Mr. Baynes), and seconded by the Vice-President (Mr. Smith).

The election of officers for the ensuing year was then proceeded with, when Mr. A. Pickering was elected President, Mr. H. Smith, Vice-President, Mr. C. B. Bell, Hon. Sec. and Treasurer, and Messrs. Stanning, Baynes, Earle and Myers, on the Committee.

Cordial votes of thanks were accorded to the retiring officers for their services during the past year, which were respectively acknowledged.

The chemical and materia medica session will commence on Thursday evening, the 26th of October, at the Society's room in the Church Institute: lecturer, W. A. Rudd, Esq., M.R.C.S.

LEEDS CHEMISTS' ASSOCIATION.

The Annual Meeting of this Society was held in the library on Wednesday, October 25th, 1871; the President, Mr. Smeeton, in the chair.

The minutes of the last meeting having been read and confirmed, Messrs. T. M. Mitchell, J. R. Richardson and Crampton were elected associates.

Mr. E. Thompson, Vice-President, read the report as follows:—

Your Committee have to report that during the past session papers have been read as follows:—The President's Address,—History of a Fungus, by Mr. James Abbott,—On Dispensing, or who ought to do it, by Mr. J. L. Roberts,—On the Preparation of Vin. Ferri, by Mr. James Abbott,—On Sp. Ammoniæ Co., by Mr. F. Reynolds. These papers were very interesting and instructive, and afforded excellent opportunities for discussion.

The fourth meeting of the session was occupied in considering the proposed regulations for the storage of poisons, introduced again by the Council of the Pharmaceutical Society, and your Committee invited all the chemists and druggists in business in this town, thus giving them an opportunity of discussing the question. Whilst regretting the meagre response to this invitation, your Committee feel confident that the zeal and energy with which the few present opposed the attempt to make these regulations compulsory, was heartily appreciated by the trade. The feeling of chemists throughout the country coincided so thoroughly with this opinion that the Council of the Pharmaceutical Society withdrew from the attempt to pass compulsory regulations upon the storing of poisons. Soon after this, Dr. Simon introduced into Parliament a Pharmacy Bill, the essential objects of which were to enforce, under penalties, the storing of poisons and to compel the use of a special poison bottle. This measure roused an opposition from the whole body of chemists throughout England and Scotland, such as has never been elicited by any other question. In the organization needful to represent this feeling the chemists of Leeds took their share with the greatest unanimity of feeling, and employed their party influence with an effect that gave them the greatest encouragement. The Committee trust that the energies of the members may in future be used more profitably than in thus defending their body from uncalled-for and mischievous interference, but should the emergency again arise, the Committee are confident that the feelings of the chemists of Leeds will be expressed with similar earnestness.

Financially, the past session has been a success, the introduction of cheap postage and the collection of subscriptions by Mr. Roberts and some of the Committee, having tended to the interests of the Society. The amount saved in the cost of a room for the monthly meetings is not quite so satisfactory, as showing the limited attendance. It is hoped the necessity of being firmly cemented together, as proved during the struggle against the proposed Pharmacy Bill, will be the means of causing a better attendance at these meetings for the future.

In consequence of private engagements, Mr. Roberts, who kindly offered his services as Secretary last year, has intimated that he cannot continue the office another year. Your Committee acknowledge the zeal and earnestness with which Mr. Roberts has conducted the business of the Society.

Your Committee have reason to hope that Mr. Yewdall, who has so efficiently performed the duty of Secretary almost uninterruptedly since the commencement of the Society, may be induced again to accept the office which ill-health alone compelled him to resign.

The following donations to the Library and Museum have been made during the past year:—The Pharmaceutical Journal, monthly: from the Council of the Pharmaceutical Society,—Specimens of the Organic Constituents of the British Pharmacopœia: from Messrs. Southall, Son and Dymond, Birmingham,—A Glass-case to hold Materia Medica Specimens: from Mr. Reynolds. The following periodicals have been regularly supplied to the Library:—The *Chemist and Druggist*, *Chemical News*, *Nature*, and *Science Gossip*.

During the past year an additional Book-case has been erected, and your Committee have to acknowledge a special donation of ten pounds from the Council of the Pharmaceutical Society, to be expended in the purchase of books. These books are now upon the table, and will be considered a valuable addition to our already carefully selected Library.

Your Committee arranged with Mr. Abbott to deliver a course of twenty lectures upon botany in the Library, the attendance being very satisfactory. Chemistry classes have been held in the Mechanics' Institution by Mr. George Ward, F.C.S., and at the Young Men's Christian Institute by Mr. Jeffreson, F.C.S. Associates of the Society have the privilege of attending these lectures at the lowest fees.

Your Committee believe that the objects of the Society have been thoroughly maintained, and trust its usefulness will be the means of bringing additional members and associates into our ranks.

The Treasurer's account was also presented, and showed a balance of £7. 6*s.* 7½*d.* in favour of the Society.

Mr. R. M. Atkinson proposed the adoption of the Report, and regretted the meagre attendance. He thought that too much had been done for the associates and too little for the members; and he hoped the Committee would endeavour to make the meetings attractive to the members as well as associates. He thought an effort should be made to induce the retail chemists to close earlier, and if such a desirable course could be adopted, he had no doubt the meetings would be better attended.

Mr. James Abbott seconded the motion, and re-echoed Mr. Atkinson's remarks respecting the attendance. He hoped the present session would be an improvement upon the last in this respect.

The motion was carried unanimously.

The election of officers for the ensuing year was then proceeded with, and the following declared elected:— *President:* Mr. E. Brown. *Treasurer:* Mr. J. Land. *Curator:* Mr. E. S. Payne. *Librarian:* Mr. T. Wilson. *Honorary Secretary:* Mr. E. Yewdall. *Committee:* Messrs. Wm. Smeeton, J. Day, F. Reynolds, T. B. Stead, J. Beedle, E. Atkinson. *Auditors:* Messrs. George Seley and J. Longfield.

In vacating the chair, Mr. Smeeton acknowledged the kindness shown by all connected with the Society during the time he had held office as President. He recommended that this Society, and all other kindred institutions, should offer greater facilities for young men than at present. Why should not associates of this Society be able to go before the examiners and pass their examinations creditably, without going to Bloomsbury Square? They had great facilities at present, and he had no doubt the Committee would endeavour to provide for any deficiency that was found to exist.

Mr. E. Brown, having taken the chair, thanked the members for intrusting him with their confidence by electing him to the office of President. He assured them that he had little time at disposal for such a responsible office; and had he not been satisfied those who were elected to work with him would render great assistance, he should have shrunk from the duty. He thought that they were doing much to assist young men to pass the examinations. They had in Mr. Megilley's class a means whereby youths could be prepared for the Preliminary Examinations, and in Mr. Abbott's botany class the associates had an excellent opportunity of becoming acquainted with this science. He had great pleasure in proposing, "That the best thanks of the Society be given to the retiring officers."

This resolution was seconded by Mr. Anderson (associate), and carried unanimously.

Mr. Smeeton briefly acknowledged the compliment on behalf of those who had been associated with him during the past year.

Mr. J. Day proposed, "That the best thanks of the

Society be given to the Council of the Pharmaceutical Society for the special grant of ten pounds, and also for the PHARMACEUTICAL JOURNAL (monthly) to the library, which was seconded by MR. E. THOMPSON, who took occasion to remark that he could not quite endorse the opinions which had been expressed by previous speakers with respect to the education of the young men. In the well-appointed laboratories of the Mechanics' Institution and Young Men's Christian Institute, so ably conducted by two members of our Society, he thought the young men connected with the trade had excellent opportunities afforded for making themselves acquainted with theoretical and practical chemistry,—such facilities, indeed, as we could not offer except at a great outlay of capital, which would not be remunerative. It would be quite in accordance with the objects of our Society to continue the lectures on botany.

MR. RHODES moved, and MR. YEWDALL seconded, a vote of thanks to Mr. Reynolds, F.C.S., for the gift of a glass case to hold materia medica specimens, which was carried unanimously.

In conclusion, MR. HIGHMORE (associate) urged the Committee to endeavour to obtain shorter hours of business.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

The Monthly Evening Meeting of this Association was held on Thursday evening, the 26th of October; the President, MR. GEORGE DYMOND, occupied the chair. There was a large attendance, the reading-room being quite full.

In introducing the paper of the evening, by Mr. William Southall, the PRESIDENT remarked that the subject was one which could not fail to interest those who were present who had yet to submit to the ordeal of examination. So far, however, from regarding a preparation for the examinations of the Pharmaceutical Society as an oppressive burden, he thought that a just view of the advantages of study in its effects upon the mental powers, and of the benefits to be gained in the acquisition of knowledge, should stimulate the student, whose life would thus be raised above the mere drudgery of the shop and ennobled by high and worthy aims, whilst an additional motive might well prompt his endeavours in the reflection that his studies had for their ultimate object the mitigation of human suffering.

[We purpose printing Mr. Southall's paper *in extenso* in next week's issue.—ED. PHARM. JOURN.]

VACANCIES AND APPOINTMENTS IN CONNECTION WITH PHARMACY.

The Editor will be glad to receive early notice of any vacancies of pharmaceutical offices connected with public institutions, and likewise of appointments that are made, —in order that they may be published regularly in the Journal.

APPOINTMENTS.

Mr. James Richard Gardner, A.P.S., has been appointed Assistant Dispenser at the Royal Naval Hospital, Plymouth, *vice* Mr. Benjamin Marks, Pharmaceutical Chemist, appointed Dispenser and Medical Storekeeper at the Royal Naval Hospital, Chatham.

The following journals have been received:—The 'British Medical Journal,' Oct. 28; the 'Medical Times and Gazette,' Oct. 28; the 'Lancet,' Oct. 28; the 'Medical Press and Circular,' Nov. 1; 'Nature,' Oct. 30; the 'Chemical News,' Oct. 28; 'English Mechanic,' Oct. 27; 'Gardeners' Chronicle,' Oct. 28; the 'Grocer,' Oct. 28; the 'Journal of the Society of Arts,' Oct. 28; the 'British Journal of Dental Science' for November; the 'American Chemist' for October; the 'Journal de Pharmacie et de Chimie' for September; 'Zeitschrift des allgemeinen österreichischen Apotheker-Vereines,' October 20; 'Neues Repertorium für Pharmacie,' Sept. 9; the 'Chloralum Review' for November; 'Evans, Lescher and Evans' Monthly Price Current.'

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

PROVINCIAL EDUCATION.

Sir,—A few facts may possibly assist the successful theorizing of some of your contributors in reference to Provincial Education; I regret that those I have to communicate are painful ones, since they relate but to failure and disappointment.

In the autumn of 1868, when the requirements of the Pharmacy Act were fresh in all minds, the Manchester Chemists' Association established classes in chemistry, materia medica and Latin; 62, 58 and 49 entries were respectively made in these, and a good average attendance was obtained; encouraged by such a ready response, we applied to Owens College for co-operation, and a special course of instruction for pharmaceutical students was arranged. Our lecturers were, on Chemistry, Mr. Schorlemmer, F.R.S.; on Botany, Professor Williamson, F.R.S.; on Materia Medica, Mr. Somers (now and for many years past lecturer on the same subject in the Manchester School of Medicine), and on Latin, Professor Wilkins, M.A. The fee was 15*s.* per course of twenty-seven lectures, with a considerable reduction in the case of those who attended several classes. The ardour of our students had, however, cooled, and comparatively small classes were formed. The following session renewed efforts were made by our Association, a special course on pharmacy was added, an accomplished local pharmacist, Mr. Louis Siebold, being appointed lecturer; nevertheless, our classes dwindled, and this session we have been obliged to close those on pharmacy and materia medica, because the minimum number of entries (10) could not be obtained. The chemistry, botany and Latin classes continue working, being open to other than pharmaceutical students. Here is another "mournful sentence" for Mr. Ince. Can he point out who is to blame? Our lecturers were men of undoubted ability, and enthusiastic teachers; we were connected with one of the most eminent science schools of the kingdom; and our prizes were distributed by the Lord Bishop of Manchester! What more could our students desire?

For myself, I believe the causes of our failure to be many, but chiefly, I fear, the disinclination of young men to enter upon the serious study of the various subjects in our curriculum,—a putting off of the evil day, in the hope that something may turn up to relieve them from the necessity of meeting it, and a trust in the vaunted powers of "rapid preparation" men to assist them at the eleventh hour if need be. Some of them have discovered that mere attendance at lectures does not qualify them for the examinations; and as they have not been accustomed to regard the acquirement of knowledge for its own sake as desirable, but only as a means to an end, that end being the examinations, they are dissatisfied with what appears to them the indirectness of the means, complaining that the Latin taught is not "pharmaceutical" Latin, nor the chemistry "pharmaceutical" chemistry, etc. But can we expect young pharmacists to be wiser than young doctors, or other young men? Cramming is one of the evils of our day, and it will test the skill of our examiners to find out where it has been resorted to, that they may do the candidates the kindness of sending them down. Professor Huxley recently said in Manchester that he had had the satisfaction of plucking sixty out of seventy papers from one school where he knew cramming was practised. Let our own examiners follow this good example, and we shall soon have less of it, and more healthy study amongst our assistants and apprentices. Some excuse must be made for those who were engaged in the business before 1868, and were taken unawares by the Pharmacy Act. For them the Minor might, perhaps, be a little relaxed; but those who have deliberately joined our ranks since that date should feel it an honour that so much is expected of them. That some of the responsibility of our failure rests with the masters I doubt not,—the relation of master and apprentice is scarcely yet adapted to the new pharmaceutical era. The importance of getting well-educated apprentices has been frequently alluded to; equally important is it to the progress of pharmacy that the apprentice gets a good master, one who, though he may not, for one or many reasons, personally undertake the teaching of all that his apprentice has to learn, shall at least afford him opportunities for study, and encourage him by a kindly interest in his work at a time when sympathy is so powerful an influence for good.

It is but poor consolation to find from the reports of some other local Associations that we in Manchester are not alone in our disappointment. We are discouraged, but not without hope. We feel assured that by avoiding anything like "special preparation" classes we have done rightly, and we now await a possible kindling of the desire for knowledge which is something far different from the mere wish to get through examinations.

Market Place, Manchester. F. BADEN BENGER.

Sir,—Although Mr. Mason in his letter on provincial education, which appeared in last week's Journal, expresses his concurrence with Mr. Smith's first and third propositions, his objection to the third would nullify the entire plan, for in that proposition is enunciated the principle upon which the details of the scheme rest, and it appears to me that, as far as it goes, the principle is perfectly just. It maintains, as I understand it, that as it is compulsory for every member of the trade to pass the Minor before opening a business, so it is a necessity to provide means for him to do this.

But I apprehend there would be no necessity for the local associations, as educating bodies, to limit their teaching to Minor subjects, only whatever was done further it could not be expected would be supported to such an extent by grants from the Pharmaceutical Society.

Mr. Mason seems alarmed lest, having passed the Minor, the apprentices should be contented to rest on their laurels, and it does certainly appear that there are some grounds for his apprehension. But the line of action which he indicates when he says that the course of teaching should be without reference to any examination, would not have so good a chance of success as would a course of preparation for the Minor with the teachers endeavouring to interest their pupils in the subjects. This might lead to their pursuing study for the very love of it. Besides this, Mr. Mason must forget that the success, and, indeed, the existence, of provincial associations depends upon the attendance of apprentices; and if these latter cannot find in the course of study provided for them a direct bearing upon the Minor, they will terminate their connection with the Association, and fall back upon an actual cram at home, thereby bringing to pass the very evil he would prevent, as well as leading to the breaking up of the Association.

Norwich, October 25th, 1871. E. NUTTALL.

THE PRELIMINARY EXAMINATION.

Sir,—On looking over the Journal of Saturday last, 21st inst., I noticed the large amount of failures in the Preliminary Examinations, the number of which is sufficient to astound the most unthoughtful of our learned body; but more particularly is the fact conspicuous in the glaring result amongst the candidates examined in the largest towns, and I am led to ask, "How can these things be?"

I will take, for instance, the undermentioned cities and towns, viz.:—

	Candidates examined.	Candidates passed.	Candidates failed.
London . . .	30	9	21
Manchester . .	9	3	6
Birmingham . .	2	0	2
Derby	4	2	2
Peterborough .	4	0	4
Swansea . . .	5	0	5
Taunton . . .	4	0	4
Aberdare . . .	3	0	3
Aberdeen . . .	5	1	4
Carmarthen . .	3	0	3
Chester . . .	3	0	3
Wolverhampton	2	0	2
Total . .	74	15	59

I find, upon consideration, that twelve cities and towns have contributed fifty-nine out of eighty-two failures. The above twelve may be branded, without any illwill whatever, with the significant words, "Weighed in the balance and found wanting." I would ask all connected with the Society the why and the wherefore of these lamentable statistics. How many of the candidates examined in London and Manchester reside in those two places? for I cannot conceive of the majority, being engaged in business in those two places,—having the privilege of such abundant facilities of education, enjoying the advantage of every necessary work to enable them to cultivate their minds sufficiently to acquit themselves honourably in much more advanced examinations,—coming so far short as to be plucked in an ordeal which every ordinary schoolboy might go through with ease. I would also ask, How many of the number have attended morning, noon, or evening classes?

In conclusion, I would advise my brethren in the large towns not to be so continually sending their darts at us poor country druggists, and at our manner of conducting the honourable profession in which we are engaged, but to look at home, to guard the flock over which they are placed; not only to provide food for their young, but to see to it that they eat and digest it with an earnestness of will beyond all doubt. By so doing, such calamities as the one in question will be averted. "SPES."

Barnsley, October 25th, 1871.

IMPROVED TINCTURE PRESS.

Sir,—My press is not quite understood; perhaps I am at fault for not explaining that the double power is obtained, not merely because it has two screws (for each has the double power to a limited extent), but because they convert the cross-beam into a lever in the second position. Your young readers will better comprehend it by this line A ———— C
B
(or *vide* any work on mechanics), the prop, or fulcrum A, being represented by the end of the cross-beam secured at rest by the nut; the weight B by the centre of the block, and the power C by the other end where the power is applied (these positions being reversed as each screw is used alternately); consequently as the line A C is + A B, so is power applied at C + what such power would be if applied direct at B, *i. e.* in this case double. I might have described the theoretical power of each screw as doubled by the leverage of the cross-beam; the result would have been the same, but as two screws must be used, I thought it simpler to describe it as so much for each. Now we will suppose *two* persons employed in screwing my press, as your correspondent suggests, what power would then be obtained? Exactly the same, not one additional pound, either theoretical or practical, as the two persons could but act as power and fulcrum to each other. I am surprised that so important a part of the principle as the leverage of the cross-beam should have escaped the notice of any one so well up in mechanics as your correspondent Mr. Brown appears to be, and equally so at his misunderstanding what I stated about the size of the screw affecting the power. Mr. Brown says, "no increase or diminution of the *circumference* of the screw will affect it;" granted, but I never used any such expression. I objected to the *bulk* of the screw generally, large screws being manufactured with a proportionately larger thread than small ones, although I see no reason why a fine thread should not be cut on a large bolt; but as they are not so manufactured, my objection is well founded. I should also wish to ask him if he has ever seen a sheet of block tin before it has been beaten into shape, which sometimes approaches a hemispherical form. To bear this its strength and substance must be something considerable; in my opinion, a small cylinder of it riveted, as I suggest, would be up to any pressure required in the retail laboratory, but would not bear what might be applied by such a press as mine. What that pressure really is I regret not being able to inform your correspondents, having no means of testing it; but theoretically it works out, as I have stated, to about three times as much as several of your correspondents agree in assigning to the press in general use. Allow me to remind your readers that my simple little press is not in a position to bear the severe tests to which some wish to subject it. As already stated, it was rudely constructed in the cheapest manner, merely as a pattern or working model, to experiment upon to discover the faults to be corrected in one of superior workmanship.

Now my press has only a pair of iron screws; the nuts were correctly made to my model, but unfortunately the smith only welded the spiked ends on instead of forging it from one piece, consequently both handles broke off from one of the nuts. The smith having emigrated, and no other in the neighbourhood having exactly the same pattern, I have had the nut imbedded in a wooden handle, and as one of the others seemed inclined to follow its example, I have been obliged to use the press very cautiously; even under these disadvantages it has met the requirements of my business, but it was hardly fair to subject it to this severe test.

A neighbouring chemist brought me a small cylinder containing the marc of forty ounces of tincture of orange-peel, from which he stated he had pressed off thirty-nine ounces, which I consider a very successful result by a single screw press, but he brought it to me to see if I could get any more out of it by my press. I transferred it to my cylinder, and even in the crippled state of my press soon produced a couple of drachms more, when the other handle, breaking off, compelled me to discontinue the experiment.

Several minor points of improvement suggest themselves for consideration before any of your readers attempt the construction of such a powerful press as I advised in my letter in the PHARM. JOURNAL, Oct. 21. For instance, the cylinder should be made of tolerably stout sheet-iron tinned, the female screw must be of great strength and beautifully cut. I should recommend a piece of one inch square iron bar, with a hole punched in the centre to receive a piece of steel to be welded in, and the screw thread cut in it. The ends must be hammered out, not welded on. Such a fine screw must be carefully preserved from injury by contact with the touch-plate. A flange filed (or rather turned) at the base of the nut, and fitting into the hole in the plate, would secure the screw from any contact with it. (If any of your readers fail to quite understand me, I will send them a model in cork or wood by post.) The top of the press block should be slightly convex, to ensure the pressure being in the centre, also to aid the leverage of the crossbeam, and some other points not affecting the general principle of the implement, the excellence of which I am sure the majority of your readers will approve. The superior method of applying the power so as to pull the screw instead of pushing it—discarding the cumbersome iron frame—great increase of power, moderate expense, etc., are all advantages too important to be overlooked.

I quite agree with the excellent suggestion of your correspondent to increase the depth of the cross-beam. I purposely sketched it slighter than the model, which I thought too thick, and intended planing down, to increase its elasticity, but I now think it unsafe to reduce its strength. Might I ask some of your readers with a better knowledge of mechanics than myself to favour me with their opinion on the proposed spring? It is quite imaginary, and would not directly increase the power, but it might enable it to be applied with greater ease, and by its automatic action diminish labour. Also to point out (not by taking exception to a term, but *bonâ fide*) any errors they may discover in what I have stated throughout this controversy, except the vexed question of power; as my calculations have all been expressed in the simplest terms, the errors will be easily detected.

October 30*th*, 1871. C. A. STAPLES.

Sir,—Will you kindly allow me a small space in the Journal to make a few remarks in favour of Mr. Staples' Tincture Press?

It is now several years since I left Mr. Staples' employ; and since that time I have occupied several situations both in the suburbs of London and in first-class provincial towns, and I have never met with a tincture press that so well answers the purpose of a retail druggist as the one described by Mr. Staples (PHARM. JOURN. September 9th).

One of the principal objections to other presses that I have used is, that they are too heavy and cumbersome; now Mr. Staples' press, on the other hand (as he mentions in his letter, PHARM. JOURN. October 14th), is portable and light. And, again, another improvement is the double screws, which enable one to so materially increase the pressure on the marc. I well remember (although it is so long ago since I used the double-handled press) how often I have taken out the residue after completing the expression, and noticed with surprise how perfectly every drop of spirit seemed to have been pressed out; so much so, indeed, that one would scarcely believe, on breaking up the dry residue, that it had ever contained foreign moisture in the shape of spirit.

I mention this simple fact, because it does apply to Mr. Staples' press, and it does not apply to other presses that I have used.

In conclusion, I would remark that if Mr. Umney had endeavoured to make a few practical suggestions for improving upon Mr. Staples' principle, instead of making it such a *sine quâ non* to prove the theoretical pressure, he would have more probably obtained the thanks of the trade in general.

W. WATTS, A.P.S. by Exam.

Campden, October 24*th*, 1871.

THE LIBRARY AND MUSEUM.

Sir,—Through the medium of your Journal, I beg to suggest what I think many, including myself, would find of great advantage, namely, the opening of the Library and Museum of the Pharmaceutical Society, say, for only two evenings a week, until 9 or 10 o'clock, instead of closing at 5 o'clock, as at present; thus giving many, who have one night a week for recreation, the benefit of that Institution. I hope this may not be overlooked.

16, *Cambridge Street*, A CHEMIST'S ASSISTANT.
Hyde Park Square, Oct. 18*th*, 1871.

EVANS AND SONS' MATERIA MEDICA CHEST.

Sir,—Will you allow me, through the medium of your columns, to thank Messrs. Evans and Sons, of Liverpool, for the five-guinea materia medica chest which they have presented to the Tyneside Chemists' Assistants' Association.

Much as may have been written with regard to the usefulness of this collection, too much can hardly be said in favour of it. It seems to me as complete as is possible, and the arrangement as perfect as so large a number of specimens in so small a comparative space will allow.

ALFRED BRADY, *Hon. Sec.*

29, *Mosley Street, Newcastle-on-Tyne, October* 21*st*, 1871.

"*Chemicus*" is thanked for his letter criticizing the doctrine of "skin tanning," but as we have already said, the discussion of this subject would be more appropriate in a medical journal.

W. S. Goyne.—The manufacture of acid chromate of potash is described in most chemical works.

B. Keene.—*Tamus communis.*

G. B.—We are unacquainted with the plant.

"*Peltatum.*"—The subject of your letter was fully discussed both in our columns and at the Council table of the Society for some years before and up to the time of the passing of the Pharmacy Act, 1868. It was then considered that, having due regard to the various interests affected, the titles mentioned in that and the first Pharmacy Act were the best that could be continued. We regard the question as having been settled. It would serve no good purpose to reopen it.

G. A.—The Secretary will communicate with Mr. Drewe on the subject of your communication.

"*Gelatine.*"—*J. C. K.* fully endorses Mr. Hustwick's remarks respecting the gelatinizing of tinct. kino. He has made large quantities without having found it to change, a result which he attributes to his having used the granular form or "gruffs" of the gum.

J. Bairnsfather (Kentucky) is thanked for the newspaper cutting forwarded by him. We think, however, that such a romantic story would be out of place in the PHARMACEUTICAL JOURNAL.

X. Y.—A student may enter the laboratory for a shorter period than a month, but the lowest fee is £2. 2*s*.

Dispensing Charges.—We have received a letter from "*A Youngster in the Trade, but a Lover of Fair Play,*" in which the writer expresses his indignation at the conduct of those who vend a six-ounce mixture for ninepence, or submit to dictation from their customers as to the price that should be charged. Lamentable as such conduct may be, we are afraid that the punishment for it which our correspondent proposes, that they should "be served as soldiers are when they desert or do anything very bad, viz. kicked out of the army and better men taken in their place, with better principle," is one that could not be carried out profitably in the present state of the English law.

W. S. N.—(1.) We think our correspondent was indiscreet in asking his customer the question. No pharmacist would make such a charge as he mentions. (2.) Having poured the tinctures into the bottle, let them completely moisten its sides, then mix and add the oils, and shake well; and lastly, add the cinnamon water, again shaking.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. J. Bush, Mr. J. T. Miller, "Juvenis," "Chemicus," "Quærens."

THE PRELIMINARY AND MINOR EXAMINATIONS.*

BY WILLIAM SOUTHALL.

As the studies of most of those now present have for their secondary, if not primary, object, the acquirement of sufficient knowledge to enable them to pass the examinations at Bloomsbury Square, and as I have the honour to be a member of the Board of Examiners, it was very natural that you should ask me to open the session by a paper on the subject. I have therefore hastily thrown together, as well as time would permit, a few practical hints that may be useful in your work of preparation.

Let me impress upon you that the object of the examination is not to force you to cram your heads with ill-digested knowledge that may or may not be ready when wanted, and will be pretty certain to evaporate quickly after the examination is over, but it is intended to ascertain if you are sufficiently informed on certain subjects to be qualified to perform certain duties. It is obvious that the great aim of study is to gain knowledge, which is power; the examination is a means to this end, not the end itself. One man may have an excellent memory, and trust to it too much, not taking the trouble to understand what he learns, and consequently his store will be of but little use to him; whilst another who has carefully sought out the bearings of his progress, although he may not have got through quite so much, will have obtained a mastery of his subject that will stand him in good service, not only at the examination-table, but for the purposes of his profession.

With the exception of Latin, the standard of knowledge required for the Preliminary Examination is one that ought to be possessed by every boy of the middle class before he leaves school; and, as regards Latin, it is now well known that a knowledge of it is required by those who enter the business, and, therefore, it becomes a parent's duty to see that his son has the opportunity of learning it. The education given at the British School here, is amply sufficient for the requirements of the examination in English grammar, composition and arithmetic, but then there is no Latin. At many of the grammar schools Latin is taught to the prejudice of English; whilst many of the private schools have the reputation of giving but a poor education. I suppose that each of these causes contributes to swell the hitherto large number of failures to pass, which must be annoying both to parents and pupils. The kindest and most judicious plan would be, for every druggist when he takes an apprentice, to require that he should first pass the Preliminary, as he would do so better when fresh from school; of course there are many cases in which this would not be practicable, but, as a general rule, the earlier the education of a boy is directed to the course he is likely to follow in life, the better it is for him. With regard to older men who have not had an early education in Latin, they will find it more advantageous to turn their attention to the two pharmaceutical books than to Cæsar, as much of the phraseology in these must be already familiar to them, and the number of Latin words in them is much less than in the latter; but whether they study Cæsar or not, they should attend the Latin classes now open to them.

We now come to the Minor Examination. The first subject in the list to be found in the printed regulations, is Prescriptions—reading prescriptions. If the student is engaged in a dispensing business, he has already in the course of his duties to translate prescriptions daily, but his knowledge requires extension. There are printed books, such as 'Selecta e Præscriptis' to study; there are also, in many large towns, volumes of autograph prescriptions which may be referred to, and these are especially useful. The Society owes to Mr. Ince's labours a splendid collection of such; and it is our own fault, as chemists of Birmingham, that hitherto we have had no portion of it, as until lately nothing has been done here to aid pharmaceutical education. Such being the case, I am glad to hear that steps are being taken by some of our younger members to make a collection, but in the meantime the volumes of copies which exist in most businesses of any standing are not to be despised. The collection of prescriptions in London is, I believe, available to students under certain regulations. As far as I have seen the prescriptions to be found in the examiners' volumes, those written by English physicians are not at all more difficult than the average generally met with in business; but when an examiner is told the same day that *undecimam* means nine, ten and eleven (or eleventh), or a candidate does not know what *urgente dolore* means, or says that the last word means solemn or dolorous, it is obvious that his knowledge of Latin is rather deficient. The man, too, who says that *manus* means body, or *sternum*, stern, would find still more difficulty in coming to a right conclusion as to the part of the body intended, if he met with "*Hypochondrio dextro*" in the prescriptions of a well-known Birmingham physician. A candidate may say when he meets with an unusual word, that if at home he would look for it in a dictionary, which is a reasonable remark; but dictionaries often give two or three meanings, and it requires some insight to choose the right one,—as in case of a mixture ordered to be taken, *spiritûs difficultate*,—and this can only be acquired by study or practice; moreover, words much abbreviated are hard to find. This brings us to the task of reading abbreviated words in full. To an assistant in good practice this is often more difficult than translating, unless he has a good knowledge of Latin, as most physicians abbreviate their words more or less, and thus he seldom sees them in their proper form. I would recommend the student to make a practice of writing out a prescription or two in full every day, taking advice from a pharmaceutical Latin grammar or other guide to begin with, when he will soon get into the right way, and the practice once gained will be easily followed. A little book, called Britten's 'Dispenser's Vademecum,' is a useful compendium of pharmaceutical Latin, and is arranged alphabetically. Practical Dispensing comes next on the list—to weigh, measure and compound medicines.

Misce S. A. was once a much more common affix to a prescription than it has become of late, but the art is, or ought to be, none the less understood. Nothing but practice and good instruction will make a good dispenser, but surely the importance of the office is worth the pains. Let us examine a few points in which a right or a wrong mode of procedure is evidenced. Firstly, in weighing. One man picks up his scales as if they burned his fingers, and they wobble about (excuse the word) in a most perplexing

* Read at a meeting of the Midland Counties Chemists' Association, Oct. 26th, 1871.

manner. I have often shown a young man the proper way of holding them, but this you will see is not an examiner's business, and ought to have been explained by some kind soul long before. Or, perhaps, another may have a piece of elastic paper on the counter under one of the scale pans, and wonder that the balance rises first high then low without any change of weight in either scale. Again, one holds his measure so that requiring half an ounce, he gets either three drachms or five, according as it is tilted backwards or forwards. So in making pills, one man will triturate in a mortar with care and precision all the ingredients, putting in first those that require most care in division, whilst another will throw them all into a mortar together, just as they come, coarse and fine; whilst as an extreme case, I may mention that I have seen a man satisfy himself with cracking crystals of sulphate of copper by means of a spatula until they were a little less than pins' heads, and then mixing and dividing them into 12 pills, all on a slab. The same with mixtures: if all the articles are hurried into a bottle "anyhow," the result is often most unsatisfactory, some mixtures having a totally different appearance if the order of mixing is transposed—to say nothing of powders that agglomerate. Then again, fractional parts of a grain puzzle some dispensers very much, but this will hardly be the case when the Preliminary has had its full effect; and that it is necessary to understand fractions, the prescription below that was dispensed a few days back, shows plainly.* The instructor of apprentices is often to blame for the way in which his pupils dispense. This will show itself in their weighing out a white powder on a dirty prescription, instead of using a clean paper, or in their using a two-drachm box to hold a dozen pills, or other manifestation of a niggardly economy that defeats itself, as more time is wasted in writing the label, for which there is not room, than would pay for a larger-sized box. Again, some are apparently taught to divide powders with a spatula, at which a few show considerable skill, but supposing the wrong quantity of any article be taken, what is to check the error, as they have not always an examiner overlooking them. A patient would probably be surprised, if one day he received a box of pills, and a few days afterwards one of powders from the same prescription, two powders for a dose, and yet this is an error that, unaccountably to me, I have so frequently noticed that I mention it; indeed, I have seen blue pill carefully rubbed to as near a powder as possible, and divided into papers, the prescription in the case being perfectly plain to read.

The prescriptions in use for dispensing at Bloomsbury Square are of necessity comparatively simple and easily dispensed, so that a fairly good dispenser has no need to be nervous; but if he be, it is easy to judge between nervousness and incapacity. I have alluded to the translation of directions for use, in my remarks on reading prescriptions, but in addition to those, it is well to observe that a label should be in elegant English as well as being a correct translation, as if it is so expressed that it can scarcely be understood it is but little better than if incorrect, as for example, "two pills to be taken every four hours, three times;" instead of "for three doses," and so on.

* Ext. belladonnæ gr. $\frac{1}{6}$, ext. stramonii gr. $\frac{1}{5}$, ext. cannabis ind. gr. $\frac{1}{3}$, ext. opii gr. $\frac{1}{2}$, ext. hyoscyami gr. $\frac{2}{3}$, ext. aconiti gr. $\frac{1}{3}$, ext. conii gr. j, P. glycyrrh. q. s.: ft. pil. mitte vj.

I have dwelt at some length on practical dispensing, on which, indeed, much more might be said, but it becomes the province of the teacher to give minute directions. These few general hints, however, may be useful to some; and in conclusion I would remark how essential are care and neatness, as some men scatter and throw about, in making pills and powders especially, almost as much as they use.

Next comes Pharmacy. This refers to the knowledge of what we term pharmaceutical preparations as distinct from chemical: firstly, as to ability to recognize them when seen and handled; secondly, as to knowledge of their composition and preparation. This latter knowledge can only be obtained practically by making them or by study of the British Pharmacopœia. It is most important that every pharmacist should know what he is using. If a customer comes in and asks him what compound rhubarb pill or compound tincture of cardamoms contains, or wants to know what confection of senna is made of, he ought to be able to give a correct answer. Likewise, if a surgeon asks how much ext. cannab. ind. is contained in a drachm of the tincture, it looks well not to have to consult the Pharmacopœia. He also should be able to recognize tinct. valer. and tinct. lupuli respectively, but for fear he might not succeed it would be well beforehand for him to put specimens of these and other preparations, tinctures especially, into ounce bottles and get some one to number them, keeping a key to the numbers; and thus he would exercise his nose—a most useful organ to a pharmacist—in detecting differences of odour, and his eyes in distinguishing shades of colour. It is well, however, that he should get good test samples, as bad ones would only serve to embarrass him. Squire's 'Companion' is a useful book in describing the appearance of preparations, and also in stating their strengths and doses.

Materia Medica.—Here again study from the articles themselves is required. The directions in the regulations are so clear that I cannot add much. It is important to have a good work on materia medica. Pereira is expensive but excellent; Royle and also Garrod are cheaper and are very useful books. For the student in the country or in a small business, where preparations are procured from the wholesale druggist, it is necessary that the student should take further steps to acquire a better acquaintance with the articles of the materia medica than the contents of the shop afford him. This may be obtained wherever there is a museum or from one of the collections of materia medica specimens that are to be purchased, with which many local societies are furnished, and they also give useful information in connection; but it is absolutely necessary that the student should, by some means, obtain access to specimens.

Botany.—I have given my views more at length on the study of botany in the PHARMACEUTICAL JOURNAL; but I would repeat, that it is far the best plan to commence with some elementary work, taking, at the same time, living plants themselves, common ones will do, and examining them in connection with your reading, getting the aid of a good pocket lens. Such a book as Oliver's 'Elementary Botany' leads the way in a most instructive and interesting manner to some knowledge of the structure, external organs and physiology of plants; and then, when his interest is awakened, the student will turn to 'Bentley' as a text book to perfect his necessary knowledge of details with much more pleasure than would otherwise have probably been the case. A mere book knowledge of botany partakes too much of the nature of a cram; and it is easy to tell whether a student has studied from nature or not. A student will learn (out of a book) the names of the different varieties of leaves; but if he is shown a lanceolate leaf he will probably say it is ovate, and other things in the same way, unless he has also studied from nature. It is to be hoped that next year the indigenous medical plants, and some others that are easily cultivated, will be grown at the Botanical Gardens, and that students will have liberty to go there, as such opportunities for study are very important, and will prevent the sad confusion that too often exists in the student's mind respecting the identity of English medicinal plants.

Next and last comes the great subject of Chemistry. We take our popular name of Chemists from our supposed acquaintance with this science; but chemistry has developed so wonderfully of late years, that it is but a very limited branch of its professors that pharmaceutical chemists represent. Still we ought to have a moderate knowledge both of theoretical and of practical chemistry, and many excellent chemists have sprung from our ranks. When young hopeful is brought by his father to the druggist, the latter is informed that the young gentleman has evidenced, by his fondness for experiments, his fitness for the profession; and it is to give this energy scope that he is placed behind the counter. Alas! it too often happens that the man of drugs looks blandly on his expectant pupil, but gives him little time to pursue his researches; or the latter, when he has time and opportunity afforded him, satisfies himself with burning his fingers and clothes, or making explosions and stinks. Now, however, that the examinations are compulsory, there is a great awakening to the necessity of early study; and to this the number of students who have entered their names for our lectures testifies. There is no royal road to chemistry; the turn for experiments is the first round of the chemical ladder, and the secret of the ascent is by perseverance and patient study, under proper guidance, to keep still getting higher. Let your motto be "Per aspera ad ardua tendo." Lectures on chemistry, as well as on botany, are of the greatest assistance, and should be attended if possible. An attendance at the working classes on chemistry is also a great help to those who have the opportunity. The regulations explain clearly the outline of the examination, so that I need not dilate upon it. Dr. Attfield's work on chemistry is most useful to pharmaceutical students, but it is well to take two works on the subject, as the student has then the benefit of different minds, and it is also well that the pharmaceutical bias should not be too strong.

I have now given a running commentary on the published regulations of the Board of Examiners, and, in conclusion, would remark that the use of the best books available on the different subjects is most advantageous to the student. To one who has studied observantly, a short synopsis is useful for occasional reference, but to any one who uses it as a "cram," it is apt to prove a delusion and a snare. There are few of us but forget much of what we learn; we are much less likely to do so, if we study thoroughly as far as we go. I have heard it said by or of such-and-such a student, that he answered almost every question, and was surprised that he had failed; and so probably he did, but his answers were perhaps almost all wrong. I think such men must have tried the ready method of cram, and experienced, to their cost, that it was a failure, as one who has really studied is generally more cautious in his answers, and has his understanding to guide him as well as his memory. I have taken the liberty to allude to some mistakes that candidates have made, but have no recollection who made them; indeed, the identity of the candidates is generally unknown to the examiners. The most painful part of an examination day, both to examiners and examined, is to hear of the failures, whilst the pleasantest to the examiners is the signing of a good crop of certificates. Examiners and examined have always been, and, I suppose, always will be considered to be natural enemies, so I will enliven the end of my paper by giving you a grotesque picture of his tormentors, written by a student who afterwards rose to high eminence in the field of scientific natural history, the late Edward Forbes.

"I followed him instinctively, and saw
A sight which sickens me to recollect.
There, in a lofty and a lengthy hall,
Around a table covered with green baize,
Sat the Examinators,—animals
Of wondrous shapes, with horns and bills, and claws
And hoofs, and asses' ears and grinding teeth
Wherewith to torment and to terrify
The luckless student who, unknowing what
A horrid fate awaited him, came there
In Sunday clothes to seek for a degree."

VESICATING INSECTS.

BY M. C. COOKE, M.A.

(Continued from page 322.)

Violet Blister Fly, *Lytta violacea*, Br. and Ratz.—Brandt and Ratzeb. ii. t. xviii. f. 10. *Lytta gigas mas*, Buchn. Repert. xxvi. t. i. f. 6.

Found in Central India.

This species is described by Brandt and Ratzeburg as follows:—

"Lytta violacea.—Head rather large, strongly rotundate-quadrate, the posterior margin nearly straight above, the lateral margins arcuate, blackish-violet, finely and somewhat uniformly punctate, shining; forehead very slightly convex; crown convex in the middle above the forehead, and above the crown a fine longitudinal impression. Antennæ filiform at the tip, nearly smooth; the first joint clavate, moderately swollen at the apex; the second joint nearly orbicular, about one-third the length of the first; the third joint cylindrical, longer than the first. The thorax above elongate-quadrate, gradually narrowed in front, and with the reflexed portion shining, smooth, with scattered impressed points; in the middle with a small furrow which unites with a triangular impression in front of the posterior margin; lateral margins slightly prominent. Scutellum triangular, very small. Breast with fine scattered black hairs arising from punctate impressions, otherwise smooth, shining, uniform blackish-violet. Legs moderate, violet, with fine black hairs. Elytra widened behind, dull blackish-violet, very finely granulate-punctate, and clothed with depressed, under a lens very conspicuous, hairs, posteriorly somewhat widened. Length 6–8‴. Breadth 2½‴."

According to the Pharmacopœia of India, this is one of the species employed there as a vesicant. It is also cited by Pereira.

Blue Blister Fly, *Lytta cærulea*, Leuckart.—Geiger's Mag. Pharm. xi. 2. 1825, p. 132.

Inhabits Bengal.

We have been unsuccessful in all attempts to meet with the portion of the magazine which contains the description of this insect in any London library. The British Museum collection does not contain any specimen referred to this name. According to Leuckart, it is a pharmaceutical species.

Large Blister Fly, *Lytta gigas*, Fabr.; dark violet-blue; breast reddish-brown.—Fabr. Sys. ii. p. 77; Brandt and Ratzeb. ii. t. xviii. f. 14, 15. *Cantharis gigas*, Oliv. Ent. iii. t. 1. f. 9. *a. b. c.*

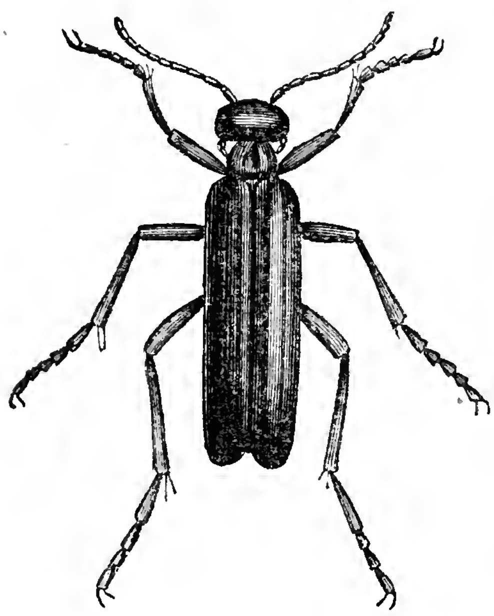

Fig. 7.—*Lytta gigas.*

Double the size of *C. vesicatoria*. Antennæ filiform, bluish-black. Body of a greenish-blue beneath, with violet reflections. Head large and inclined. Thorax attenuated anteriorly. Elytra minutely punctulate, with three elevated lines. Upper surface of the body of a bluish-black, with a large reddish-brown spot on the breast. Feet long and black.

Native of Senegal, on different plants.

According to the Pharmacopœia of India, it is found also in Central India. It is included in Pereira's 'Materia Medica' as a vesicant in use.

Sumatra Blister Fly, *Lytta ruficeps*, Illig.; black; head rufous; antennæ black; elytra obtusely acuminate.—Illig. in Wiedem. Arch. i. p. 140; Brandt and Ratzeb. ii. t. xviii. f. 7; Waterh. Trans. Ent. Soc. 1871, p. 405.

Inhabits Sumatra and Java.

Totally black, except the head, which is reddish-yellow. The clypeus is yellowish, with a transverse black band. The labrum has a notch in the front margin which is yellowish; the other parts of the mouth are more or less fuscous. The head is polished, sparingly but distinctly punctured. The thorax is subquadrate, slightly broader in front than behind, abruptly contracted and rounded in front; the fore part is slightly impressed on each side, the whole surface is thickly and distinctly punctured; the disk has a lightly-impressed longitudinal line, which runs into a deep fovea at the posterior margin. The elytra are parallel, not narrower at the base than at the apex, where they diverge, and are each rounded. The antennæ are four-fifths the length of the elytra, filiform; the second joint two-thirds the length of the first, the third a little longer than the first, the fourth two-thirds the length of the third; the remaining joints gradually increasing in length, and tapering. Legs simple. Tarsi beneath spongy, fuscous. The metasternum and abdomen clothed with short grey-black pubescence.

The male is rather more slender than the female. The antennæ are longer (very nearly as long as the elytra), the second to eighth joints furnished with long hair on the lower (or inner) side; the anterior tibiæ are furnished with long black hairs; the inner side of the femora and tibiæ clothed with golden pubescence. Length 6½–10½ lines.

Good specimens of this insect appear, in some lights, to have a reddish-brown pubescence, but a slight alteration of the position makes it appear greyish.—*C. O. W.*

This insect is stated, on the authority of Brandt and Ratzeburg, and others, to be employed as a vesicant in Asiatic countries.

(*To be continued.*)

PREPARATION OF DILUTED PHOSPHORIC ACID.

BY E. B. SHUTTLEWORTH.

The officinal process of the British Pharmacopœia for diluted phosphoric acid is a troublesome and dangerous one. The use of closed glass vessels, when operating on an explosive substance like phosphorus, is attended with considerable risk, not only to the apparatus, but the person and property of the operator. The apparatus is unnecessarily complicated, involving the employment of a retort and Liebig's condenser, while the advantage gained on the score of economy of acid is so trivial as to be practically unworthy of consideration.

A much better process is that of the United States Pharmacopœia. In this the diluted nitric acid is placed in a porcelain capsule; the phosphorus is added, and the whole covered by an inverted glass funnel of such dimensions that its rim rests on the inside of the capsule, near the surface of the liquid. A gentle heat is applied, and, if necessary, the action moderated by the addition of a little distilled water, which can be readily applied without in any way disturbing the operation. After the phosphorus has disappeared, the funnel is removed, and the concentration of the acid is effected in the same vessel by a further application of heat.

As far as the apparatus is concerned, it will readily be seen that the latter process is much more simple; the danger of explosion and fracture is almost impossible; most of the nitric acid is condensed, and trickles down the funnel into the capsule, while the manipulation is easier, and the operation can be carried to completion in the vessel in which it was commenced.

In both processes, however, the nitric acid is used in a very dilute form. According to the experience of the writer, this occasions a waste of time, and is attended with no advantage. The action of the dilute acid on the phosphorus is very feeble, and, in operating on larger quantities,—say ten pounds of phosphorus,—eight or ten days are required for the solution. The acid need not be weaker than that of sp. gr. 1·24. At this strength there is no danger of explosion, or a too rapid action. After many and cautious trials, he has now no hesitation in operating on the above-named quantity of phosphorus, with a carboy of acid of the strength named; and by so doing the solution may be effected in from fifteen to twenty hours. Nothing at all approaching to an explosion has ever occurred, but the precaution is always taken to have a quantity of distilled water near at hand, so that it can be at once added if, by the concentration of the acid, the action becomes at all violent.

In driving off the excess of nitric acid, after the phosphorus has been dissolved, a considerable degree of heat will be required, and the greatest care should be taken that the acid has become quite cool before adding the water for dilution. If this is neglected, and the water is added to the hot acid, an explosion is inevitable, owing to the rapid change of the water into the gaseous form. Indeed, it would be much less dangerous to pour water into a ladleful of melted lead.

For this, as well as all other operations in which solutions of acid or alkali are employed, the use of enamelled iron vessels must be avoided; nothing but porcelain, or at least Wedgwood, should be used. In this connection, the writer would protest against the use of enamelled vessels for any of the purposes of pharmacy in which an acid or alkali-proof material is required. He has never yet met with a vessel of this kind that was at all reliable, being either of a material readily acted on, or pierced with minute holes, exposing the underlying iron, and consequently contaminating everything with that metal. —*Canadian Pharm. Journ., August*, 1871.

THE PRINCIPLES OF GAS ILLUMINATION.

(*Continued from page* 326.)

The draught, or in-flow of air upon a flame of a given size depends greatly upon *the velocity with which the gas issues from the burner*. With argands there is a special means of regulating the air-supply (viz. the chimney); but with all burners, whether argands or naked burners, the velocity with which the gas issues has an important influence upon the air-supply; and in the case of naked burners (batwings and fishtails) this velocity of issue is, speaking roundly, the *sole* regulator of the air-supply.

Every flame, by its heat, produces an upward current which draws in upon its sides the surrounding air; but (the heat of the flame remaining the same) the greater the ascending velocity of the gas the greater is the draught made by the flame, and the more air is drawn in upon it. A gas-flame rises into the air like a rapid stream entering or passing through a quiescent pool,—producing eddies, setting in motion and drawing in upon its side, in currents, the surrounding water. The more rapid the entering stream the greater the currents and eddies, the watery draughts, so to speak, which it makes in the pool; and these inflowing currents not only play upon the sides, but tend to mingle with the stream itself. Thus there are two constant and unavoidable causes of draught or air-supply to a gas-flame. Firstly, the ascending power or velocity of issue which gas possesses, even when unignited, owing to its being lighter than the air; secondly, and chiefly, the fact that it is a *flame*, a source of heat, producing a partial vacuum which the surrounding air flows in to fill up.

But with the gas-flame there is a special source of disturbance, and that is the pressure under which it issues from the burner. The increased velocity thus given to the gas augments the draught upon the flame to an extent that is not counterbalanced by the quantity of gas consumed, the discharge of gas from the burner increasing only in the ratio of the square root of the pressure. In this way the gas-flame is brought into contact with more air than it is able to bear without loss of illuminating power. Other points to be observed are that the supply of gas to all parts of the flame should be equal, and in an even and steady current, without any twist.

The investigation as to the effect of the air-supply on the illuminating power yielded some interesting results. The size or height of gas-flames is notably diminished by increasing the draught or air supply. With an argand burner this draught can be regulated by means of the chimney, and the apertures at the bottom of the burner. Take Sugg's London Argand No. 1, consuming five feet an hour of sixteen-candle gas. Without the chimney, we get a waving yellow flame about eight inches in height, and ocasionally smoking. The gas, in fact, extends itself upwards until, by the size of the flame, it comes in contact with the air to the requisite extent to produce entire, or almost entire, combustion. Put on a chimney, of the most suitable kind for this quantity and quality of gas, and the height of the flame is at once *reduced by one-half*, nevertheless the illuminating power of the flame is *increased by one-half!* If, as is held by some, a slow rate of combustion were the best means of developing the illuminating power of gas, the tall flame which rises from an argand without the chimney ought to give the maximum of light. But the fact is otherwise; for, when the chimney is placed on the burner, and the combustion of the gas proceeds much more rapidly than before, the illuminating power of the flame is largely increased. The explanation of this evidently is, that the brilliancy of the flame, owing to the intensity of the combustion, is so much increased as to far more than compensate the diminution in the size of the flame. Instead of a tall dull yellow flame about eight inches in height, we have a flame less than four inches high of brilliant white, which gives much more light. The cause of the shortening of the flame is the more rapid combustion of the gas, owing to the increased draught or air-supply produced by the use of the chimney. Hence it is manifest that rapidity of combustion, so far from occasioning a loss of light, may—and in this case does—greatly increase the illuminating power of burning gas. But if we still further increase the draught by using taller chimneys, we obtain opposite results; a further diminution occurs in the size of the flame, which is not compensated by the increase of its brilliancy. The explanation of these opposite results throws an important light upon the real cause of the startling diversity of illuminating power obtained from gas when consumed in different burners and under different conditions.

As is well known, the Bunsen burner, in which air is made to mingle with the gas before the point of ignition, gives a pale blue or violet flame which is almost lightless. But in proportion as the mingling of the air with the gas is diminished, by closing some of the holes in the stem of the burner, the flame becomes white and light-giving. A commingling of air with gas enormously diminishes, and may entirely destroy, the light-giving power of gas. But in what manner is this effect produced?

First, take the case of a Bunsen burner. The air which mingles with the gas before the point of ignition, and which (so to speak) is burnt along with it, contains 73 per cent. of nitrogen, which is a non-luminous, indeed, incombustible body; and the result is, that the gas-flame being diluted with this incombustible body, cannot possibly attain the temperature which it would possess if burnt by itself,—part of the heat of the burning gas being taken away in heating the intermingled nitrogen. But oxygen when in excess plays a similar part; for that portion of the oxygen of the air which is not needed to produce the combustion of the gas cannot burn, and simply dilutes the gas with a non-luminous body, which abstracts a portion of the heat generated by the burning gas. Hence, the flame of a Bunsen burner is, or may be, diluted by two non-luminous bodies—namely, by the whole of the nitrogen of the air admitted into the stem of the burner, and also by that portion of the oxygen of the air which is not needed to produce combustion of the gas, yet which, under the influence of "pressure" and draught, may commingle with the flame, not only of the Bunsen, but of every kind of burner. The consequence is, that the two non-luminous (and in this case incombustible) diluents—the nitrogen and the excess of oxygen—mingling in the flame, are heated by abstracting heat from the burning gas; so that it seems obvious that the gas-flame cannot acquire the high temperature which it would otherwise possess.

The flame of the Bunsen burner has hitherto been regarded as the hottest of all gas-flames. But this, the referees say, is not correct: for, in repeated experiments, a platinum wire has melted in the blue part of batwing and fishtail flames, whereas the same wire did not melt in any part of the Bunsen flame. The special advantage of the Bunsen burner is that it gives a smokeless flame, and also that, by the intermixture of air, the gas is consumed within the smallest possible space; and *cæteris paribus*, the smaller the flame in which a given quantity of gas is consumed, the hotter will be the flame, more gas being burnt in the same space. At the same time, as already said, it seems obvious that owing to the intermixture of air with the gas, the flame of the Bunsen burner cannot possess as high a temperature as would be the case if an equal quantity of gas could be burnt pure in an equally small flame. The Bunsen burner consumes the gas in the smallest possible space, thereby concentrating the heat developed by the burning gas; but, on the other hand, the intermixture of air appears in some respects to alter unfavourably the conditions of combustion.

In all flames like those of gas, of a candle, or a match of wood or paper, a portion of the flame is blue. And this blue portion is always at the bottom of the flame. Any one who examines a burning candle will also observe that there is a peculiar band of very bright blue forming the outermost rim of this lower part of the flame. And if a burning spill of wood or a paper-match be examined, it will be seen that this bright-blue part of the flame is strongest (not only at the bottom but also) at the point nearest to the unignited part of the match; *i. e.* at the point where the substance first takes fire. Doubtless the blue and almost lightless part of all flames is produced from the combustion of hydrogen (which ignites more quickly than the carbon), and the bright-blue rim edging this under part of the flame is due to carbonic oxide. By repeated experiments, also, it was found that the blue part contains within it the hottest point of the flame.

The upper white portion of gas-flames may be said, speaking roundly, to be the only portion of the flame which gives light. How is it composed? The fact of gas-flames smoking shows that some portion of gas may pass through the whole of the flame without being perfectly consumed; and the upper portion of the flame manifestly consists of gaseous atoms which have passed through the lower blue portion of the flame unignited, or else which acquire an increased temperature as they ascend. As the illuminating power of gas is due to the incandescence of carbon, it appears evident that, while the free hydrogen burns in the under part of the flame, the hydrocarbons burn chiefly in the upper part: and the intensity of their combustion is aided by the great heat generated by what may be called the furnace of hydrogen below.

There is a striking difference of appearance between gas-flames and what may be called *natural* flames; *e. g.* of burning coal or of a candle. The latter flames are more solid,—they have less blue and more white than gas-flames. This is owing, in the first place, to there being more carbon in these natural flames than in gas. Take the case of a candle, or of the flames from coal burning in a grate. In both of these cases the whole of the light-giving vapours are consumed in the flame; whereas in gas, a large portion of the light-giving vapours of coal are lost, being withdrawn by the condensing apparatus in the gas-works. It is only the *permanent* vapours of coal that constitute gas,—*i. e.*, one which does not condense under ordinary circumstances. But a large proportion of the illuminating elements of burning substances condense readily, and therefore cannot be used as gas. In an oil-lamp or a candle, the *whole* of the illuminating vapours of the oil and the tallow go to form the flame; but in gas a large portion of the illuminating constituents of the coal is withdrawn by condensation in the form of tar, naphtha, etc.; for, as these vapours condense at the ordinary temperature of the air, they would, if left in the gas, become solids as soon as they cooled, and thereby choke the pipes. This is one cause of the difference between natural flames and gas-flames: the former are produced by the whole illuminating vapours of the burning substances, whereas in gas all the non-permanent vapours are withdrawn, and the light is due only to the permanent vapours yielded by the coal.

The effect of the temperature of gas on its illuminating power, and how it affects the development of that illuminating power in burners, is a question that has been little investigated; but, in the main, it has been held that the warmer the gas supplied to the burner, the greater will be the amount of light obtained compared to the quantity of gas consumed. Some experiments on this subject were made last year, in the laboratory of the University of Munich, in which the burner was attached to a U-tube, immersed alternately in a freezing mixture and in a liquid at a high temperature.

(*To be continued.*)

NITRITE OF AMYL.

Some time since, we gave an abstract of a paper from the *Medical Times and Gazette* which contains some particulars as to the therapeutic uses of the new remedy, nitrite of amyl.* In the *Practitioner* for October, Dr. Talfourd Jones, Physician to the Brecknock County and Borough General Infirmary, furnishes some other interesting information concerning its mode of application and its effect in some cases in which he has used it with considerable success.

Dr. Jones states that he has now given it experimentally to some fifty friends and patients, and he has found that its inhalation invariably causes increased frequency of the cardiac pulsation, accompanied by flushing of the face, warmth of head, face and neck, and perspiration—the warmth and perspiration often being general. A pulse of twenty in the quarter-minute will often rise in ten or fifteen seconds to forty. It sometimes causes a little breathlessness, or now and then giddiness, and in some a feeling of intoxication.

It may be administered by inhalation, by the mouth or by subcutaneous injection. Dr. Jones considers the best and safest way to be by inhalation. He usually pours five drops upon a piece of lint the size of a crown-piece or larger, and holds it close to the nostrils for ten or twenty seconds, or until an acceleration of the pulse is felt or the face begins to redden. Another plan is to drop the nitrite on to a pocket-handkerchief, and then hold it to the nose just like chloroform, or it may be inhaled directly from the bottle. He has never seen any bad effect result from its use, but he considers it to be an important point that it should be administered with great judgment and caution to aged persons or those who are the subjects of arterial degeneration.

Dr. Jones considers that it acts by relaxing muscular spasm, and he mentions several cases of spasmodic asthma, angina pectoris, colic, etc., in which it gave immediate relief. In the case of a young man suffering from an-

* Pharm. Journ. 3rd Ser. Vol. I. p. 209.

gina pectoris, it is stated that the patient carries the drug about with him and smells directly from the bottle whenever he feels an attack coming on. Since the 26th of last January this person has used more than thirty ounces of the nitrite, for which large quantity he accounts in the following way. He pours about half a teaspoonful into a small stoppered bottle, which he constantly keeps in his pocket. After he has used it for one or two attacks he finds that it gets "flat," and fails to produce such good results as fresh amyl; so he throws it away and replenishes from his stock bottle. This result is corroborated by Dr. Jones.

THE PREPARATION AND PROPERTIES OF THE VARIOUS KINDS OF CHINESE TEAS.

BY F. PORTER SMITH, M.B. LOND.

It is proposed to review the various stages and processes of growth and manufacture of tea, as supplied by China to the civilized world, with reference to the medicinal and dietetic properties of the various forms of this "necessary of life." It is to the credit of the Celestials that, whilst they do not live under the strict rule of Islam, they have elected to confine themselves chiefly to the use of a drink which has commended itself to all sorts and conditions of men. In no other country is such a store of wealth drawn from the very leaves of trees as in China, where the mulberry-leaf furnishes silk for clothing, and the tea-leaf material for satisfying hunger and thirst.

The tea-plant of China, the *Thea Cantoniensis* or *Thea viridis* of botanists, is not the same as that used in very remote periods by the people of the classical period. They probably used the leaf of the chicory, as well as those of other plants still used in various parts of the country, such as the willow, the holly, the *Sageretia theezans*, and other plants.

Since the seventh century of the Christian era the growth of the tea-shrub has been sufficiently extensive to invite taxation by the Emperor, though to a much less extent than cereal crops, the chief dependence of the people of the "Middle Kingdom," the name by which China is known to its own people. The tea-shrub is met with in Hupeh province as a small, stunted evergreen bush, varying from one to three feet in height, and covered with a precarious growth of young shoots, bearing shining, ovate-pointed and irregularly serrated leaves. It is grown on the hill-sides or terraces of such districts as have a red and rapidly disintegrating sandstone soil, where rice could not well be raised, from the difficulty of irrigation. The shrubs are renewed from young seedlings, after some ten years or so, according to the enterprise of the peasant grower. Formerly the bushes were renewed every five years, but the extraordinary and insatiable demand for tea has led to the exhaustion of the plants, as anything in the shape of tea is bought by the speculative and indiscreet foreign trader. The seeds are often abortive, from the damage done to the tree by the remorseless stripping of the leaves. The seeds require some peculiar treatment, such as the soaking in a prepared liquid, or in an artificial mould made of exhausted oilcake. Several seeds are placed together to ensure the growth of a single seedling. The seeds yield a fixed oil, which is said to never turn rancid. The tea oil known to foreign residents in China is the product of the seeds of the *Camellia oleifera*, a plant called by the same name (*Ch'a*) as the tea-shrub. The various kinds of tea—namely, green, black, red, and brick tea—are all produced by the same kind of shrub, which shows some slight tendency to variation in some such simple characteristics as the length of the leaf, etc. The leaves are picked at three or four periods of the year, commencing with the latter part of April. The bushes are finally clipped to make some of the brick tea, and to encourage the growth of young shoots in the coming spring. The raw leaves are dried in the sun by spreading on mats, and the shrivelled product pressed and rolled by men, who stand in tubs, kneading the leaves into a ball with their naked feet. This operation gives the twist to the leaf, and removes superfluous watery juices. The tea is seldom dried by fire by the small tea-growers, unless the weather be wet and the tea liable to mould from the want of sunheat. It is stored in bags long enough to collect a quantity, and is then "fired" by placing it in thinnish layers on the convex diaphragm of a large hopper or basket, shaped like a dice-box, with both ends open, which is put over a charcoal fire. The leaf is exposed to this heat (which never exceeds 212°, and is moderated by placing a thick layer of wood ashes over the fire) for about two hours, being stirred up several times, so as to heat the whole of it gradually and thoroughly. Processes of sifting, winnowing, mixing, and picking follow, and a final "firing," to get rid of moisture acquired during the manufacture, fits it for packing in chests. The stalks are usually rejected, as foreign tea-buyers do not like them. They contain all the properties of the leaf, and are largely consumed by the Chinese. The tea ought to undergo no change in the chests, which are carefully closed by soldering. The flowers of the *Aglaia odorata*, the *Jasminum Sambac*, the *Chloranthus*, and perhaps other plants, such as the *Gardenia*, are used to scent the tea. Dried leaves of the *Salix alba* are used to adulterate tea sometimes, but in the interior of the country such practices are commendably rare. Black tea forms the bulk of the produce, and is preferred by the Chinese for ordinary drinking. Red tea is made from the same kind of tea-shrub, and is of a brownish-black, rather than a red, colour. The infusion is certainly of a deep-red colour, and this may be the origin of the name *Hung-ch'a*, or "red tea," a name given to it by the Chinese. Green tea is made in Hupeh to some extent by picking at the very beginning of the season the fine hairy summits of the youngest branches of the shrubs. Brick tea is made from the clippings of the tea-bushes, the dust of black tea, and from any other description of leaf. Odd stories about blood and other substances being mixed with the tea-leaf and dust are perfectly unfounded. There are "large green bricks" of the coarsest sort, "small green bricks" made of a better kind of tea-leaf, and "small black bricks" made from good tea-dust. The shape of the tea which is used as a means of barter by the Mongol tribes is more like that of a tile than a brick. In making brick tea the leaves and dust are steamed, pressed in moulds of a uniform size, and carefully dried without access of the sun, or any other direct source of heat.

This tea goes to the Siberian, Buriat, Tungous, Kirghis, and Mongol tribes, who chop it up with salt and butter, or koumiss, after exhaustion of the leaf in the ordinary way. The people of Thibet wisely add a little carbonate of soda to the water used in brewing their tea from slices of the bricks.

If two or three leaves be picked from a tea-shrub and chewed in the mouth, very little in the way of marked impression is made upon the sense of taste. A grassy, slightly bitter, but scarcely astringent flavour is brought out in the mouth. The peasants picking the leaf or passing through the tea shrubberies are seldom seen to gather the leaf and partake of it, as schoolboys do of bramble leaves in English lanes.

Prepared tea-leaf is, in fact, a very different thing from the raw, growing leaf of the shrub. Chinese tea consumed in the country, and prepared by a single "firing," after drying in the sun, is also a very different article from the Congou tea prepared for the English market. On this account, Chinese statements and experience are of no great use in determining the effects of tea as consumed in western countries. Russian tea, which undergoes no special preparation for the short overland journey which it has to make, is more like the Chinese native tea in flavour. Foreign new tea—that is, tea prepared and still in China—is a very different article from the tea when placed in the teapots of English villagers, after being conveyed in an iron ship through the tropics, in large quantities of some ninety or more pounds weight. Tea is described in the Chinese pharmacology as cooling, peptic, exhilarating, rousing, both laxative and astringent, diuretic, emmenagogue, and in large concentrated doses as an emetic. It is used as a wash for sore eyes, ulcers, and wounds of all kinds. It is understood by Chinese physicians that the excessive use of tea renders people thin, anæmic, and weak-sighted.

Tea is taken by Chinese scholars and labourers to stave off the cravings of hunger until a convenient season arrives. Much of the so-called tea taken by the common people in China is nothing but very warm water. Hot water is often taken by them in large quantities when threatened with colds, fevers, and other acute or chronic diseases, apart from considerations of economy. They regard it as antidotal, corrective, solvent, demulcent, diluent, lenitive, stimulant, deobstruent, diaphoretic, diuretic, and lithontriptic in its effects. Such a dose is much more sensible than the inevitable "sixpenn'orth of the best French brandy" which the English rustic gulps down in the emergency of pain or some other symptom. Experience has taught the Chinese that weak tea is much better than cold and impure drinking-water. They are exceedingly particular as to the water used in tea-making. They prefer the comparatively soft water of their large muddy rivers, so often swollen by rain and the melting of snow. They object to tea made from lake water, as they consider it unwholesome and having a tendency to render the mind dull and slow.

(*To be continued.*)

THE CARBON CLOSET SYSTEM.*

By Edward C. C. Stanford, F.C.S.

This method of excretal removal is a modification of the Earth Closet System, in which some form of carbon is substituted for earth. The main objections to the application of the earth closet to large towns are,—the large amount of earth required, and the difficulty in obtaining the necessary supply.

By the use of charcoal the amount of deodorizer required is reduced to less than a fourth as compared with earth, and by carbonizing the manure removed, a constant supply is secured.

It is urged that the sewage difficulty may be enormously lessened, if not completely done away with, by treating the excreta of towns as we treat the ashes, removing each separately, and keeping all out of the public sewers. The quantity per head to be removed per annum may be fairly estimated at eight cwt., of which about seven cwt. represents urine alone. The amount of carbon required to perfectly absorb the whole of this quantity is less than eight cwt., so that in an ordinary household of ten persons, the total annual quantity required cannot exceed four tons, and the whole removal will probably, owing to the drying action of the charcoal, be about five to six tons.

The same household would use about twenty tons of coals, and probably send away four tons of ashes; much of this coal would have to be carried into the bedrooms. The charcoal method is so perfectly inoffensive that commodes may be placed, if desired, in every bedroom, without the least fear of odour or of danger to health. In this respect no water-closet can compete with it. The carbon closets are also arranged to be quite automatic, and require no attendance from within. The charcoal is introduced through an aperture in the roof into a reservoir at the top of the house; a closet on each floor draws on this source of supply, and the whole of the product is discharged in a dry deodorized state into a cemented vault in the basement story of the house.

The chamber urine is emptied into a small earthenware urinal on each floor, and from this a lead pipe conducts it direct to the vault, where it is absorbed by the charcoal from the closets.

The reservoir need only be replenished, and the vault emptied, once a year. The manure removed can scarcely be distinguished from cinders by an ordinary observer, and it is equally inoffensive.

The value of the material removed is about 1*s.* per cwt., or 8*s.* per head per annum. The household has the charcoal and the material removed without cost. A Company called "The Nitro-Carbon Manure Company (Limited)" has been formed in Glasgow (Office, 154, West Regent Street), to collect and treat the manure, and supply the charcoal. The manure is removed to the works and carbonized in revolving retorts driven by a steam-engine; the whole of the material is then converted into charcoal: and gas liquor, tar, and gas are distilled off and collected in suitable condensers. The charcoal increases at each reburning by the amount yielded by the excreta itself, a portion is returned to go on charging the closets, and the balance is available as manure. The charcoal produced is an animal charcoal resembling that made from bones, and contains all the phosphate and potash and soda salts of the excreta. The gas liquor furnishes ammonia derived from the animal portion of the food, and acetic acid derived from the vegetable portion. The tar and gas are used for heating purposes at the works. A new closet has been specially patented for the use of charcoal by Messrs. Pollock and Pollock, of Leeds, and may be obtained of the Carbon Closet Company, 46, Haymount Street, Leeds. This closet, which is figured in the *Engineer* of August 5th, 1871, and which may be seen at 154, West Regent Street, is expressly constructed for the use of powdered charcoal; it delivers a minimum but accurately measured quantity, and places it exactly where it is required. When these come more into use, the amount of charcoal used will be much less than that alluded to in this notice, the quantity will, it is expected, be nearly one-half the amount stated.

For large public works the carbon closet is invaluable; it is the only method of removal which the clumsiest of workmen cannot make offensive. The straw and waste with which the pipes of all workmen's water-closets are so constantly stopped do no harm here, and are all converted into charcoal on reburning. The principal shipbuilders on the Clyde are so impressed with these advantages, that they are pulling down large and expensive erections for water-closets to substitute carbon closets. Urinals on this system are constructed simply of vertical slabs six feet high and two feet wide, set in the form of a W on a large stone flag over a tank of charcoal; an occasional wash with a mop dipped in dilute hydrochloric acid, will make the slabs instantly and perfectly clean. The acid is cheap, and it cannot injure either the urinal or the charcoal. The process will be found fully described in the following papers by the same author:—

* Abstract of a Paper read before the Mechanical Section of the British Association. Edinburgh, 1871.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 11, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

APPRENTICESHIP AND THE PRELIMINARY EXAMINATION.

In the discussion concerning the obligations of the Pharmaceutical Society in respect to provincial education, which is now being carried on with fresh vigour in our columns, one point has been urged that is worthy of the serious consideration of all pharmaceutists who contemplate taking apprentices, namely, that on receiving apprentices they should make it an indispensable condition that the pupils should have previously passed the Preliminary Examination.

At the meeting of the British Pharmaceutical Conference at Liverpool in 1870, the Registrar of the Pharmaceutical Society stated as the result of his experience that most of the failures to pass the Minor Examination arose from deficient elementary education, and he recommended that masters should require every youth to pass the Preliminary Examination before he commenced his apprenticeship. This view was concurred in by most of the speakers; and as the occasion was one on which the subject of the facilities for pharmaceutical education in the provinces was brought forward for discussion at the special invitation of the Council of the Pharmaceutical Society, we think the opinions then expressed should have great influence. The proposition has been advocated at various times in the columns of this Journal, and it was also the basis of a paper on the apprenticeship question read at the Edinburgh Conference by Mr. S. R. Atkins, as pointed out by that gentleman in his letter this week.

It is evident that pharmaceutists have no special obligations towards securing the education of those with whom they have not yet entered into business relations. There is a tendency in some of our correspondents to hold the body to some extent responsible for the large proportion of failures at the Preliminary Examinations; and reflections are made upon certain towns that are supposed to have failed in their duties. But this is only true to a limited extent,—to the extent of the proportion of candidates who have entered the business before passing their examination. The fact that thirty-seven per cent. of candidates failed to pass a test that might justly be demanded from a lad who had received a fair education may be, and undoubtedly is, an indication of the great absence of sound teaching in this country, but we do not see that it involves any reflections upon pharmaceutists except as members of the commonwealth.

Were this policy generally followed by employers throughout the country, not only would the work to be done in providing means for education be greatly limited, but the supply of men who, supposing them to have had ordinary opportunities, have proved their unwillingness or incapacity to learn, would be stopped at its source, and a more successful result secured. Although it is pleasant to remember the unselfish and disinterested nature of all the educational efforts of the Pharmaceutical Society since its foundation, it will not be out of place to remind employers that apprentices secured under the conditions suggested are more likely to turn out valuable servants than those from whom no such examination is demanded.

We take this opportunity of stating that there is no desire on the part of the Council of the Pharmaceutical Society, in the case of the Preliminary Examination, to re-examine a candidate who has already proved his qualifications. Certificates of having passed the Local Examination of the Universities of Oxford, Cambridge or Durham, the examination of the College of Preceptors, or that of any legally constituted examining body previously approved by the Council, provided Latin and arithmetic be included in the subjects, are accepted in lieu of this examination.

A fortnight since we called attention to a notice of motion by Mr. Gay, at the meeting of the Council of the Royal College of Surgeons. This week we are informed by a correspondent that, at a recent Preliminary Examination of medical students in Glasgow, only twenty-eight passed out of fifty-six; and, moreover, that only eight of the whole number went up then for the first time. We mention these facts, not as matters for congratulation, but as showing that the Pharmaceutical Society is not singular in its experience.

SIR ROBERT CHRISTISON, BART.

Rarely has a better merited compliment been bestowed than that of the baronetcy just conferred upon this distinguished pharmaceutist and physician. Our readers are so familiar with the peculiar services rendered to toxicology and materia medica by Sir Robert Christison that we may absolve ourselves from any detailed reference to them here. But as a citizen, and above all as an academic functionary, Sir Robert has claims to respect and gratitude which ought to be known beyond the immediate locality in which they were earned.

Probably there is no man in Edinburgh who has done more for the reputation of the city and the efficiency of the University than he. The high professional tone he has kept up in the Senatus has been paralleled by the enlightened and active public spirit he has manifested in the promotion of municipal interest. If there is anything that can add to the gratification with which we announce the honour just bestowed upon Sir ROBERT, it is the reflection that he has received it, not at the conclusion of his career, but at a time when he is still full of that intellectual and physical energy which may be expected in the future to equal, if not excel, its achievements in the past.

PHARMACEUTICAL GRIEVANCES IN THE UNITED STATES.

ON several occasions during the last twelve months we have recorded attempts, more or less successful, that have been made in various States of the American Union to obtain the enactment of laws for the regulation of the practice of pharmacy. Doubtless part of the legislation proposed has been very crude, but the way in which the "Drug Clerk Bill," recently passed by the legislature of New York,* is being carried out, will probably cause a temporary cessation in some of the efforts to obtain State recognition, and lead to a careful revisal of proposed Bills previous to bringing them before the respective legislatures.

One serious ground of objection to the New York Act, by the druggists of that city, is, that the examining board have decided not to admit the diplomas of American or foreign schools of pharmacy as evidence of qualification, and that all candidates shall undergo an examination in chemistry, poisons and their antidotes, practical pharmacy, officinal botany, the adulteration of drugs and prescriptions. Another objection is, to the fee of thirty dollars demanded, which is roundly denounced as extortionate, and an opinion has been expressed by some New York druggists that the law was concocted and forced upon them, not with the view of benefiting society, but to afford emolument to a few political partisans. Consequently an "Apothecaries' Union" has been formed, having for its object to test whether a law which ignores diplomas granted by the New York and other chartered colleges, and in effect "legislates men out of the business they have followed for years under solemn legal sanctions, charters, and guarantees," is constitutional.

In England, while most people rejoice when they hear of an increase in the revenue, the collector of revenue is certainly not very popular, and few persons covet his frequent interference with their business. Thus pharmacists in this country will be able to sympathize with their American brethren, who seem just now to attract more than a fair share of his attention. We learn from the *American Journal of Pharmacy* that, until recently, imported perfumery in small packages, as originally put up by the makers, could be sold unstamped, but it has now been notified that it may only be so sold while in the original or unbroken packages, as entered at the Custom House. This regulation will, in practice, nearly abolish the sale of small original packages, as each bottle will have to be stamped before sale by the importer of the larger parcel.

Again, a few months since the revenue assessors visited a number of pharmacists in Philadelphia, and induced the proprietors to stamp their shop-bottles, from which perfumery and toilet articles were retailed, equivalent to the stamp duty of the retail value of their contents. The revenue commissioner, however, has since decided that the law does not authorize this practice, but that it "requires the stamp to be affixed to the bottle, or other enclosure, in which the article is sold or delivered, even though the bottle or enclosure may be furnished by the purchaser." As the law also requires perfumery to be stamped in proportion to the full retail value of the vessel and its contents, a rather ludicrous result would follow the presentation by a luxurious customer of a valuable fancy bottle to be filled with a few cents' worth of perfume.

* Vol. i. pp. 773, 890.

WE are requested by the REGISTRAR to state that the letter from "SPES," which appeared in our last issue, and which referred to the number of failures at certain places in the last Preliminary Examination, contains some inaccuracies. "SPES" appears to have fallen into the error of supposing that the published "List of *Towns at which Examinations were held*, with the Numbers of Candidates annexed" (p. 329), also represented the places at which the *candidates resided*, and, comparing it with the list of names and residences of those who passed (p. 328), he thus arrived at conclusions which are incorrect. For instance, at Swansea, five candidates presented themselves for examination, none of whom resided in that town, although it happened to be the nearest centre for them. All of these passed, but as their addresses in the list do not appear as "Swansea," "SPES" gives them as failures. We append "SPES'" list corrected by the REGISTRAR:—

	Candidates examined.	Candidates passed.	Candidates failed.
London	30	17	13
Manchester	9	6	3
Birmingham	2	0	2
Derby	4	4	0
Peterborough	4	0	4
Swansea	5	5	0
Taunton	4	1	3
Aberdare	3	2	1
Aberdeen	5	2	3
Carmarthen	3	1	2
Chester	3	0	3
Wolverhampton	2	0	2
	74	38	36

AT the recent meeting of the American Pharmaceutical Association, the following gentlemen were elected Honorary Members:—Professors REDWOOD and ATTFIELD, of London; HENRY B. BRADY, Esq., of Newcastle-on-Tyne; M. LÉON SOUBEIRAN, of Sèvres; MM. AUGUSTIN DELONDRE and A. CHEVALLIER, of Paris; Professor A. DUFLOS, of Breslau; Professor H. LUDWIG, of Jena; and Herr ANTON V. WALDHEIM, of Vienna.

Transactions of the Pharmaceutical Society.

The following donation has been presented to the Museum:—a finely crystallized specimen of Bromide of Potassium, by Messrs. Hopkin and Williams.

Provincial Transactions.

THE NORTHAMPTON CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

A Meeting was convened by the assistants of this town on the 26th ult., for the purpose of forming the above association, the object being for mutual improvement and advancement in pharmaceutical knowledge of themselves and the apprentices. Mr. MASTERS was called to the chair, and, after a few preliminary remarks on some of the advantages hoped to be gained, introduced E. F. Law, Esq., J.P. (a gentleman well known throughout the town for his scientific knowledge), who attended by special request of the preliminary committee, and gave an instructive address, which was well calculated, from the variety of interesting points in science touched upon, to stimulate and encourage those present in the diligent pursuit of knowledge, and the determination to overcome all obstacles in their path. The speaker was very earnest in pointing out the mistake persons made in attempting to overthrow religion by the aid of science, and impressing his hearers with the importance of not being content to know what nature's laws were, but why they were. As a beautiful example of the wisdom and prevision of Providence, he mentioned the peculiarity of water expanding after it has passed a certain degree of cold; and held that Professor Tyndall, in his treatise on heat, was incorrect in stating that an iron bottle was broken by the same rule when molten bismuth was poured in and allowed to cool; he contended that the subjects were not analogous. The speaker concluded his eloquent and appropriate address by wishing every success to the association.

A vote of thanks having been proposed to Mr. Law by Mr. HESTER, and seconded by Mr. LESTER, was carried with acclamation. The meeting was adjourned until Monday, Oct. 30th.

On the latter occasion the following officers were elected for the twelve months, commencing Oct. 1st last:—Mr. Masters, President; Mr. Tigar, Secretary and Treasurer; and a Committee consisting of four assistants and one apprentice was then formed, namely, the President (Mr. Masters), Messrs. Tigar, Druce and Stedman as the former, and Mr. Cross as the latter. They were instructed to prepare a code of rules, and arrange the evenings, etc., for the holding of classes or other meetings most suitable to the general assistance and advancement of members preparing for the several examinations.

At a subsequent meeting of the Committee a code of rules was agreed upon, and a subscription fixed at five shillings annually. It was determined to hold classes on Monday, Wednesday and Thursday evenings. On Monday, from half-past eight to half-past nine, chemistry (following Attfield's 'Manual of Chemistry'), taken by Mr. Tigar; from half-past nine to half-past ten, pharmacy, etc., by Messrs. Tutton and Lester. On Wednesdays, the same time, the first hour, botany, by Mr. Druce; the second hour, materia medica, by Mr. Ashby. On Thursdays, an hour will be given by a competent person to those preparing for the Preliminary examination. The President, by virtue of his office, to superintend all the above classes.

Through the kindness of one of the masters, a room in his own establishment is being prepared for the use of the association at his own cost. This was not the only kind offer of a room, but, being the first, was accepted. As soon as the room is finished, which will be in about ten days, the above classes will at once commence.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The usual fortnightly Meeting of this Association was held in the West Hall, Anderson's University, 204, George Street, on Wednesday evening, 1st inst.; Mr. THOMAS DAVISON, President, presiding. The meeting having been duly constituted, the following donations were announced, viz.:—Annual Subscriptions of one guinea from Messrs. W. and R. Hatrick and Company, and 10*s*. from Dr. A. M. Robertson. A letter was read from Daniel Frazer, Esq., offering five pounds to start a fund for the purpose of establishing a museum and library, which was left to the Council to consider and report upon. The PHARMACEUTICAL JOURNAL and *Chemists and Druggists' Advocate* were also laid on the table, and specimens of a poison bottle from Messrs. Hargreaves and Co., of Manchester.

D. Campbell Black, Esq., M.D., and E. C. C. Stanford, Esq., Ph.C., F.C.S., were elected honorary members, and Messrs. Townshend, M'Laren, M'Leod, John Young, A. M'Kay, D. J. Strang and Brady, were elected members.

"The best means of promoting the Education of the Pharmaceutical Student in Glasgow" was then discussed; the PRESIDENT opening the discussion by referring to the paper by Mr. Edward Smith, lately published in the PHARMACEUTICAL JOURNAL, on "Provincial Education." He quite agreed with the first two propositions, that all apprentices should pass their Preliminary examination before they became connected with the business, and thought that it could hardly be expected that they should provide classes for students who had passed their Minor; those he thought were in a position to help themselves. He then referred to some of the necessities of Glasgow, urging those requiring education to encourage the efforts already being put forward by the Association, and he had no doubt all would be benefited.

Mr. PATERSON followed, and after speaking in high terms of the address delivered on the previous night by Mr. Stanford, he spoke of early-closing, expressing it as his opinion, that until they had a more general shortening of the hours of labour, but little progress could be made in education.

Mr. KINNINMONT then addressed the meeting. He said it would no doubt ultimately be the case that apprentices would be required to pass the Preliminary before connecting themselves with the business, but they were in a transition state at present, and even those classes on chemistry and botany got up by the Association were merely a step to raise them to their proper position. He thought the time must come when it will be part of the agreement between employer and *employé* that time shall be allowed to attend classes, not supplementary classes in the evening, however, but the regular University classes during the day. He thought chemistry, botany, materia medica, and the toxicology of medical jurisprudence, should be the classes taken up by pharmaceutical students. As regards the classical education, there were so many opportunities in the city of getting it independent of the Association, he did not think it would be any advantage for the Association to inaugurate such.

Mr. HOWIE, of Edinburgh, was then called upon, and made a few remarks with regard to opportunities for pharmaceutical education in that city. He believed that some of the firms there had some such arrangement entered into as that referred to by Mr. Kinninmont, viz. students attending the regular University classes during the day, and that in these cases the University authorities had reduced the fee about one-third to students in pharmacy.

The discussion was continued by the SECRETARY, Messrs. BRODIE, CLARK, YOUNG, etc., at the close of which it was left to the Council to consider the propriety of drawing up a memorial for presentation to the London Council with regard to the question of grants of money from the Society to Provincial Associations for educational purposes.

Mr. J. L. M'Millan, seconded by Mr. Clark, moved that the name of the Association be altered to the "Glasgow Pharmaceutical Association."

Mr. Paterson moved the previous question, which was seconded by Mr. Brodie, and carried by a large majority.

Mr. Fenwick moved "That the Council take steps to obtain a grant of money from the Council of the Pharmaceutical Society," which was seconded by Mr. M'Millan.

Mr. Fairlie objected to the proposal, for several reasons. First, the largest sum of money that had yet been given was £10, a sum which would be of little service to them for the purpose to which they would be bound to apply it to. Secondly, their own resources had not yet been exhausted. Third, he believed that there was a possibility of some new arrangement being entered into by the London Council with respect to Provincial Associations; and for his own part he would like to see some closer bond of union between the parent society and provincial associations. He had always thought it would be a benefit both to the provinces and the trade generally, if Provincial Associations were affiliated to the Pharmaceutical Society in some such way as that propounded by Mr. Smith, and until such was wrought out, he would like the Society's funds to accumulate a little more. Fourth, their application at present might interfere in some way with the Scottish Branch of the Society at Edinburgh getting her due, which is at present much in need of assistance in more ways than one. And lastly, he believed they would hold a more independent position, and thus be able to keep a watch over the funds, in case of any indiscriminate distribution of them.

Mr. Kinninmont seconded Mr. Fairlie's amendment. He did not altogether agree with Mr. Smith in his idea of the Society sending out lecturers as examiners. He thought the benefits would hardly repay the expense. As regards the application for a grant, he objected to it on some of the grounds stated by Mr. Fairlie, but he also thought as an individual he could hardly ask for any assistance to the Association. All the money the Society made off him was somewhere about 1*s.* 6*d.* a year, after deducting the price of the Journal, postage etc., from his annual subscription; and until very recently Glasgow had not done much to benefit the Society generally. He had always thought, however (though he had not been successful in getting many to agree with him), that the Council might adopt some scheme of subsidizing the class fees of students attending the University only if they passed their examination. With reference to a library and museum, he thought that a consulting library should be the mode in which it might be adopted, and it should consist of books too expensive for individuals to purchase for themselves, and which most people would not read through, and being at hand for reference when any particular information was required. He therefore advised that the motion be withdrawn, which Mr. Fenwick did with consent of his seconder, reserving his right to bring it up at some future time.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

An ordinary Monthly Meeting was held in the Memorial Hall on Friday evening, November 3rd; Mr. J. T. Slugg, F.R.A.S., Vice-President, in the chair.

Mr. W. Wilkinson read the following paper on "Some of the Difficulties of Dispensing":—

We often meet with prescriptions which there is considerable difficulty in dispensing satisfactorily; and when I was asked to prepare a paper for this evening, it occurred to me that an account of some of these difficulties, with the method adopted to overcome them (where I knew it), was a subject on which an hour's discussion would not be altogether wasted. Of course I expect there are a good many here who know as much about the matter as I do, and perhaps more; but then my paper is not so much intended for them as for the younger members of our Association, to whom possibly a few hints on these matters may be useful, whilst I in return expect to hear something that may be useful to me.

Well, then, the difficulties we meet with in dispensing, or perhaps I should rather say in compounding, chiefly occur in mixtures, pills and ointments, and I propose to give some instances in each class, with the manner in which I have overcome them, when I have been able to do so.

With mixtures the trouble generally arises either from decomposition of some ingredient, or from non-amalgamation of the component parts, both these cases frequently arising from want of attention to the proper order of mixing: the latter are commonly of an emulsive character, consisting either of an alkali and oil with water or mucilage, and oil with water and other ingredients.

Here is one which I dare say many of you know pretty well:—

Pot. Carb. ℈ij
Aq. ℥viss.
Solve et adde—
Syr. Tolut. ℥ss
Ol. Amygd. ℥j.

That mixes pretty well if these directions are followed, but it does better if the salt of tartar is dissolved in an ounce or two of water, the syrup and oil added and well shaken, then the rest of the water.

Here is one with mucilage,—

Ol. Ricini ʒij
Sacchari ʒij
Mucil. Acac. ʒij
Aquæ ℥vj
Ol. Menth. Pip. gtt. ij.

This is best mixed in a mortar; rub the oil of peppermint with the sugar, add the mucilage and a little water, then the oil, and when these are well mixed, the remainder of the water gradually; you will then have a nice milky-looking mixture, without any globules of oil floating about. Always take care that the mucilage and oil are well mixed in this kind of mixture before the water is added, or you will have drops of oil floating about; and should any tincture or spirit form part of the ingredients, mix it with a little of the water, and let it be added last, or you may possibly find the mixture "come unmixed," for gum is precipitated from its solution by spirit; and do not forget that the oil is to be added to the mucilage, *not* the mucilage to the oil.

Here is a mixture of a different kind,—

Tr. Benz. Co. ʒij
Mucil. ℥ss
Liq. Morph. ʒj
Aq. ℥ij.

Now in this case, if you add water to the tincture, the benzoin is all precipitated and rises to the surface and it is impossible to mix it, but just shake the tincture well with the mucilage, then add the water and you are all right.

Here is another,—

Bals. Cop. ℥ss
Liq. Pot. ʒij
Sp. Lav. ʒiij
Sp. Nitr. ʒiv
Mucil. ℥ij.

The best way of managing this is to reverse the usual order of things, mix the liq. pot. with the spirits, add the balsam, shake together, then add the mucilage; so that you see chemical theory and dispensing practice do not always agree.

Mixtures with tragacanth powder or mucilage used to be very troublesome to me until I learnt how to manage them; this is another instance of an entire upset of orthodox dispensing practice.

The good old plan of using a mortar when powders form part of a mixture does not answer here, as every one who has tried it knows very well; but let the tinctures or spirits, if there are any, be put into the bottle first, the tragacanth powder added, all shaken together, then the water added, and your mixture is made without any trouble. If there should be no spirit of any kind in the mixture, half fill the bottle with water, add the tragacanth powder as the B. P. directs and you have no difficulty.

Then, again, vegetable powders, such as rhubarb or ipecacuanha, and compound powders, as Gregory, do not mix readily with water: well, in all these cases, the plan is to mix them first with any tincture or spirit there may be, and then there is no difficulty if there be no spirit. Mucilage or syrup is better than water. Bicarbonate of potash, or soda with citric acid, are often ordered together in mixtures, and the effervescence sometimes gives a good deal of trouble; but use an ounce or two of boiling water to dissolve the salts, the effervescence passes off directly, and you can finish your mixture at once.

The other day I had a mixture in which ʒij potass. cit. and ʒj ferri et quin. cit. were ordered with other ingredients; the potash happened to be alkaline and precipitated the quinine, which it ought not to have done, for the mixture should have been clear. It required about 15 grs. acid cit. to dissolve the quinine. Possibly some of you may have met with a similar mixture.

I once had a prescription which I had to make several times, but never succeeded in getting to mix, although I tried a different way each time. It was this,—

Glycerini ℥i
Mist. Acac. ℥ss.
Ol. Amygd. ℥j.
Syr. Aurant. ℥ss.
Liq. Calcis Sac. ʒss.
Aq. ad ℥viij.

And whichever way I mixed it, the liq. calc. and oil seemed to form a kind of insoluble soap, which separated immediately.

Now, with regard to pills. You all know the trouble they give sometimes; either they are too hard or too soft, or they will not mix, or they crumble to pieces in rolling out, or go contrary in some way or other, and are very difficult to manage satisfactorily. Some of the most troublesome masses to deal with are those containing essential oil,—peppermint, to my thinking, being parcularly cantankerous, more especially when ext. rhei is present. P. capsic. is another very unsociable article, and very often makes the mass crumble to pieces; but get a prescription with ol. menth. pip., capsic. and ext. rhei, and then you have a treat; indeed, it is hardly possible to give any general rule in these cases, for a good deal depends on the nature of the other ingredients; but if you find the mass crumbling or splitting to pieces on rolling out, it wants something to soften it a little in most cases.

Some time ago there was considerable discussion in the Pharmaceutical Journal as to the best mode of making creasote into pills, some recommending bees'-wax, and others something else. I find the best way is to rub the creasote, say 10 or 15 drops, with 10 grs. P. sap. cast., add the same quantity of light calcined magnesia, then sufficient liquorice powder. This forms a mass, which is sufficiently cohesive, and does not make the pills too large.

Ext. rhei is a particularly nasty article in pills, for it is generally either as soft as treacle or as tough as leather; but it seems an especial favourite with some of our Manchester prescribers. The way to overcome this difficulty is to powder the extract, and add to it a sufficient quantity of P. rhei to make up the weight lost in drying (which also prevents the powdered extract from running together again), and with a few drops of decoction of aloes the pills are made without any trouble.

Camphor is sometimes very troublesome in pills, especially if there be much of it; it seems to make the pills go hard and crumble in pieces; the best way to prevent this is to get the mass worked and rolled out as quickly as possible. Here is an example,—

Camph.,
Ext. Cinchon.,
Zinc Valer. āā ℈j.

This, if done quickly, and the ext. bark is tolerably soft, makes up without much trouble; but if left at all, it becomes quite hard, and requires a considerable quantity of mucilage to make it up.

When a pill mass is not much too soft a little P. tragac. is generally the best addition; but in cases where a large quantity of soft extract is ordered, this plan will not do. The only thing then is to leave out a portion of the extract, and use some dry powder in its place; for instance, we have often 2 or 3 grs. ext. hyosc. ordered with the same of blue pill. Nobody can make those into a satisfactory pill, supposing the extract to be in its usual state; but take about two parts of extract and one of P. hyosc., you then get a nice firm pill of the proper size. The same with ext. gent. and sulph. ferri, of which here is an example,—

Ferri Sulph. 12.
Ext. Gent. 48.
Ol. Cin. 12.

I should just like to see the prescriber make that into pills without any alteration. The only way to make it into a decent pill is to leave out about half the essential oil, and use nearly as much powdered gentian as extract.

I shall not detain you long with ointments, but there are two or three cases I will just mention. When you have an extract, such as belladonna, to mix with lard or any other fat, if you attempt to mix them together direct, there is considerable difficulty in getting a smooth ointment; but if you soften the extract first with a little hot water and rub it smooth, then add the lard, or whatever it may be, you have no trouble.

Glycerine is now frequently prescribed in ointments, and is difficult to mix. Well, supposing it be ordered with ung. zinci, as is often the case, do not use ready-made zinc ointment, but weigh the proper quantity of oxide, rub the glycerine with it, and then add the lard, you have then a good smooth ointment which does not separate; of course, the same plan can be adopted with any other powder. If there be no powder melt the ointment, but do not let it get too hot, and beat the glycerine in and stir till cold, it then mixes much better; but still, if there be a large proportion of glycerine, it will separate after a time.

Many other instances might be given, but the above are a few that I have met with in my own dispensing, and I have confined my remarks to them, hoping to hear during the evening something of the experience of others.

During the discussion which followed the reading of the paper, Mr. Siebold advocated the use of powdered gum instead of mist. acaciæ, which was so liable to decomposition. Mr. Siebold also suggested the addition of a small quantity of hyposulphite of soda to ung. potassii iodidi, to prevent its becoming discoloured; and alluding to the difficulty which dispensers felt in amalgamating watery extracts with fat, he said some lard manufacturers were evidently possessed of the secret, as some specimens of bladder-lard he had examined yielded, when melted, only 75 per cent. of lard.

Mr. Bostock observed that some lard manufacturers used considerably more pearlash than could possibly be needed for cleaning their vessels, and he understood it was sometimes added to whiten inferior lard.

Mr. Benger said the addition of a small quantity of alkali also rendered the lard capable of taking up more water. Commercial lard was very seldom fit for pharmaceutical purposes.

Some discussion followed on the best method of preparing pure lard, some gentlemen recommending that the "flare" be bruised in a mortar and washed in a stream of water, whilst others advised that it be melted at a low temperature (water bath) whilst very fresh, and without water.

A vote of thanks to Mr. Wilkinson closed the proceedings.

The next monthly meeting will be held on Friday evening, Dec. 1st. Tea at 7.30. Professor Williamson, F.R.S., will deliver a lecture on "The Natural History of the Minerals used in Medicine."

BRISTOL PHARMACEUTICAL ASSOCIATION.

The following are the arrangements for the monthly meetings of this Association, session 1871–72, which will be held at the Museum and Library, top of Park Street:—

1871—December 8—Lecture by Mr. Stoddart; 1872, January 12—Papers and Discussions; February 9—Lecture by Mr. Collens, Birmingham; March 8—Lecture by Mr. Warner, Bishopston; April 5—Lecture by Dr. Tilden, London; May 10—Lecture by Mr. W. Lant Carpenter, Clifton.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Meeting of Executive Committee, November 1st, 1871.

A resolution was carried unanimously to the effect that at all future Annual Meetings of the Conference the hire of rooms, the cost of printing programmes, and incidental expenses incurred by the Executive Committee, be paid by the Conference, and not by the Local Committee.

The secretaries reported that the whole of the manuscripts of the Year-Book of Pharmacy for 1871 and the Transactions of the Conference at Edinburgh were in the hands of the printer, and that the volume would be sent (by post only) to members in December. The London Secretary was directed to make the usual application to members for unpaid subscriptions, 1871–72, due in advance last July.

A notice to this effect will be found in the advertisement columns.

Mr. John Moss, F.C.S., was elected Assistant-Secretary.

The following were duly elected members:—

Appleby, Edward J.; Bevan, Martin L.; Blain, Arbuthnot H.; Booth, Richard; Bowling, J. H.; Clarke, Ingham; Croyden, C.; Dickie, James; Davies, J. R.; Davies, T.; Deering, Alfred; Field, James John, F.C.S.; Frazer, W., M.D.; Gill, J. W.; Green, G. E.; Grove, Harry; Hallawell, J.; Hilder, R. T., M.D.: Jones, C.; Ogilvie, George P.; Passmore, Francis; Pattinson, R. J.; Pinkerton, W.; Roper, H. E.; Rowell, Robert Henry; Simpson, R.; Snell, Charles Henry; Stooke, Arthur; Taylor, Richard; Tozier, William, L.A.H.I.; Wright, John A.

CHEMICAL SOCIETY.

November 2, 1871; Dr. Frankland, President, in the chair.

After the usual business of the Society had been transacted, a paper on "A Process for the Estimation of Fluorine," by A. Liversedge, A.R.S.M., was read. It consists essentially in distilling the fluoride with concentrated sulphuric acid and silica, passing the silicic fluoride which is evolved into ammonia, and then determining it as silico-fluoride of potassium. An interesting paper was then read by Mr. W. H. Perkin, F.R.S., on "Anthraflavic Acid," a yellow crystalline substance which accompanies artificially prepared alizarine, and with which the author finds it to be isomeric. The barium compound crystallizes from water in reddish-brown needles, which contain a considerable amount of water of crystallization. There was also a paper on "The Distillation of Wood," by Mr. Watson Smith.

SOCIETY OF ARTS.

Dyes and Dye-Stuffs other than Aniline.*

BY DR. CRACE-CALVERT, F.R.S.

Lecture I.

Red Colouring Substances.—Madder.

This well-known tinctorial substance may still be considered as the most important of all the dye-stuffs employed by calico printers, owing to the brilliancy of the colours, their permanence under the action of light and soap, and the wear and tear which fabrics so dyed can sustain, as well as on account of the variety of shade and colour that can be obtained,—one dyeing operation being sufficient to produce pinks, reds, purples, violets, puce, and black; and, notwithstanding the competition that madder colours have met with of late years from aniline dyes, I believe the quantity of madder consumed in England is quite as great at the present day as ever it was.

The employment of madder-root as a dye dates from the most ancient times, as is proved by the Egyptians using madder-dyed fabrics to wrap round their mummies. The Greeks and Romans were acquainted with it under the names of *Erythrodanon* and *Rubia*, and their modes of fixing it on cotton fabrics were the same as those now now employed, namely, aluminous salts for producing reds, and salts of iron for purples and blacks.

The plant which produces madder is an herbaceous one, and is called *Rubia tinctorum.* It bears a yellow flower, and a dark red berry fruit. The red colouring matter exists almost entirely in the cortical part of the root, little or no colour being found either in the epidermis or in the ligneous or centre part of the root. M. Decaisne and M. Edouard Koechlin have shown that the colouring matter in the fresh root is yellow, and becomes red under the oxidizing influence of the atmosphere. The same process goes on, to a certain extent, in the roots of the plant when they are allowed to remain several years in the ground, especially in chalk formations. In France, the roots are allowed to remain in the ground two or three years; in Turkey and the East, from five to seven. In the latter countries and in Naples, they are dried in the open air, but in Holland and France stoves are employed for this purpose. Naples and Turkey madders are imported in the root, and are known in commerce as Naples and Turkey roots, while those from France and Holland are ground, and sold under the name of French and Dutch madder.

* Cantor Lecture, delivered Tuesday, Feb. 7. Reprinted from the *Journal of the Society of Arts.*

One hundred parts of fresh root yield on perfect desiccation twenty parts of dried substance. The roots as imported always contain sixteen or eighteen per cent. of water; the fresh roots, therefore, give 24 or 25 per cent. of commercial madder. Dutch and Alsacian madder, after being ground, is stored in large casks, and kept for two or three years, when the colouring matter is developed, and its tinctorial power is much increased; if, however, it is kept five or six years, further changes ensue, and its value seriously decreases. French Avignon madder can be employed at once, although the quality is much improved by keeping it one or two years. The best Avignon madders are grown on lime formations. The roots that have a red colour are called *palus*, and those that are pink *rosées*,—the former being considered the finest. The value of these madders is in ratio to the fineness of their powder, the finer powder containing the most colouring matter.

The nature of the chemical changes occurring in madder during the time it is stored, and which so much improves its commercial value, was entirely unknown until the elaborate and interesting researches of Dr. E. Schunck, F.R.S., published in the year 1851. He succeeded in isolating a peculiar ferment called *Erythrozym*, which possesses the property of decomposing a substance called by him *Rubian*. Rubian may be considered as a glucoside (this name being given by chemists to compounds of sugar with other organic principles), and is decomposed by erythrozym into a peculiar sugar and *Alizarine*. Whether there are in the rubia-root several glucosides which unfold themselves respectively into sugar and one of the colour-giving principles, or there is only one glucoside, and its colour-giving principle as it is liberated gets successively oxidized into alizarine, purpurine, etc., is not yet satisfactorily determined. Still, this valuable discovery of Dr. Schunck has thrown much light on the subject, and has led to several important commercial improvements, to which I shall call your attention as I proceed. One hundred parts of dried madder-root consist of—

Soluble in cold water	55 parts.
Soluble in boiling water, and which contains the greater part of the colour-giving principles	3 "
Soluble in alcohol	1·5 "
Fibrous matter	40·5 "

I shall make no remark on the gum, mucilage, pectine, pectic acid, and pectates which the rubia-root contains, but state that the water extract contains also the yellow colouring-matter discovered by Kuhlmann in 1824, and called by him *Xanthine;* but this colour has never received any commercial application, from its want of brilliancy. Water also dissolves another colouring principle called *Chlorogenine*, which is decomposed by weak acids into sugar and a brownish-green matter. Both these colouring substances are sources of annoyance to the calico-printer, as they render very difficult the obtaining of pure whites in printed goods, and they dim the brilliancy of the shades produced by the combination of alizarine and purpurine with the mordants. Further, the cold water dissolves the sugar contained in the root, and on the Continent it is transformed into alcohol. The yield of alcohol varies with the nature of the root, and ranges between 7 and 10 lb. per cwt. of root. This fact shows that there is from 10 to 15 per cent. of sugar in the root.

Messrs. Julian and Roquet have based on the above facts a commercial process for preparing a purified madder, which they call *fleurs de garance*, of which several million pounds are now manufactured in France per annum. It not only yields brighter colours than the original madder, but, as it does not soil the white parts of prints, its use saves the printer much soap and labour. To prepare the *fleurs de garance*, the madder is mixed with eight or ten parts of water, and left for three or four days at a temperature of 75° to 80° F., when fermentation ensues, transforming the sugar of the root into alcohol, which is collected. The madder, deprived of all soluble substances, is dried, and ready for use. A hundred parts of madder yield from 55 to 60 per cent. of *fleurs de garance*. I may state, *en passant*, that the injury which Dutch and Alsace madders sustain when kept too long in casks is doubtless owing to the fact that, after the erythrozymic fermentation is completed, an alcoholic and lactic one sets in, which acts injuriously on the colour-giving principles.

I now proceed to lay before you the outlines of two interesting processes for extracting commercially the two useful colour-giving principles, *Alizarine* and *Purpurine*.

The first is due to M. Leitenberger, and is based on the fact that purpurine is soluble in water at 130° F., whilst alizarine only dissolves at 170° F. He mixes madder with water, and heats the whole gradually, by means of a jet of steam, to 130°, at which temperature it is maintained for some time. The liquor is then run off and filtered. To the clear solution, lime, or, still better, baryta, is added, when a lake precipitates. This is washed and mixed with hydrochloric acid. The purpurine thus liberated is thrown on a filter, washed, and is ready for use. The madder remaining from the above operation is dried and heated in close vessels with wood spirit, which dissolves the alizarine. This extract, thus obtained, after being concentrated by distillation, is ready for use. A hundred parts of root yield from two to three per cent. of purpurine, and four or four and a half per cent. of alizarine.

The second process, that of Professor Émile Kopp, is based on another discovery of Dr. Schunck, namely, that weak acids acts upon rubian in the same manner as erythrozym, unfolding it into sugar and alizarine. M. Kopp found, some years since, that sulphurous acid dissolved the glucosides of purpurine and alizarine, and applied this observation as follows:—600 lb. of Alsace madder are macerated for twelve or fifteen hours with 800 gallons of a weak solution of sulphurous acid, to which is added one-thousandth part of hydrochloric acid, to neutralize the earthy carbonates existing in the root. This operation is repeated three times. To the liquors, three per cent. of sulphuric acid are added, and the whole heated to a temperature not exceeding 140° F., when red-coloured flakes separate and gradually deposit, which, when washed and dried, are commercial purpurine. The liquor is then carried to the boil for a couple of hours, and allowed to cool, when a dark green powder is found deposited in the vessels, which, when washed and dried, is commercial alizarine.

This process has been carried out by Messrs. Schaaffer and Lauth for many years, and no doubt yields a larger amount of colour-giving principle than M. Leitenberger's method, the glucosides being doubtless more completely decomposed by the acids than by water alone. It has the further advantage of obtaining the colouring matters free at once, which have only to be washed to be ready for use.

The dyeing power of the alizarine thus obtained is equal to forty times its weight of madder, or ten times that of garancine. These colouring substances, except green alizarine, are not substituted for madder in the dyebeck, but are printed on the cloth and steamed, as will be described further on.

M. Kopp found that his green alizarine is a mixture of alizarine with chlorogenine; and that this latter body can be separated by treating the mixture with a light oil of tar, having a boiling-point of 300° which dissolves the chlorogenine. Alizarine is employed in the production of rich purples, whilst purpurine is used for reds and pinks.

Before describing pure alizarine and purpurine, I may state as a fact very interesting, although of no commercial value, that if superheated steam be passed over a preparation of a madder known as garancine, pure alizarine is volatilized, and may be easily collected.

Pure crystallized alizarine was discovered, in 1824, by MM. Robiquet and Colin, by treating madder with strong sulphuric acid, when they produced a black mass, which they called "charbon de garance," and which, on being heated at a moderate temperature, yielded crystals of alizarine.

In 1851, Dr. Schunck succeeded in isolating from madder a substance to which he gave the name of *rubian*. This he effected by filtering a hot decoction of madder on pure animal black, which is washed with cold water to remove chlorogenine. The washed charcoal is boiled repeatedly with alcohol, and the alcohol solution evaporated to dryness. The dry mass is dissolved in water, and acetate of lead added, which gives rise to a precipitate. This precipitate, when acted on by sulphuretted hydrogen, gives pure rubian in solution. When rubian is acted on, either by erythrozym or weak acids, it is decomposed, yielding, according to Dr. Schunck's paper, alizarine and water; according to M. Schützenberger, alizarine and glucose, or grape-sugar.

(*To be continued.*)

MEETINGS FOR THE ENSUING WEEK.

MONDAY Nov. 13. ......*Medical Society*, at 9 P.M.
London Institution, at 4 P.M.—"Nervous Matter: its Structure and Properties." By Professor Huxley. (Educational Course.)

WEDNESDAY Nov. 15. ...*Society of Arts*, at 8 P.M.—Opening Address by Lord Henry G. Lennox, Chairman of the Council, and Distribution of Medals.

THURSDAY Nov. 16. ......*Chemical Society*, at 8 P.M.
London Institution, 7.30 P.M.—"The Influence of Geological Phenomena on the Social Life of the People." By Harry G. Seeley, F.G.S.

Parliamentary and Law Proceedings.

ADULTERATION OF BREAD IN MELBOURNE, AND THE SCIENTIFIC EVIDENCE THEREON.

We have been favoured by a Melbourne correspondent with the subjoined report of an appeal case before the Judge of a County Court by a baker convicted of adulterating his bread, which may prove interesting to English readers. The whole of the bakers in Melbourne had had their bread seized by the police, and in every instance the Government analytical chemist found alum present. The bakers, as a rule, denied the practice, and protested against the correctness of the analysis.

William Johnson, Government analytical chemist, was sworn, and deposed that he examined a loaf of bread from Mr. Black's establishment, handed to him by the police.

How much alum did you find?

Alum itself is not *usually* found in bread, because in the process of baking alum gets decomposed. When it is mixed with bread, it is not possible to dissolve it out with water, and the only way is to ignite the bread, and recover it in the form of alumina, which is the base of alum. It was alumina I recovered from this bread, and I recovered a quantity equal to four grains of alum to the pound of bread. This was the smallest quantity in any of the eighteen loaves handed to me by the police. I only operated on four ounces of this loaf. In those four ounces I found three-tenths of a grain of phosphate of alumina, which equals four grains of alum.

Cross-examined by Mr. Billing as follows:—

When did you cut those four ounces out?—The next day after receiving the loaf.

How long did your analysing operations occupy you after that?—About six weeks. I was very busy, and could not devote my whole attention to it.

Where did you keep this piece of bread?—In my private room, locked up. It was wrapped in the same piece of paper the loaf came in. It was not possible for dust to get on it.

When did you burn it?—Not for some little time.

How did you proceed?—I first digested a small slice of the loaf in water mixed with logwood.

As a chemist, can you say that an infusion of logwood is considered a safe test?—No; but it will always indicate alum when it is present.

If there were other woods in the infusion as well as logwood, would not the same violet colour be produced?—Yes, as logwood would continue to act in the same way in the presence of other woods. But I may say that this was only a preliminary test, and that I abandoned it as not being satisfactory. For instance, there were some samples of bread that logwood did not affect, and I thought there was no alum in them; but they turned out the worst when I applied the next test.

You do not, then, consider logwood a safe test?—No.

You have changed your views on this since you gave evidence a week ago at the District Court?—Yes. I said it was a useful test then.

Did you not say it was an infallible test?—I might have done so, but do not think I did.

Does common salt contain alumina?—I will not swear it does not, as salt is of various qualities.

Well, then, take table salt or Liverpool fine salt.—That is quite pure. There is no alumina in it.

Do you know Hassall's work on 'Adulteration of Food'?—Yes; it is a good authority.

Do you differ from this passage, where it states that salt contains minute quantities of alumina?—No.

In the passage, he says that in two samples of salt there was alumina amounting to 0·05 and 0·06. What does that mean?—It means that in the first there was one-twentieth of a grain of alumina in one hundred grains of the salt.

How much alum would this be equal to?—One-ninth of a grain of alumina equals one grain of alum, or about this.

Taking the figures in Dr. Hassall's book as correct, how much alum would there be in a quarter-ounce of salt?—About nine-twentieths of a grain of alum in about one hundred grains, or nearly half an ounce of salt,—a fraction less than half a grain in fact.

How much alumina did you find in this bread?—One thirty-ninth of a grain. What I found was in the condition of phosphate of alumina. Making the calculation from it, and allowing one-fifth for error, I worked it out to four grains of alum to the pound of bread.

Were you sure it was all phosphate of alumina, and not other salts?—Yes, quite sure.

You know Muspratt's 'Analysis of Salts'?—No. He is no authority.

Supposing that he is no authority, would you think it impossible for salt to contain alum if in his work he gives instances?—No. He is a great compiler, and would be likely to be correct.

Do you know if potatoes contain alumina?—Yes; they do.

Have you ever found alumina in salt?—No.

How much alumina is there in potatoes?—Since the case at the District Court, I have found a quantity equal to eight grains of alum to the pound of potatoes.

Have you ever analysed the Yan Yean water the bakers use?—Yes.

Any alumina in it?—About one grain of silicate of alumina in a gallon; sometimes more.

Would there not be more in the winter time, when this loaf was made, owing to the muddiness?—Yes. There would be considerably more clay, or silicate of alumina, in the water then.

Have you ever analysed yeast?—Yes. Since the cases were heard at the other court, I have found seven-tenths of a grain of phosphate of alumina in two ounces of yeast, which is equal to nineteen grains and a fraction to the pound of yeast.

Do you believe Mr. Black put alum into his bread when he says he did not?—I do not think he did.

Might not the four grains of alum be easily accounted for by the presence of alumina in the ingredients naturally?—I do not think that more than half of the alum found could thus be accounted for. But I do not believe the bakers put alum in their bread, and I have good reason for believing it was in the flour. I examined six samples of flour, and found alum in all of them, in quantities varying from eleven grains to twenty-eight grains to the pound of flour. The amount of alum in the flour did not correspond to the amount in the bread. In one case, for instance, there were eleven grains of alum in the pound of flour, and only two grains in his bread; and in another only five grains in the bread, while he had twenty-eight grains in his flour. They must have more than one lot of flour.

His Honour Judge Cope then asked if the quantity alleged to be found over what Mr. Johnson had stated might be in the bread naturally would be unwholesome or injurious to the consumer?—The reply was that it would not.

His Honour then said that it was possible that such a small quantity, that nothing short of a scientific test could discover, might have got in accidentally or unavoidably, or without the defendant's knowledge or consent, in which case he was not liable. It seemed to him that the millers were, according to Mr. Johnson, more to blame than the bakers, and should have been proceeded against. The conviction was quashed, but without costs, as he considered the appellant must pay for the accidental introduction of the alum.

In the next case—one similar—Mr. Johnson stated that he had discovered the equivalent of $18\frac{1}{2}$ grains of alum in each pound of bread.

Cross-examined:—How much alumina did you find in this bread? I found phosphate representing $1\frac{3}{10}$ths of a grain of alumina, which equals eighteen grains in the pound.

This case was decided against the baker, as his Honour held that such a large quantity as eighteen grains to the pound could not have got into the bread accidentally.

Suicide of a Chemist.

On Saturday morning last Mr. Corbett Smith, chemist and druggist, of High Street, Bromsgrove, was found dead in bed by his housekeeper, who noticing that he did not come down as usual to open his shop, went into her master's room to ascertain the cause. An inquest was held upon the body the same afternoon, when, from the evidence, it appeared that deceased, a bachelor, aged forty-one years, and well known as a man of a jovial and easy temper, had been drinking rather of late. On Friday he was more than usually excited, and rather unsettled in his mind and manner, and when he returned home, after spending the evening out, about twelve o'clock, he was not sober. He was not seen alive after that time, and when found in the morning had evidently been dead some hours. On the table in his sitting-room was found an ounce-bottle half full of prussic acid, and by his bed-side, on a chair, was a medicine glass, which had contained some liquid. Underneath the candlestick was a paper, upon which was written in pencil, in deceased's handwriting, "From this world of long suffering and trouble I now make my exit. Friends, farewell." There were also some vague expressions. The light was put out, all the room was in perfect order, and deceased was lying with his hands folded upon his breast, as though in a deep, calm sleep. After hearing the evidence of Dr. Prosser and the other testimony, the jury returned a verdict "That deceased committed suicide by taking prussic acid whilst in a state of temporary insanity."—*Standard.*

Suicide by Strychnia.

On Saturday last an inquest was held in Westminster to inquire into the death of Mr. Antonio Bini, described as an Italian surgeon. Evidence was given that as the deceased, who had been in practice as a medical man in Castle Street, did not make his appearance, the door of his room was broken open, when he was found dead, and a glass containing a strong solution of strychnia on the table. The body presented the appearance of strychnia poisoning, which was confirmed by a *post mortem* examination. A verdict was returned that the deceased poisoned himself with strychnia while of unsound mind.

Poisoning by Laudanum.

On Saturday last the coroner for East Middlesex held an inquiry at Mile End, upon the body of a child, aged four days. It appeared that the mother had been taking medicine containing a small quantity of laudanum, and one empty bottle stood upon the bed-room shelf, another bottle containing one dose standing beside it. A small quantity of aniseed was fetched, and incautiously placed in the empty bottle, and the nurse, by mistake, gave the child a portion of the contents of the wrong phial, the consequence being that death supervened shortly afterwards. A verdict of "Death by misadventure" was returned.

Suspected Poisoning by Antimony.

At an inquest held last week at Bilston, Dr. Alfred Hill, of Queen's College, Birmingham, deposed that he found antimony in the stomach of a child aged eleven. The father is a puddler. Deceased was seized with excessive vomiting and purging, and died the same day. Sufficient antimony to cause death was found even after excessive vomiting. The mother denied having administered it in any shape. She had buried nine of her twelve children, and some of them died as this one did. The coroner has ordered the exhumation of the child last interred.

Review.

A Systematic Handbook of Volumetric Analysis. By Francis Sutton, F.C.S., Norwich. Second Edition. J. and A. Churchill. 1871. Pp. 377.

Although we find it difficult to admit without the proverbial grain of salt, the observation of a distinguished French chemist that "chemistry is a French science, having been founded by Lavoisier, of immortal memory," we feel bound to allow that illustrious man a position in the front rank of those who taught first the principle upon which all science, and the science of chemistry especially, relies, namely, quantitative exactitude. In the words of Sir William Thomson, "Accurate and minute measurement seems to the non-scientific imagination a less lofty and dignified work than looking for something new. But nearly all the grandest discoveries of science have been but the rewards of accurate measurement and patient and long-continued labour in the minute sifting of numerical results." This was the solid, if not the brilliant part of the philosophy of Lavoisier. It is true he was not the first who performed quantitative analyses, nor is his work distinguished by any very remarkable accuracy; but still we are indebted to him for systematically preaching the doctrine of quantity and practising it. After him came Berzelius, whose labour, so patient, so vast, and withal so exact, stands a monument alike to warn and to stimulate future generations of chemists. But these men and their successors for half a century worked by methods which were almost exclusively gravimetric. In the determination of quantity they have relied almost entirely upon the conversion of the substance into some form, either elemental or as a compound of known composition, which could be conveniently placed upon the pan of a balance and weighed. But unfortunately the separation of bodies one from another is a task which, though it has occupied the lifelong endeavours of some of the most acute experimenters, must yet be looked upon as far from complete.

In addition to this, suppose an element isolated from the companionship of its congeners, it must then, if it does not present the stability and fixity required for gravimetric purposes, be converted into one of its compounds, the composition of which is accurately known and which presents the necessary physical characteristics. Chemists found out at last, however, that some of the difficulties and much of the tediousness of gravimetry might be eluded by employing processes based upon another principle.

This principle has consequently come to be of great importance, and the art of volumetric analysis in high esteem. In English we have but one book devoted to this subject, and that is Sutton's 'Volumetric Analysis,'—a work which reflects the very highest credit on the skill and experience of the author.

Mr. Sutton explains the leading idea of volumetry as follows:—

"Suppose, for instance, that it is desirable to know the quantity of pure silver contained in a shilling. The coin is first dissolved in nitric acid, by which means a bluish solution, containing silver, copper, and probably other metals, is obtained. It is a known fact that chlorine combines with silver in the presence of other metals to form chloride of silver, which is insoluble in nitric acid. The proportions in which the combination takes place are 35·5 of chlorine to every 108 of silver; consequently, if a standard solution of pure chloride of sodium is prepared by dissolving 58·5 grains of the salt (*i. e.* 1 at. sodium 23, 1 at. chlorine 35·5 = 1 at. chloride of sodium 58·5) in so much distilled water as will make up exactly 1000 grain-measures; every single grain-measure of this solution will combine with 0·108 of pure silver to form chloride of silver, which precipitates to the bottom of the vessel in which the mixture is made. In the process of adding the salt solution to the silver, drop by drop, a point is at last reached when the precipitate ceases to form. Here the process must stop. On looking carefully at the graduated vessel from which the standard solution has been used, the operator sees at once the number of grain-measures which have been necessary to produce complete decomposition. For example, suppose the quantity used was 520 grains; all that is necessary to be done is to multiply 520 by the coefficient for each grain-measure, viz. 0·108, which shows the amount of pure silver present to be 56·16 grains."

And this is the general principle of volumetric analysis. We have not always to do with silver and chlorine, but the principle is applicable to all those cases in which a definite chemical reaction occurs, the completion of which can, by observation or by the use of some simple test, be recognized immediately and with precision.

"In alkalimetry it is the change of colour produced in litmus, turmeric or other sensitive vegetable colouring matter. The formation of a permanent precipitate, as in the estimation of cyanogen. A precipitate ceasing to form, as in chlorine and silver determinations. The appearance of a distinct colour, as in iron analysis by permanganate solution, and so on." It must be obvious that wherever the method is applicable a great saving of time and trouble is accomplished. Further than this, it has been abundantly shown that in a very large number of cases volumetric processes rival successfully, as to accuracy, the more tedious gravimetric operations.

All practical chemists, however, know that volumetry has, like gravimetry, its defects, and we think Mr. Sutton has exercised a very laudable and judicious moderation in limiting the number of processes which he recommends in this capital book of his. A great defect with which special books are so often chargeable is that the authors endeavour to extend their subject beyond its true and legitimate limits, and to give to it a wider generality than it has any right to.

Sutton's 'Volumetric Analysis' is known in every laboratory where technical chemistry is practised, but we fancy some of his former readers will hardly recognize their old friend in the magnificent volume into which he has developed. The book is very considerably enlarged, "the modern system of atomic weights has been adopted in the present edition, but the alteration is in many cases merely a nominal one, since the systematic arrangement previously in vogue facilitates the calculation of results and needs in no way to interfere with the theory of the chemical constitution of bodies."

Water analysis is a subject of entirely recent growth, and a very useful article is contributed to the volume by Mr. W. Thorp, principal assistant chemist to the Royal Commission on the Pollution of Rivers.

Those who are interested in gas analysis will be really indebted to Professor M'Leod for the very able and lucid article, illustrated by drawings from his own pencil, which occupies some seventy pages at the end.

Hitherto Bunsen's valuable 'Gasometric' has been the only book at the disposal of the student. For the English reader it is now superseded.

We cannot conclude without congratulating Mr. Sutton, as a *pharmaceutical chemist*, upon the production of this important addition to scientific literature.

Obituary.

We regret to announce the death, from phthisis, on October 16th, of Mr. John G. Dale, F.C.S., at the age of 31. The deceased gentleman was connected with the firm of Roberts, Dale and Co., Chemical Manufacturers, of Warrington, of the town council of which town he was a member. At the meeting of the Warrington town council on the 31st October, the mayor in a few feeling remarks, mentioned the loss the town had sustained, and moved that a resolution of condolence with the widow of their late colleague should be passed. After this had been supported by several other councillors, who all bore testimony to the great worth of the deceased, it was carried and ordered to be forwarded to Mrs. Dale.

We have also to record the death, on Monday, October 30th, of Mr. William Wootton, Pharmaceutical Chemist, of Wolverhampton, aged 44.

The following journals have been received:—The 'British Medical Journal,' Nov. 4; the 'Medical Times and Gazette,' Nov. 4; the 'Lancet,' Nov. 4; the 'Medical Press and Circular,' Nov. 8; 'Nature,' Nov. 4; the 'Chemical News,' Nov. 4; 'English Mechanic,' Nov. 3; 'Gardeners' Chronicle,' Nov. 4; the 'Grocer,' Nov. 4; the 'Journal of the Society of Arts,' Nov. 4; 'Food, Water and Air,' No. 1, for November; the 'Practitioner' for November; the 'Brewers' Guardian' for November; 'Transactions of the Odontological Society' for June; 'Journal of Applied Science' for November; the 'Doctor' for November; 'Bromsgrove, Droitwich and Redditch Weekly Messenger,' Nov. 4.

Correspondence.

THE PRELIMINARY EXAMINATION.

Sir,—On looking over the Journal of last Saturday, I am much surprised to find that your correspondent "*Spes*" has fallen into an error in his analysis of the candidates. In referring to this town, he says 3 candidates presented themselves, and the 3 failed to pass. This is not correct; and I hasten to inform "*Spes*" that two out of the three candidates did pass the examination, and received the Society's certificates to that effect. Doubtless "*Spes*" has fallen into the same error in his analysis of the other towns and cities, consequently his remarks cannot be relied upon. I may as well inform "*Spes*" that the two candidates' names were in the Journal of the 21st as follows:—

William Powell Watkins Blackwood.
William Davies Trecynon.

In justice to the above-named successful candidates I hope, Sir, you will insert this contradiction.

T. W. EVANS, *Chemist,*
Local Secretary to the Pharmaceutical Society.
Aberdare, November 6th, 1871.

Sir,—The letter of "Spes" on the last Preliminary examination gives some startling statistics; a further analysis of the list may be curious, if not instructive.

Examinations were held in 101 towns, with a total of 222 candidates; the percentage of failures, in round numbers, was as follows:*—

	No. of towns.	No. of candidates.	Passes.	Failures.	Percentage of failures.
Total	101	222	140	82	37p.c.
London	1	30	9	21	70
Country	100	192	131	61	32
11 towns, "Spes".	11	44	6	38	87
Other country towns	89	148	125	23	17

I give the figures for what they are worth; in some respects they are humiliating enough. I do not think, however, we can draw any very definite conclusions from them, for lack of other materials and standards of comparison.

It would be interesting to know what proportion of those plucked were fresh from school, and how many had been in the trade for possibly years, also what percentage of failures is found in the Cambridge and Oxford, London and Durham, Civil Service and other examinations. May there not also be some truth in the statement of Mr. Snell (Lond. Univ.), that the examination of the Society is behind the age, and that injustice is done to the candidates?

I should be sorry to palliate our own shortcomings by reference to the failings of others; it would not be wise to do so; but if the impression gains ground that the ordeal through which our apprentices have to pass is too severe the effect will be injurious, and many promising young men will be deterred from entering the trade. If our failures are not greatly in excess of what, under the circumstances, might be expected,—and I do not think they are in the aggregate,—we may take heart, and urge our young men to increased efforts to pass creditably. At present the trade is in a transition condition, and some time must necessarily elapse before we are equal to the new order of things.

If some such plan as that named by Mr. Ince was generally adopted, failure in the Preliminary would be reduced to a minimum. I could myself furnish several instances where young men, acting on my advice, have put themselves for three or four months under special instruction for a few hours weekly before going in for the Preliminary, not one of whom failed to pass.

I would suggest that, in future, you add a column to the Preliminary, showing the number of passes in each town; it would add much interest to the list, and show whether the same towns are constantly weak.

Hull, November 7th, 1871. JAMES BAYNES.

* It will be seen that, although the figures are correct in the aggregate, the details, being founded upon "Spes'" letter, are incorrect.

Sir,—I am saddened but not surprised at the large percentage of candidates "plucked" at the recent Preliminary examination.

Allow me, Sir, to re-enforce the argument which constituted the keystone of the position assumed in the paper on the apprenticeship question I had the honour of reading at Edinburgh, namely, that the Preliminary examination, or its equivalent, should be passed prior to apprenticeship commencing.

Want of time at the July meeting prevented, I know, several gentlemen from speaking, who were prepared to have discussed the subject, with the view specially of enforcing this particular point.

In papers on Provincial Education that have subsequently appeared in the Journal, the question has been casually referred to, and I am gratified by observing in the current number a more positive and distinct reference to it in the interesting paper on North German Pharmacy, by my friend Mr. Greenish.

Feeling strongly on the matter, I am convinced that the attention of our body must be yet more emphatically directed to it. I have letters now lying before me, from widely separated parts of England, stating the evil to be as rife as ever. Most imperfectly educated youths are being taken by men possessing neither the time nor the requisite qualifications to grind up their pupils for the Preliminary.

I am credibly informed that in some cases neither parents nor pupils are previously made acquainted with the compulsory tests of pharmacy, before deciding on the future calling of life.

Let the *public* thoroughly understand that the successful passing the test of a liberal education, in the form of one of the prescribed examinations, is a *sine quâ non*, to enter the vestibule of pharmacy.

Let *our brethren* distinctly understand that they sin against their own interests in accepting educational responsibilities they ought not to be saddled with, and one important step will have been secured towards that goal enlightened pharmacists are aiming at, and which our chartered status, together with the demands of society, render imperative. S. R. ATKINS.

Market Place, Salisbury, November 7th, 1871.

Sir,—I shall be glad if you will allow me to correct an error (a natural one I admit) in the statistics of "Spes," in the Journal for November 4th. He gives a list of twelve towns at which 74 candidates presented themselves for the last Preliminary, and finding only 15 names to the credit of those towns in the list of successful candidates, concludes that all the rest have failed, and says that such an unfavourable result reflects discredit on those towns. It would be so, if his conclusions were correct, but he has fallen into error by supposing that all the candidates resided in the towns in which they were examined. This is not the case. In Manchester, for instance, 4 only of the candidates reside in its neighbourhood, the others residing at Bolton, Burnley, Bury, Huddersfield and Rawtenstall. Three of these were successful, and their names appear in the list to the credit of their respective towns; so that there were 6 successful candidates out of the 9, instead of 3, as given by "Spes," and only 1 unsuccessful candidate from Manchester proper, instead of 6. The same remarks apply to the other towns, although I do not know the exact numbers.

I have been enabled to examine a correct table of the results in those twelve towns selected by "Spes," in which I found that the successful candidates number 38, instead of 15, and the failures 36, instead of 59,—bad enough indeed, but still showing that the large towns do not furnish such a proportion as he supposes.

As the reputation of Manchester candidates has previously suffered in a similar way from the same cause, I send a statement of the numbers who have presented themselves here at the last six examinations, with the results, as follows:—

Date.	Candidates.	Passed.	Failed.	Strangers Passed.	Strangers Failed.
June 20, 1870 . . .	3	3	0	0	0
October 3, 1870 . .	11	11	0	2	0
January 2, 1871 . .	16	12	4	1	0
April 3, 1871 . . .	12	4	8	0	0
July 3, 1871 . . .	14	12	2	3	1
October 10, 1871 .	9	6	3	3	2
	65	48	17	9	3

Showing a little over one-fourth, or 26 per cent. of failures, which certainly does not exceed the average.

I believe one cause of so many failures is to be found in the age of the candidates, many of whom are eighteen to twenty years of age or more, and were apprenticed before the passing of the Pharmacy Act, when no examination was expected; consequently, very little care was taken about their education, which we now find was too often lamentably deficient; and they find it very hard work indeed to acquire sufficient knowledge to enable them to pass; for it requires a very strong determination, and power of application which few possess, to enable a young man at that age, with no regular teacher and perhaps only an hour or two at night for study, to overcome the disadvantage he labours under from want of early training.

W. WILKINSON.

Cheetham Hill, Manchester, Nov. 7th, 1871.

Sir,—I wish to call the attention of "Spes" to an error he has fallen into in his letter on the failures at the last Preliminary Examinations, as far as this place at least is concerned. Taunton is represented as all having failed; that is not the fact, for although four presented themselves for examination, one of whom did pass, not one belonged to the town, and had they all passed, it would not have appeared in the return to which he refers. It is not fair, therefore, to look at the name of the town only.

I may mention that out of fifteen who have presented themselves this year at this centre, seven have passed, and although this is not what it ought to be, it is not quite so bad as "Spes" makes it appear.

Taunton, November 7th, 1871. HENRY PRINCE.

Sir,—Your correspondent "Spes," in his letter which appears in the Journal of last Saturday, makes a great mistake in reference to the five candidates who underwent the Preliminary examination at Swansea, on the 2nd ult. He states that all failed, and laments that this and other large places should turn out such a number of failures. "Spes" appears to draw his inferences from the fact that the candidates are not set down as residing in the towns in which the examinations took place. Those who came under my supervision lived at certain distances from Swansea, viz. two at Pontardawe; one at Llandilo; one at Aberavon; one at Llanelly, although entered for Leamington. If "Spes" will carefully examine the list, he will find no cause whatever for branding the district which I have the honour to represent, as all the candidates passed.

With the charge of casting darts, the "brethren" here have nothing to do; and as to "Spes'" advice to look at home, feed the flocks well and attend to their digestion, I trust that the chemists, as a body, are too honourable to neglect those under their charge.

THOMAS BREND,
Local Secretary.

Swansea, November 8th, 1871.

IMPROVED TINCTURE PRESS.

Sir,—I am pleased to find my opinion corroborated by my quondam assistant Mr. Watts, whose experience of other presses, fairly contrasted with mine, would be free from the prejudice allowed in favour of one's own hobby. But for the length of my letter last week, I purposed to add a few words on that very important part of the principle of screw-pressure—the inclined plane. In the PHARM. JOURN. Oct. 21st, I described the (theoretical) power of my press, with screw-threads one-eighth of an inch, and recommended an increase of power by reducing the threads to a twelfth of an inch; the advantage of this method of increasing the power being that it would also diminish friction (obviously by reducing the angle of inclination of the plane represented by the screw), but a conversation with a friend who denies my theory, and asserts that the increased power may be obtained quite as effectually by an extension of leverage only, throws a doubt on my accuracy, which may be shared by other readers of your Journal. I will consider the two cases separately. First, the twelfth of an inch thread with eight-inch levers, multiplies the power $8 \times 6 \times 12 = 576$ times, or twelve circumferences of the lever for each inch of depression. Now the eighth of an inch thread would only require eight circumferences of the lever for an inch of pressure, consequently, for the same multiplication of power as in the finer thread, the levers would have to be extended to twelve inches ($12 \times 6 \times 8 = 576$). Now, although these results are identical in theory, I opine that in practice they differ materially, the advantage being in favour of the smaller angle of the fine thread. I have heard objections to this thread as being too delicate to bear the enormous pressure I would put upon it; but I think not, for no manual power applied to a nut an inch deep, so as to extend it over quite a dozen threads, could do injury; although I grant that it might not bear the strain of applying the power direct to the male screw, as in the ordinary single screw-press; but of course care must be taken to ensure sufficient strength in all the parts of such an implement. The screws must be tempered after the thread is cut, as that operation causes brittleness, which must be avoided. The diameter of the rod should be about 0·6, or three-eighths of an inch, exclusive of the threads; this would require the angle of the inclined plane to be about 3° for the finer and 4° 30′ for the coarser thread. They may be represented with tolerable accuracy by two laths twenty inches long, the end of one raised one inch, and the other one inch and a half, when the greater power required to force a given weight up the steeper incline will be obvious. But is not this additional power given by the extended lever? It certainly is, but the result is accomplished only by greater friction than would be required to force the weight up the gentler incline. But I fear I am trespassing on ground belonging rather to the engineer or mechanician, than to the chemist, although I see no reason why the latter should not have something to say on a subject of much interest to him. The success of my double screw-press, in practice, leads me to hope that I may have the satisfaction of bringing into use a cheap, convenient and powerful implement, which, I believe, will far surpass anything yet introduced; but even if I am in error, I may do good, as before done by heretics in religion, politics or science, viz. by bringing out the truth.

C. A. STAPLES.

Fulham, S.W., November 6th, 1871.

"*Quærens*."—We would recommend you to add the tincture last; but we do not think that, under any circumstances, the mixture would present a satisfactory appearance.

"*Sigma*."—Use gelatine and glycerine as a basis. (See PHARM. JOURN. 3rd Ser. Vol. I. p. 446.) Or, if a few drops of water were added to the chloride of zinc,—making a saturated solution of it,—we do not think much difficulty would be experienced in preparing the pessaries.

H. Dunn.—The substance of your communication has already appeared in Dr. Tilden's "Chemical Notes to the Pharmacopœia" (PHARM. JOURN. 3rd Ser. Vol. I. pp. 564, 623).

J. R. Coldwell.—Aq. menth. vir. would generally be used.

"*Natator*."—(1.) Like ferri ammon. cit. (2.) It would be rather difficult to determine the quantity; but, to ascertain the presence of strychnine, try one drachm of it on a dog or a cat.

R. Lake.—Not if the tincture contain the proper quantity of quinine.

"*Nostrum*."—Melt the white wax, spermaceti and butter together. When these have partially cooled, add the powdered white lead and brandy; place the vessel in cold water, and stir well until cold.

J. T. R.—There is not the least probability that any of the present bye-laws relating to the examinations will be altered to suit cases like that of our correspondent.

R. R.—We have no further information upon the subject beyond that already published.

The Library and Museum.—We have received a letter from *T. S. M.*, in which he endorses the opinion expressed last week by "A Chemist's Assistant," that it would be of advantage to many if the Library and Museum were kept open on two evenings in the week until nine or ten o'clock. He also suggests that efforts to shorten the number of hours during which pharmaceutists keep their shops open should be made by the members of the Council in their respective localities.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. G. F. Schacht, Mr. D. Jenkin, Mr. A. Davison, Mr. J. E. Howard, Mr. W. L. Goldsworthy, Dr. Kidd, Mr. E. Nuttall, Mr. W. Moss, Mr. D. W. Scott, "Natator," "Juniperis," "Sabina," "Spes."

SHALL THE PHARMACEUTICAL SOCIETY CEASE TO BE AN EDUCATING BODY?

BY G. F. SCHACHT.

This question has many times been suggested by men who seldom allude to such themes for the sake of mere rhetoric, but, possibly because the time was scarcely ripe for its full discussion, it has hitherto failed to arrest the general attention of pharmacists.

It received, however, something like a formal re-introduction at the hands of Mr. Mackay in his recent address to the students; and I venture to express a few opinions upon the matter, in order to continue the discussion, for I fancy I detect certain indications that point to the necessity of some speedy modifications in the practical working of our Society, if not to such organic changes as appear, at first sight, to be involved in the position introduced by Mr. Mackay.

There appears to exist in the majority of minds the feeling that educational and examining duties ought not to coexist in the same body. The justification for this feeling is, probably, the fear that in his capacity of examiner, an individual is unduly tempted to show favour to those with whom he has been associated as teacher. The objection undoubtedly has weight, and, appealing as it does to a principle that touches the whole value of examinations, one is compelled to admit that the association of these two sets of duties in the same person or body of persons is not wise. Now, the law absolutely requires that the Pharmaceutical Society should examine; and though it is true the very individuals appointed to examine have nothing directly to do with teaching the candidates, yet the Council that appoints the Examiners appoints and pays the professional teachers also, and maintains a school within the walls in which the examining duties are carried on.

I must at once guard myself from being supposed to impute the smallest suspicion that favour has ever been shown to any candidate from this or any other influence. I simply discuss the subject in the abstract, and point out that the Society does fulfil the two sets of duties in Bloomsbury Square, and that there exists a feeling that this is not right.

On the other hand, it would be scarcely an exaggeration to assert that the basis of the Society's existence during its entire history, has been the one fact that it aimed to educate the pharmacists of this country to a higher professional standard; and the content with which its members have seen its large resources lavished upon the school at Bloomsbury Square, may be taken as a proof how fully they have recognized scientific education to be an absolute duty, and have approved the effort—partial though it was—towards its accomplishment. There is no doubt many of the founders and life members that have gone to their rest cherished the hope that their labour and money would help to the gradual exaltation of all chemists and druggists into a thoroughly educated body; and I feel persuaded the majority of those still living are attached to our Association chiefly by the constraining influence of a similar aspiration.

The Government, then, requires us to *examine*, and the members expect us to *educate*, and both demand that each set of duties shall be performed with perfect independence the one of the other.

The problem is, to devise a plan by which the double needs of the case can be satisfied. With deference, and in the hope that the proposition will be amply discussed, I suggest the following:—

I propose that the Society cease to appoint and employ any professional teachers, and cease to maintain any school-buildings or laboratories of instruction, except in the now unavoidable capacity of owners of property; and, in the place of its present partial system of education, I propose that it adopt a comprehensive one, framed upon the method employed by the Government in the Science and Art Department.

The details of this method are fully set forth in the 'Directory,' published by the Department annually; but its principles are probably familiar to most readers of this Journal, who will, therefore, know as well as I do, that they are simple and perfectly easy of application to our case.

The Society, supposing the proposition were adopted, would hold once a year, simultaneously over the whole country, an examination in chemistry, botany and materia medica. The questions would be arranged by a staff of professors (not teachers in any school of pharmacy) appointed by the Council, and the answers, having been prepared under the prescribed regulations, would be returned for estimation. The examiners would, in the first case, divide the candidates into two sections, the accepted and the rejected; the latter must try again. The former would be again divided into three classes, the boni, the optimi and the senior optimi. Each of the boni might be considered to have earned *for his teacher* a certain fixed premium, each of the optimi a larger premium, and each of the senior optimi, in addition to this premium for his teacher, a prize or certificate of honour for himself.

This is a broad sketch of the Government method as applied to pharmacy. It is unnecessary at present to enter further into details, but I may just say that I have been familiar with the Government scheme in its full working for some time, and know of no difficulty likely to arise in its application.

On the other hand, its adoption seems to me to offer a solution for most of the difficulties that at present surround the case. The Society would continue to exercise its examining functions as before, but would cease to identify itself with any educational staff or establishment. At the same time, it would promote the scientific education of the whole body of which it is the professed head, by a comprehensive scheme eminently practical and as eminently just. The scheme itself would serve to bind together, by the potent tie of an equal common interest, every individual in the trade, and thus vastly strengthen the hands of our executive in their efforts for further good; and by bringing all schools, whether metropolitan or provincial, into one common arena, there to be estimated and supported solely according to the results they can accomplish, not only would that admitted difficulty, "provincial education," disappear as a distinct and separate question, but local and individual enterprise throughout the whole country would receive an impetus that could not fail to result in a largely increased amount of good healthy educational work.

CHLORAL.

BY W. A. TILDEN, D.SC., F.C.S.

(*Concluded from page 342.*)

Chemical Characters of Chloral.—Chloral is a colourless oily liquid, of a rather disagreeable odour, very soluble in water, alcohol, ether, benzol and other solvents. When pure, it boils at about 201° F. (a little under 94° C.); sp. gr. at 18° C., 1·502, nearly identical with that of chloroform, but a little higher.

Mixed with the due proportion of water it becomes hot, and sets on cooling into a crystalline mass of the hydrate C_2HCl_3O, H_2O. This substance, when slowly crystallized, forms rhomboidal prisms, but is usually met with in confused crystalline masses. It melts at 122°–123·8° F. (50° to 51° C.), and boils at a temperature which is always below 212° F. (100° C.), but which is estimated by different observers at various points between 203° F. (95° C.) and 210·2° F. (99° C.).

Hydrate of chloral contains 89·12 per cent. of chloral and yields by decomposition by an alkali, 72·20 per cent. of chloroform. Its aqueous solution should give no turbidity with nitrate of silver.

Chloral, mixed with any alcohol, furnishes a crystalline alcoholate; the formula of the ethyl-alcoholate, for instance, being C_2HCl_3O, C_2H_6O. This substance melts at 114·8° F. (46° C.) and boils at 234°–239° F. (112·5°–115° C.). It contains 76·22 per cent. of chloral, and yields, by the action of alkalies, 61·76 per cent. of chloroform.

Both pure chloral and its aqueous solution are said to dissolve many of the alkaloids, among others morphia, quinia and strychnia. It is also capable of taking up considerable quantities of some substances, such as camphor and carbolic and benzoic acids, which are by themselves but sparingly soluble in water. Chloral hydrate is miscible with glycerine.

Chemical Constitution.—Chloral appears to be purely an aldehyd; in fact, the aldehyd of trichloracetic acid. For it not only resembles ordinary acetic aldehyd in its general reactions, but these two bodies are convertible one into the other. Thus, like aldehyd, it forms a solid isomer, *metachloral*, into which it is for the most part converted soon after separation from the hydrate by sulphuric acid. This metachloral is a white amorphous body, quite insoluble in water, but gradually reconverted into the soluble form by ebullition with water, or by distillation. It is not at present known whether there exist other modifications corresponding to the liquid polymers of aldehyd.

Then it forms with ammoniacal gas a compound which corresponds to aldehyd-ammonia, and which possesses the same power of reducing silver in the form of a mirror when warmed with a solution of the nitrate.

Like aldehyds in general, it combines with bisulphites of the alkali-metals, and, when boiled with hydrocyanic and hydrochloric acids, produces a syrupy compound, probably analogous to lactic acid.

By oxidation, chloral is converted into trichloracetic acid, just as aldehyd yields, under the same circumstances, though with greater facility, acetic acid.

$$\underset{\text{Aldehyd.}}{C_2H_3OH} + O = \underset{\text{Acetic Acid.}}{C_2H_3OHO}$$

$$\underset{\text{Chloral.}}{C_2Cl_3OH} + O = \underset{\text{Trichloracetic Acid.}}{C_2Cl_3OHO.}$$

Notwithstanding this close general correspondence between the two, there is necessarily an important difference in certain properties and reactions, the existence of which must of course be referred to the presence of the three atoms of chlorine in chloral. Thus, the action of alkalies upon aldehyd is to give, under ordinary circumstances, resinous products; or, by a properly-contrived experiment, hydrogen and an acetate are procurable.

$$\underset{\text{Aldehyd.}}{C\left\{\begin{array}{l}CH_3\\H'\\O\end{array}\right.} + \underset{\text{Potash.}}{(OK)'H}$$

$$= \underset{\text{Potassic Acetate.}}{C\left\{\begin{array}{l}CH_3\\(OK)'\\O\end{array}\right.} + \underset{\text{Hydrogen.}}{H'H}$$

But chloral yields, by contact with alkaline solutions, chloroform and a formate—

$$\underset{\text{Chloral.}}{C\left\{\begin{array}{l}(CCl_3)'\\H\\O\end{array}\right.} + \underset{\text{Potash.}}{(OK)'H} = \underset{\text{Potassic Formate.}}{C\left\{\begin{array}{l}(OK)'\\H\\O\end{array}\right.} + \underset{\text{Chloroform.}}{(CCl_3)'H}$$

This replacement of hydrogen by chlorine also probably explains the deficiency in that eagerness for oxygen which is so characteristic of aldehyd. Aldehyd, moreover, forms no hydrate. Opinion is at present divided as to whether the hydrate and alcoholates of chloral are molecular compounds or not. The question is, whether in hydrate of chloral, for example, the molecules of chloral and water stand side by side without change, or whether in the act of union a single molecule is formed which comprises neither chloral nor water as such. On the one hand, it may be argued that dehydrating agents readily remove water from the hydrate, setting chloral free; and that even distillation of the compound causes a partial separation of the two. Further, that the alcoholate when treated with an alkali yields chloroform, a formate and alcohol. On the other hand, the alcoholate is stated to give, by the action of pentachloride of phosphorus, not chloride of ethyl among the products of the reaction, as it should do if it contained alcohol, but a compound, in the generation of which the elements both of chloral and alcohol are concerned.

The alcoholate is also represented as differing in its physiological action from the hydrate. Until better evidence, however, is adduced, it will be more convenient to regard these bodies as containing chloral and either water or an alcohol.

Action of Dehydrating Agents upon the Hydrate.—Sulphuric acid mixed with hydrate of chloral produces considerable depression of temperature. On gently heating, a separation of liquid chloral occurs, which after a time becomes partially opaque from the formation of metachloral. If a considerable excess of sulphuric acid is employed, there is produced another solid body, which has been named *chloralide;* the nature of which is, however, but imperfectly understood. It seems to result from the metamorphosis of part of the metachloral.

$$\underset{\text{Metachloral.}}{C_6H_3Cl_9O_3} = \underset{\text{Chloralide.}}{C_5H_2Cl_6O_3} + \underset{\text{Chloroform.}}{CHCl_3.}$$

Alkalies.—It has already been shown how alkalies effect the decomposition of chloral into formic acid and chloroform.

Ammoniacal gas unites with chloral to form, if kept perfectly cold, C_2HCl_3O, NH_3, the analogue of aldehyd ammonia: but if allowed to become heated, chloroform and formamide $(CHO)H_2N$ are produced.

Chloral unites with many of the derivatives of ammonia, amides such as acetamide and urea, and bases such as aniline, and, as already stated, many of the natural alkaloids.

Action of nascent Hydrogen.—By adding zinc to a solution of chloral hydrate, acidulated with hydrochloric or sulphuric acid, the chlorine is removed with substitution of an equivalent quantity of hydrogen. Aldehyd is thus obtained:—

$$\left.\begin{matrix}O\\H\end{matrix}\right\}C_2\left\{\begin{matrix}Cl\\Cl\\Cl\end{matrix}\right. + 3H_2 = \left.\begin{matrix}O\\H\end{matrix}\right\}C_2\left\{\begin{matrix}H\\H\\H\end{matrix}\right. + 3HCl$$

Chloral. Hydrogen. Aldehyd. Hydrochloric acid.

Considerable quantities of aldehyd might be thus procured, unless, as is probable, the whole, or part of the product, is in the form, not of aldehyd, but of its isomers.

Action of Oxidizing Agents.—Chromic acid and nitric acid both convert chloral into trichloracetic acid.

$$\underset{\text{Chloral.}}{C_2Cl_3OH} + O = \underset{\text{Trichloracetic acid.}}{C_2Cl_3OHO.}$$

Nitric acid of sp. gr. 1·2 appears to have but little, if any, action upon chloral hydrate, and, indeed, it dissolves in fuming nitric acid without any immediate change. With the latter, however, it gradually undergoes oxidation after a few hours, or immediately on applying heat.

Analysis of Chloral Hydrate.—Several methods have been proposed, founded upon the production of chloroform when the hydrate is agitated with alkaline solutions. If the experiment be performed in a graduated tube, the volume of the separated chloroform can be read off, and its weight calculated from this datum.

Details of the methods recommended will be found in papers which have been published in the PHARMACEUTICAL JOURNAL. Another plan, which is in some respects preferable to the others, consists in the direct observation of the amount of chloral liberated by admixture with warm sulphuric acid.

But these tests, though possessing a certain value, do little towards the detection of those other chlorinated bodies which may so easily occur, though only in small quantities, without suspicion. In fact, it has not been shown, by any published experiments, that the liquid which separates in the reaction with alkalies is really pure chloroform, or whether it may not also include products of the decomposition of those other bodies. Moreover, the alkaline aqueous superstratum is invariably coloured brown, and this alone is an indication either of the presence of foreign matters, or that a portion of the chloral is changed by the alkali into something other than the normal products, chloroform and formate. A qualitative test is therefore desirable, and nitric acid appears to me to be one of the most promising reagents. Some experiments upon the subject are, however, wanted.

Further, whenever the alkali method is adopted, it would be worth while to employ pure ammonia or lime, or potash if properly diluted, and in every instance, until experience has shown it to be useless, to ascertain if the aqueous fluid separated from the chloroform gives, with nitrate of silver, any very marked indications of chloride. The production of any considerable amount of precipitate will point to the probability that the sample has been imperfectly purified, and is open to suspicion.

It might be advantageous even to estimate, by means of a standard solution of silver (an easy operation), the amount of chloride left in solution by different samples, after treatment in the same manner. It is by no means improbable that a more accurate estimate might in this way be formed of differences of quality than is at present possible by the methods commonly in use.

DRUGS FROM NEW CALEDONIA.

Mr. Bavay, a French pharmacist, who has lived for a long time at the French settlement, New Caledonia, Australia, has brought home several drugs which have been described by L. Soubeiran as follows:—

Ouliépé is a resin obtained by mastication of the buds of *Gardenia ouliépé*, Vieill., *edulis*, Vieill., and *sulcata*, Gærtn.; it is used by the natives as a cement and for caulking ships; it has a yellow colour, an aromatic, disagreeable taste and a glossy fracture. It is met with in compact lumps, if obtained from the lumps, or as a yellow powder from quickly dried leaves and pounding them. Soubeiran thinks the ouliépé resin is similar to decamali from East India, obtained from *Gardenia gummiflora* and *lucida*, Roxb., and there used in the hospitals as a covering of wounds to protect them from insects and to absorb the smell from ulcers. The last-mentioned resin is often taken for eleme.

Kaori, a gum resin obtained from the trunks of *Dammara Moorii*, Lindl., *ovata*, Moore, and *lanceolata*. Yellowish or white, brittle, with a smooth shining fracture; on distillation it yields an essential oil of aromatic odour. It is soluble in alcohol and may be used as a varnish.

Morinda tinctoria, Roxb. From the bark of the root of this plant Bavay claims to have separated alizarine; the natives use a decoction of this root and of the leaves of a species of *Barringtonia* for dyeing skins red.

Peziza Auricula-Judæ, sometimes very abundant in New Caledonia, is an article of export to China, where this fungus is used as food, or, according to others, in the manufacture of varnishes.

Ocotea aromatica. The aromatic bark furnishes an essential oil of agreeable smell, somewhat like oil of wormwood and sassafras.

Santalum austro-caledonicum, Vieill., the *tibo* of the natives, formerly very abundant, has become very scarce, because the trees, on account of the fine aromatic yellow wood, have been felled to such an extent, that now only the stumps and roots left from former times can be utilized.

Myoporum tenuifolium, Forst. The wood of this tree is used as a substitute for sandal-wood; the fragrance of the fresh wood is very pleasant, but it soon loses it after being kept some time.

Andropogon Schœnanthos is cultivated in the plains of New Caledonia by the natives, who use it medicinally, and who believe it to impart a pleasant taste to the yam roots, together with which it is grown. The plant is closely allied to *Andropogon citriodorus*, from which the lemon-grass oil is obtained.

Melaleuca viridiflora, Gærtn., which is named *niaouli*, is no doubt the most interesting product of New Caledonia; the tree is found very frequently, but mostly isolated from other trees. The natives utilize the thin cork layers of the bark for technical purposes; the leaves serve the soldiers and colonists as a spice. The last yield on distillation a colourless or yellow, very aromatic oil, similar to oil of cajeput, of a sweet and piquant taste, soluble in water, but more so in alcohol.—*Journ. de Pharm. et de Chim.*, *March*, 1870, p. 242.

THE ACTION OF HYDROGEN UPON NITRIC ACID.

BY E. BOURGOIN.*

As the result of a series of electrolytic researches previously published, the author has shown that there is satisfactory ground for assuming that when nitric acid is diluted with a considerable quantity of water a hydrate of the formula $N_2O_5, 4H_2O$ is produced; notwithstanding that H. St. Claire Deville, from an examination of the action of zinc upon nitric acid, has assigned to the same body the formula $N_2O_5 . 2H_2O$. When this acid, in different degrees of concentration, is submitted to the action of the electric current, it is supposed to undergo decomposition in the following manner:—

$$N_2O_5 . 4H_2O = (N_2O_5 + O_4) + 4H_2;$$

oxygen gas alone being evolved at the positive pole, while the acid steadily concentrates at the same point. At the negative pole hydrogen is set at liberty, but this gas, finding itself at the moment of liberation in presence of a certain amount of nitric acid, reacts upon the latter, with results varying according to the concentration of the acid. The examination of this latter action is more especially the subject of the present paper.

I. When a very dilute solution, previously freed by boiling from dissolved oxygen, is submitted to electrolysis, pure hydrogen alone is evolved at the negative pole; the nitric acid during the whole period of the experiment not being sensibly affected by the nascent gas. The analytical results confirm this assertion.

II. When the solution is less dilute, corresponding nearly to the formula $N_2O_5 . 2H_2O + 12{\cdot}5$ Aq., the hydrogen evolved, at first pure, soon contains a small quantity of nitrogen, and towards the termination of the experiment, ammonia may be detected in the decomposing cell.

III. With a solution one-fourth of the preceding strength, $N_2O_5 . 2H_2O$, 38 Aq., hydrogen only can be collected at the commencement, as in the previous instance: the gas, however, soon contains nitrogen, which latter decreases gradually, till, having attained a maximum, it finally disappears. This reaction is explained by the fact that, during the experiment, the acid, becoming gradually weaker, is at length no longer able to evolve nitrogen. The liquid was carefully examined for nitrous oxide, which, owing to its ready solubility, would have remained in solution, but the results in this particular case were always negative.

IV. When the solution is much more concentrated, containing only 15 eq. of water, no hydrogen is evolved from the negative pole, although oxygen is freely liberated from the positive pole; the whole of the hydrogen set at liberty reacts upon the acid, and the products of this reaction remain at first dissolved. The solution surrounding the negative pole soon acquires a blue coloration, and then hydrogen, mixed with a small quantity of nitrogen, is slowly liberated. After some hours a new gas appeared, which gradually but completely replaced the hydrogen, and finished by disappearing in its turn, as shown in the accompanying table. The gas proved to be nitric oxide:—

Gas collected.	1 hour.	12 hours.	15 hours.	20 hours.	30 hours.	48 hours.	50 hours.
Hydrogen . .	98·96	92·5	—	69·1	83·1	98·6	100·
Nitrogen . . .	1·04	3·5	1·4	3·4	10·1	1·4	—
Nitric oxide .	—	4·0	98·6	27·5	6·8	—	—

Towards the termination of the experiment, the negative liquid contained a considerable quantity of ammonia, and possessed, moreover, the characteristics of an aqueous solution of nitrous acid: it reduced permanganate of potassium and chloride of gold, and when neutralized with an alkali, not only blackened a solution of ferrous sulphate, but disengaged ruddy vapours upon the addition of dilute sulphuric acid.

V. When the pure acid, $N_2O_5 4H_2O$ is electrolysed, the evolution of gas, at first *nil*, soon becomes extremely rapid, and the gas which is collected is entirely absorbable by a solution of ferrous sulphate: it is pure nitric oxide. After a while hydrogen makes its appearance, when the liberation of nitric oxide slowly ceases.

The foregoing gaseous mixtures were analysed by mixing them with oxygen, and then adding a solution of caustic potash; the excess of oxygen having been removed by pyrogallic acid, the hydrogen was determined by explosion in the usual way. In conclusion, the author states that these experiments show that nitrous acid, nitric oxide, nitrogen, and ammonia result from the reducing action of hydrogen upon nitric acid, and that they furnish additional evidence of the energetic action of hydrogen gas, when the latter is capable of exerting its power in the nascent state.

CINCHONA CULTURE IN THE EAST.

According to the last published official report recently received on the cinchona culture in Java for the second quarter of the present year, the number of cinchona plants of all ages, sorts and sizes, have increased during that period from 1,730,705 to 1,741,525. In April and May all the developed cinchona plants of the valuable sorts planted out in open ground were pruned, to the manifest advantage of the trees. This pruning yielded 2485 kilogrammes of bark, which was forwarded to Batavia in thirty boxes. The valuable kinds of cinchona-trees have not yet been regularly turned to account; hence it is no wonder that the Java barks exported so far have stood no comparison with the South American barks of commerce. A disease has for some time been affecting some of the trees; but it has been greatly on the wane during the quarter, owing to the favourable weather, and the repeated sprinkling of the diseased plants with a decoction of tobacco and a solution of the polysulphuret of calcium. In May and June an official commission visited the eight cinchona plantations, with the object chiefly of endeavouring to trace out the nature of the disease. A long and close investigation convinced them that it must be looked upon as arising from parasitic vegetation, whose origin cannot be pointed out with certainty, because it shows itself very irregularly under varying circumstances. However much this disease may hinder the undisturbed and natural growth of the plants, it does not, as a rule, kill the latter; many of them, though severely attacked, have been able to recover vigorously. It has also been ascertained that this disease is not peculiar or confined to the cinchona plants, for it has been observed elsewhere on other kinds. The preparation of the so-called quinium from Java barks of a fine quality promises to yield, for medical purposes, a substitute for the costly quinine. Therapeutical experiments made with this preparation during the previous year have given very encouraging results; and, although the experiments made in the State Laboratory at Wetteren to prepare quinium with profit cannot be looked upon as successful, they have succeeded elsewhere, and will be continued on a larger scale. Attention has often been drawn to the estimation steadily gaining ground for the alkaloids allied to quinine. The results of the experiments made in British India have been made public by the British Government. These results bear out the conviction that, as soon as an opportunity presents itself for the preparation of alkaloids in Java, the costly demands for quinine from Europe will speedily be brought to a minimum, for the Java barks, when fresh and gathered from healthy trees, contain abundance of alkaloids. A supplement to the report gives a sketch of the experiments made in British India.*

BOTANICAL DESCRIPTION OF CUNDURANGO.†

The cundurango or condor vine, a name derived from the two Quichua words cundur and ango, is a climbing vine resembling much in its habits the grape-vine of our own forests. Springing from the seed generally at an altitude of from 4000 to 5000 feet, and on the western exposure of the Andes, after growing to the height of three or more feet, a slim little stalk, it reaches out and finds some strong arm to lean upon; it prefers the tallest trees and clings closely to their trunks, winding firmly around them, following the growth to the extremity of their limbs; and sometimes, for want of other support, returning upon itself, weaving a curious rope of cundurango strands. The natives insist that there are two varieties of the vine, the amarillo or yellow, and the blanco or white; but careful observation failed to reveal any difference between the two, except in the colour of the wood; the leaves, flowers, fruit and seeds are exactly the same. To the critical observer the wood of one appears of a somewhat deeper yellow colour than the other; which I attribute to the more direct influence of the powerful rays of the sun, the blanco growing more in the shade. Both possess equal medicinal properties.

Cundurango vines of five inches in diameter have been found, but generally they are from one to three inches in diameter. They are quite flexible when fresh, but when dry very brittle; the bark, which is the part containing most of the medicinal properties, is, externally, of a greenish-grey colour, and has numerous small warty excrescences. When freshly cut, it gives an abundant milky viscous juice or sap; it is somewhat fibrous, and the cut portion of the dry bark presents small yellowish dots, easily distinguishable. The odour is balsamic, the flavour peculiar and decidedly an aromatic bitter. The leaves are large, sometimes reaching six inches in length by five in breadth, opposite, simple, entire, cuspidate, cordate, and of a dark green colour. The flowers are small, arranged in umbels complete, of valvate præfloration, five low stamens, sepals five, petals five, filaments small, the pollen collected into granular masses, the ovary double, the fruit—a pair of dehiscent pods—follicles, five inches in length, flattened on their inner sides and joined at the stem and vertex. The seeds are numerous, dark brown and flattened, each with a long coma attached to one end. The vine, in many particulars, evinces its relationship to the Asclepiadaceæ family—approaching the genus *Periploca*, or, according to the classification of Linnæus, the *Pentandria Digynia*.

These vines are found at the same altitude and on the same exposure of the mountains in nearly all the province of Loja, but those containing the most powerful medicinal qualities are probably most abundant in the mountains of the cantons of Loja, Calvas and Paltas, extending south towards the line between Ecuador and Peru. Judging from my own observation and the statements of the natives of that region, I believe the true cundurango, or that which I have described and which has given the wonderful effects upon cancer already known to the world, is not abundant. There are very many, some fifty or more, varieties of bejucos or climbing vines in Ecuador, several of which give a milky sap, and some may and probably do have medicinal properties more or less potent; several are known to be poisonous. The great difficulty of obtaining the bark of the genuine vine and transporting it over the mountains to the coast, and the high price which its medicinal properties will command, may operate to induce the export of the bark of many of these other vines which may be not only comparatively inert, but many of them positively injurious, an event much to be feared, and which, for the protection of the people whose necessities require them to use the medicine, should be scrupulously guarded against. The authorities of Ecuador will no doubt soon take the proper steps to prevent the exportation of any but the bark of the genuine vine. Of the value of the cundurango as a remedial agent, I fully assured myself while in the interior of the country, both by personal observation in some twenty cases of chronic diseases of the blood, and from natives who had used it, particularly from Señor Don Manuel Eguiguren, Governor of the Province of Loja, a man universally beloved and respected by all who know him, and whose kindness and invaluable assistance have placed me under lasting obligations to him. The cases of cure of chronic ulcers by the administration of cundurango which have come under his immediate attention, and which he testifies to and speaks of with such genuine enthusiasm, are truly marvellous, and entirely set at rest any doubts I may have entertained, and coupled with evidence presented from Quito, from Guayaquil, and all through the interior, establish beyond a question the value and efficacy of this newly-discovered remedy as an alterative and purifier of the blood. To the President, Garcia Morena, to our excellent Minister, Hon. Rumsey Wing, and to Señor Governor Eguiguren the world is indebted, for the most part, for this great boon—a knowledge of the existence and powers of cundurango; and to them Ecuador owes another jewel in her crown, whose place shall be next to that priceless one set there by the discoverer of cinchona bark.—*New York Druggists' Circular.*

THE PREPARATION AND PROPERTIES OF THE VARIOUS KINDS OF CHINESE TEAS.*

BY F. PORTER SMITH, M.B. LOND.

(*Concluded from page* 388.)

It will be remembered that the leaf used in the making of Congou tea (black) is first dried in the sun, and then compressed, so as to part with any superfluous moisture. This must lead to a concentration of the principles contained in the leaf. The tea-leaf is stored in bags, and generally subjected to a preliminary "firing" in addition to the formal "firing" previously described, in view of any delay which may occur during the collection of such large quantities as are necessarily prepared at one time for the foreign market. Certain chemical changes tending to the oxidation of the chemical constituents of the natural leaf must take place in the repeated exposure to a moderate heat, and during the storing together in loose heaps of the half-dried leaf freely

* See PHARM. JOURN. 3rd Series, Vol. I. p. 325.

† Extract from the Official Report of Dr. P. T. Keene to the U. S. Department of Agriculture; from N. Y. Drugg. Circ.

* From the *Medical Times and Gazette.*

exposed to the atmosphere. Nothing like fermentation ever takes place, as this would issue in the destruction of the leaf, which is carefully kept from becoming heated or mouldy during the process of making up the whole "chop." A kind of maturation occurs, issuing in the formation of more extractible matter, capable of solution and circulation. The final "firing" has something of the same effect upon the tea-leaf as the kiln-drying has upon the germinating barley passing into malt—it fixes the composition of the tea-leaf, and renders any further change as unlikely as undesirable. The tea-leaf is then at its best, and any idea of ripening upon the voyage is simply absurd. It follows from the low temperature at which the tea is dried that no empyreumatic products can be met with in properly prepared tea. And yet there is a degree of austerity produced in the ordinary black tea which causes it to produce nausea, sickness and diarrhœa when taken in the shape of a strong infusion prepared from the new spring tea just ready for the voyage to Europe. This is especially the case with badly-secured leaf, which may be assumed to have been purposely exposed to a high temperature in order to fit it for the foreign market. All or most of these effects pass off by the time that the tea reaches the foreign consumer. The more stable the tea, the better it will turn out. Any change on the voyage is for the worse, according to the experience of the most competent judges. Thirty pounds of the green leaf produce from eight to ten pounds of the sun-dried leaf. One hundred pounds of the sun-dried leaf lose eight pounds of weight in "firing," and produce ten pounds of stalks, fifteen pounds of tea-dust, and the rest good marketable Congou tea. New tea produces in China laxative effects upon foreigners, as prepared for exportation. This effect is not permanent. As a rule, black tea, under the same circumstances, has a decided diuretic effect, even in hot weather, when perspiration is abundant. It excites in many a strong craving for food, and causes a degree of sleeplessness. The narcotic effect of new tea is asserted by Johnston in his "Chemistry of Common Things," but has never been noticed. The large proportion of nitrogen in tea, amounting to nearly 6 per cent., prepares us to find powerful properties in it. That tea is a stimulant there can be no manner of doubt. This probably depends upon the presence of the theine, a soluble crystalline substance, which resists the moderate temperature at which the leaf is dried. The peculiar taste of green tea falsely suggests the presence of more than the usual amount of that astringent principle which, in the shape of tannin, is present in about equal quantity in both the black and green tea. The properties of tea as an astringent are turned to account by the Chinese, who prescribe it in diarrhœa when acidulated with vinegar. Cold tea, to which a small quantity of dilute sulphuric acid has been added, is an excellent diet-drink for use in hot weather when there is a tendency to diarrhœa. That the use of tea to a large extent has a peculiar effect upon the nervous systems of both animal and organic life there can be no doubt. This is the reverse of a sedative influence. Some of the craving of the Chinese for opium is connected with their incessant drinking of tea, especially upon an empty stomach. The effect of tea is to excite, and this property may be turned to excellent effect in cases of opium-smoking, and in uræmic poisoning. If good new Congou tea be given in the latter disease, there is the additional advantage of the diuretic effects of the infusion. In all cases in which coffee is most to be prescribed, tea is much more convenient, accessible and powerful. It is obvious that the high temperature at which coffee berries are roasted must be fatal to the presence of much caffeine, a principle identical with theine. This latter substance has been recently proposed by Mr. Lewis Thompson (*Medical Times and Gazette* for February 10, 1871) to be brought into use as a tonic remedy in typhoid diseases, neuralgic affections and in senile gangrene. Large quantities of weak tea, however, tend to the occurrence of sciatica and other forms of neuralgia. The experiments of Peligot seem to prove that, as might be assumed from the presence of so large a proportion of nitrogen, tea is, as the Frenchman said of the coffee, both "meat and drink." Old women who boil their tea-leaves are right, for they thereby extract much more of the theine. The antidotal power of tea, so strongly insisted upon by the Chinese, is worth a trial, especially in cases of poisoning by tartar emetic or corrosive sublimate. A statement appeared in an English paper, some few years ago, to the effect that tea is an aphrodisiac, and that its extensive use partly explains the fertility of the Chinese population. It is remarkable that, as the Chinese have made the subject of aphrodisiacs a very profound study, no reference is made to this effect in Chinese medical works. As Liebig has suggested that theine goes to make taurine, a biliary substance, it is possible that the spermatic secretion may be increased by a course of strong tea. Of the effect of tea upon the menstrual secretion the Chinese have no doubt. It may be that in this way the female population of Great Britain have actually hit upon a perfect cure for their "irregularities," as they are called in quack advertisements.

The use of tea in certain forms of dyspepsia is a common Chinese practice. If taken as a plain drink between meals, it seems to give tone to the stomach. It is obvious that the "tea" of our domestic tables, a compound of milk, sugar and much water, is not the article intended to be spoken of in these pages. The sooner *infusum theæ* is placed in the British Pharmacopœia as a recognized article of the materia medica, the more likely are we to place its employment upon a scientific basis, and thus to rescue a very important drug from the contempt of familiarity. A tincture of tea is not a desirable preparation, as theine is only sparingly soluble in cold alcohol. An extract of tea, carefully prepared, would be an excellent preparation for trying the effects of tea in the delirium of fever and the stupor of intoxication.

The Chinese are under the impression that foreigners are compelled by some instinctive necessity to send and buy the tea of the land of "the Glory of Summer." Of the influence of tea upon the sobriety of our countrymen and countrywomen there can be no doubt. When our poor people cease to waste their tea-leaves, and begin to eat them as a dish, like the people of Mongolia and Siberia, another important step will have been taken in the direction of completely utilizing the properties of this most important article of diet and medicine.

Brick tea might economically be introduced into use on board our ships of war, as it is cheap, portable, good, and much less perishable than ordinary tea.

THE PRINCIPLES OF GAS ILLUMINATION.*

(*Concluded from page* 386.)

With regard to the effect of heating the gas, it was stated that when the U-tube was immersed in boiling water (temp. 212°, the normal temperature being taken to be $64\frac{1}{2}$° F.), the illuminating power of the gas-flame rose from 100 to 104; and when melted paraffin was substituted for the water, and the temperature of the gas thus increased to 288°, the illuminating power rose to 118,—showing an increase of 18 per cent. in the illuminating power of the gas, in consequence of the rise of temperature.

Such results appeared to the referees inexplicable on any grounds yet known. From experiments made in connection with various plans of sulphur purification, it is known that when gas is raised to a high temperature a loss of illuminating power is incurred, chiefly from a deposit of the light-giving carbon elements of the gas.

* Abstracted from the Report of the Gas Referees.

But at any heat which does not thus alter the constitution of the gas, the only result of raising the temperature must be to increase its volume by expansion; and the effect would be that, if the gas were heated *after* it has passed through the meter, and the meter were made to pass a fixed quantity, then the heated gas, being enlarged in volume, would have to pass *more quickly* through the burner than if it were of the same temperature as it had when passing through the meter.

The question is one of considerable importance as regards the construction of burners; and two opposite views have been held on the subject,—the Leslie burner having been devised on the theory that the gas should be heated as much as possible before being ignited; while Mr. Sugg and others, more recently, adopt the opposite opinion, and make their burners, in whole or in part, of non-metallic substances, in order (*inter alia*) that the gas may be heated as little as possible. In order to test the accuracy of the results obtained at Munich, and, generally, to ascertain correctly what effect (if any) temperature has upon the illuminating power of gas, the referees made the following series of experiments (the temperature of the room being about 65°):—

A 12-ft. coil of half-inch metal pipe was placed in a water-bath; a metal pipe 18 inches long led from the top of the coil to the burner; and midway between the coil and the burner a thermometer was inserted in the pipe, in such a manner that the gas passed over the bulb. The water was then raised to the boiling-point (212° F.), but the thermometer only rose one or two degrees and remained stationary. Oil was then used instead of water, and the coil was lengthened from 12 to 56 feet; nevertheless, when the oil was raised to its boiling-point (about 400° F.), the thermometer in the gas only rose to about 79° F. Inferring (as will appear, too hastily) from this that the gas, in passing through the coil, failed to absorb the heat from the surrounding oil, large shot were introduced into the coil of pipe, in order to conduct the heat inwards, and bring the gas at all points in contact with heated metal. Even then the thermometer hardly showed any further rise of temperature; but it was incidentally observed that the quicker the gas was sent through the pipe, the greater was the rise of the thermometer,—although, of course, the gas was then for a shorter time in contact with the heated metal.

This fact at once showed that the stationary position of the thermometer was not so much owing to a difficulty in heating the gas in the coil, as to the rapidity with which the gas lost the heat so acquired, after leaving the coil. Accordingly, in the subsequent experiments, the pipe leading from the coil was surrounded by a jacket filled with boiling oil, and extending to within 2 inches of the point of ignition,—the thermometer being again placed between the coil and the burner. The effect of this change in the apparatus was that the thermometer at once rose to 296° F., the temperature at which, according to the experiments made at Munich, produced an increase of illuminating power to the extent of 18 per cent. An apparatus was then so constructed that the burner could be supplied instantaneously with cool and heated gas alternately, and any change of illuminating power, produced by a high or low temperature of the gas, could be readily noticed. But *the heated and the cool gas gave exactly the same amount of illuminating power.*

Indeed the heat acquired by gas immediately upon ignition is so great—the heat of a Bunsen-flame being estimated at about 1800° C. (3272° F.)—that the highest temperature at which it is practicable to supply gas to a burner is quite insufficient to make any appreciable difference in the temperature of the gas-flame. As a deduction from these experiments, the referees express an opinion that the advantages claimed for various materials used in the manufacture of burners are wholly imaginary, except that non-metallic substances are likely to be more enduring, inasmuch as they are not so liable to oxidation as metal.

As to the effects of cold upon the illuminating power of gas, it is reported that in the experiments made at Munich, when the U-tube was immersed in snow, so as to bring the temperature of the gas down to 32°, the illuminating power fell from 100 down to a point varying from 75 to 86; in other words, the light was reduced on the average to the extent of 20 per cent. And when the temperature of the gas was still further lowered, by using a mixture of salt and snow (temperature 4 below zero), the illuminating power was reduced by nearly one-third, ranging from 33 to 40, as against its full illuminating power of 100.

The latter temperature (− 4° F.) is one to which, in this country at least, gas as supplied to the public is never subjected; but as regards gas at the freezing-point (32° F.) and a little below it, the referees' experiments showed that this reduction of temperature made no difference in the illuminating power, gas at the freezing-point, and at a temperature of 296° F., being supplied alternately to the burner without making any difference in the readings of the photometer. At the same time it must be said that when gas is subjected to a freezing temperature for some time, a considerable decrease of its illuminating power will certainly occur; for in such a case a change will be produced in the constitution of the gas. Just as a very high heat alters the composition of gas, greatly diminishing its illuminating power; so will extreme cold from a kindred cause produce a similar result. In the former case, there is a disintegrating chemical effect produced by excessive heat, occasioning, *inter alia*, a deposit of carbon; in the latter there is the effect of freezing, by which the water contained in gas, in the form of aqueous vapour, is separated from the gas in the form of ice, and a portion of the illuminating hydro-carbons are condensed along with it.

It may be observed, as a matter of fact, that in street lamps (where the gas is fully exposed to the effects of temperature) there certainly is a marked diminution in the illuminating power during a severe frost. The experiments, however, were specially directed to determine whether a mere cooling of the gas (apart from the alteration of its constitution by the freezing of its aqueous vapour) produced any loss of light-giving power; and it was found that it did not,—the result of the experiments made by the referees entirely conflicting with that obtained in the laboratory at Munich.

Advantage was taken of the recent opening of the Chartered Gas Company's works at Beckton, to attempt to ascertain whether the distance of the point of manufacture from that of consumption had any effect upon the illuminating power, the gas produced at the Beckton works having to travel nearly nine miles to the Brick Lane station of the above company. This point is not yet definitively settled, but the present evidence tends to show that no appreciable injury occurs to the gas in its long passage. This is a very important question, and the answer given to it by further investigation will determine whether the existing legislation as to the position of the official testing-stations (namely, at 1000 yards from the gas-works) is adequate security for the interests of the public.

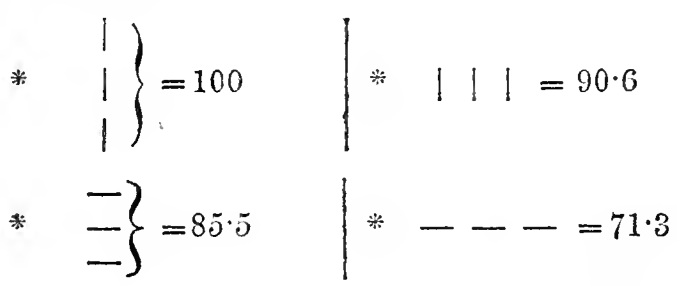
The last subject treated upon by the referees in this report, viz. the transparency of gas-flames to light, is one of considerable importance, bearing as it does upon the effective and economical arrangement of burners. If a gas-flame offers no obstruction to the light of other gas-flames or to a part of itself, then it matters not how the burners are placed or arranged; but if it does impede the transmission of light, then burners should not be arranged in such a manner that the light from one of them has to pass through that of the others,—or even through a part of itself, as happens when a batwing or fishtail burner is placed edgeways to the point of sight.

To determine this point,—namely, the transparency of gas-flames to the light of other such flames,—the following experiments were made in the laboratory of the referees:—

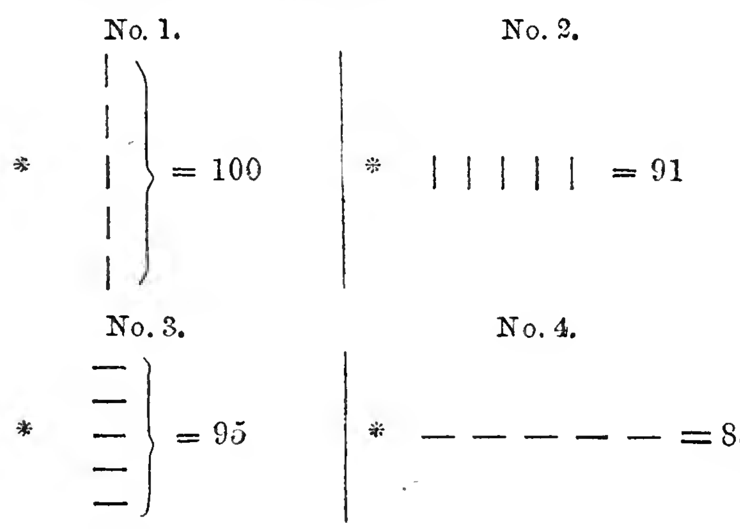
Three flat-flame burners (Sugg's No. 7 batwings) were fixed two inches apart on a stand, consisting of a piece of tubing, in such a manner as to allow the positions of the flames to be changed without altering the consumption of gas, and with the central burner always remaining at the same distance from the photometer disk.

The illuminating power was first determined by placing a stand at a right angle to the point of view (or to the photometer bar), and with the flat side of each flame exposed to the photometer disk, so as to allow the light from each burner to pass to the disk without any obstruction. The number thus obtained was taken as 100. The stand remaining in the same position as before, the burners were turned half round, so as to present the edge of the flame to the photometer. The illuminating power was again determined, and found to be only 85·5, showing a loss of 14·5 per cent. The stand was now placed in a line with the photometer bar, the flat side of the flames being exposed to the disk. In this position the illuminating power was 90·6, showing a loss of 9·4 per cent. The burners were then turned half round, bringing the flames in a line with the photometer-bar and edgeways to the disk. In this position the illuminating power was only 71·3, the loss being 28·7 per cent.

The following rough diagram will perhaps show, more clearly than a verbal description, the effect of the several arrangements of the gas-flames (marked —) upon the amount of light received from them on the photometric disk, marked *:—



A similar set of experiments were made, at Mr. Sugg's works, with five fishtail burners (Sugg's No. 6) placed $2\frac{1}{2}$ inches apart, the consumption of each burner being regulated, as in the previous experiment, to a uniform quantity by means of a separate governor. The results are shown in the following diagram:—



In this experiment the loss of light from obstruction appears less than in the former one, instead of greater, as it ought to have been when more burners were used. But, owing to the greater length of the stand upon which the burners were fixed (10 inches instead of 4), the light from the outer burners in the second experiment, when placed in a line at right angles to the photometer-bar, falls only indirectly on the disk; so that the illuminating power in position No. 1 ought to be reckoned higher than the actual reading of the photometer as given in the diagram. And in position No. 3 the illuminating power ought to be reckoned as lower, in consequence of the outer burners giving their light not really from the edge of the flames, but partly from their sides. Accordingly, although fewer burners were used in the first experiment than in the second, the photometric results obtained from the former may be regarded as more correct than those given by the latter.

From both of these experiments, however, it appears conclusively that gas-flames are not perfectly transparent, and considerably obstruct the light of other such flames placed behind them. Also, the loss of light by such obstruction was greatest when the flames were placed edgeways to the photometer, in which position the depth of flame through which the posterior light had to pass was greatest.

MEDICATED WATERS.

BY R. ROTHER.

This apparently unimportant subject has been under discussion by many commentators, especially those of Europe, and closer scrutiny of it reconciles the opinion that further study in its behalf is obviously justifiable. Most of the medicated waters, particularly the aromatic, were formerly directed to be prepared by distillation, and at the present day it is the only authorized method in most of the states of Continental Europe. The United States Dispensatory, in its comments upon the subject, sets forth the disadvantages of the method by distillation and the resulting products as compared to our simple and more expeditious officinal method, and the more satisfactory character of its results.

Yet, notwithstanding the superior elegance of the United States' officinal process, the use of magnesium carbonate for this purpose is open to a fatal objection, owing to the circumstance that magnesium carbonate is not insoluble in water. The Dispensatory states that the alkaline character of the water thus acquired decomposes the salts of morphia, mercury and silver by precipitating their insoluble bases, and that eventually a part of the magnesium carbonate itself separates.

By reason of the viscid flakes that separate from some medicated waters thus prepared, and the heavy crusts of magnesium carbonate which by time deposit from all, it is probable that either a portion of the magnesium hydrate, of which the officinal magnesium carbonate is largely composed, is first dissolved by the water and subsequently again precipitated as carbonate by absorption of carbonic acid, or that by the use of cold water a greater amount of magnesium carbonate is dissolved, which again deposits as the temperature of the water rises, or that the acidity of some oils which are not fresh causes the temporary solution of the magnesium compound. The object of the magnesium carbonate is to effect the solution of the volatile oil by presenting it in a finely divided condition to the utmost available action of the solvent. Other insoluble solids are occasionally employed to meet the same end, and the supposition prevails that such a procedure alone, aside from distillation, will ensure a saturated solution. The Dispensatory in this connection refers to the older method of the Dublin Pharmacopœia as being totally insufficient in comparison, since this consisted simply in agitating an alcoholic solution of the oil with water, whereby it is thought but a very feeble impregnation of the water is effected; and furthermore, that the minute quantity of alcohol thus introduced was objectionable *per se*, aside from the fact that it is liable, by the high degree of dilution, to pass into the acetous fermentation and render the water sour. However, no medicated water of any kind should be kept so long on hand as to become deteriorated by time; the simplicity of the modern processes admits of no apology for that.

The most perfect and convenient process by which the division of the volatile oil can be secured so as to expose the greatest possible surface to the contact of the solvent, is beyond dispute the method of precipitation, and this is performed by dissolving the oil in alcohol, and agitating the solution with a large volume of water. The requisite quantity of alcohol in any case need not exceed four times the volume of the oil; and although there exists a marked difference in the solubility of volatile oils in water, a solution of one minim in two fluid ounces of water can invariably be obtained; but frequently much more will dissolve, and therefore an excess of oil should always be used to make a saturated solution.

The writer's process for the aromatic waters, with the exception of camphor water, consists in using the officinal quantities of oil and water, together with four times as much alcohol as volatile oil. It is performed by dissolving the oil in the alcohol, and pouring this into an appropriately-sized bottle two-thirds full of distilled water. The mixture is now violently shaken for a few minutes, and the solution passed through a filter previously moistened with water.

The writer finds that the officinal quantity of camphor is much too great for the prescribed quantity of water. It is a grand mistake to assume that one pint of water dissolves fifty grains of camphor, which the Dispensatory distinctly states. The writer finds, by gradually adding an alcoholic solution of camphor to a measured quantity of water, that one fluid ounce of it, at the ordinary medium temperature, will dissolve nearly three-quarters of a grain of camphor, and that ice-cold water will dissolve nearly 20 per cent. more. The superior solvent power of cold water upon camphor can be very forcibly exhibited by agitating an excess of camphor previously dissolved in alcohol with ice-cold water, and filtering into a bottle until this is so full as to safely admit the insertion of a cork. The bottle is now securely closed and set aside. As the temperature of the water rises, the camphor begins to separate abundantly in shining crystals, which remain suspended until the water has reached the normal temperature, when, at the end of twelve hours, they will have mostly collected on the narrow surface of the liquid.

The writer makes camphor water by dissolving thirty grains of camphor in two fluid drachms of alcohol, pouring this solution into two pints of water, agitating for a few minutes in a bottle, as above directed, and filtering.

Chlorine water is a very unstable preparation. It should always be either fresh or quite recently prepared before use. But as the United States officinal process is not an extemporaneous one, and as the preparation is but rarely used in some localities, it becomes very difficult for pharmaceutists to furnish, at all times, chlorine water of the officinal strength.

Chlorine water rapidly deteriorates when exposed to light, or in partially filled bottles, by abstracting the hydrogen of the water and forming chlorhydric acid. An extemporaneous process would therefore be very desirable. A method of this kind is much in use, and, although the product may be equally efficient, it nevertheless is not by any means chlorine water in the officinal meaning of the term. In this process potassium chlorate is acted on by chlorhydric acid, and the deep yellow solution diluted with water; the result is mainly a solution of a mixture of the lower oxides of chlorine and probably free chlorine. The writer has long employed an extemporaneous process which yields a solution of pure chlorine, containing however sodium chloride, which is not an objectionable impurity. The method consists in the use of the officinal solution of chlorinated soda, chlorhydric acid and water. The officinal solution of chlorinated soda is a mixture of sodium hypochlorite, disodic carbonate and sodium chloride in aqueous solution. When brought in contact with chlorhydric acid, the sodium carbonate is first converted into sodium chloride with evolution of carbon dioxide, and, secondly, the sodium hypochlorite is decomposed into free chlorine and sodium chloride. The process is conducted by pouring into a quart bottle four fluid ounces of solution of chlorinated soda previously mixed with twelve fluid ounces of water, and then diluted chlorhydric acid by gradual addition, until, firstly, the carbon dioxide has been liberated and expelled; and, secondly, the available chlorine has all been set free and absorbed by the water, aided by frequent agitation. This product seems to be more permanent than the officinal article, as it retains the powerful odour of chlorine for a considerable time, even in bottles partially filled, if they are kept cool and excluded from the light.—*The Chicago Pharmacist.*

A NEW THEORY OF FERMENTATION.

BY A. PETIT.*

An attentive study of the phenomena of fermentation has led the author to propose a new theory, based on the following facts:—

1. Ferment globules may be produced without fermentation.

2. Fermentation may take place, as has also been shown by Berthelot, in the absence of ferment globules.

3. In a filtered fermentable liquid, globules form without inducing fermentation. It commences only when a certain number of globules are deposited at the bottom of the vessel, the bubbles of carbonic anhydride then proceeding exclusively from the bottom.

4. Fermentation is retarded, and even stopped, when the sugar is in very dilute solution.

5. By augmenting the relative proportion of ferment, the resistance which certain anti-fermentescible substances, creasote, sublimate, organic and mineral acids, oppose to fermentation may be overcome.

6. When the proportions of ferment and sugar are suitable, fermentation commences instantaneously.

7. By varying the sugar within very wide limits (from 20 to 300 grms. per litre in the author's experiments), the volume of gas disengaged is the same for the same quantity of ferment.

8. After a certain time, necessary to attain a maximum, the quantity of gas disengaged is exactly proportional to the time.

9. Sulphites do not prevent fermentation; they are converted into sulphates.

10. Beer-yeast suspended in water absorbs a certain quantity of iodine, converting it into hydriodic acid. This liquid saturated with iodine can, after fermenting some time, again absorb a further quantity. In presence of yeast, water is thus decomposed, the hydrogen uniting with the iodine, the oxygen with the globules. This property of the globules of absorbing oxygen has, moreover, been thoroughly established in the case of the blood-corpuscles and the acetous ferment.

On these observations the following theory is founded. The sugar being dissolved in water in presence of yeast, water becomes decomposed, and hydrogen and oxygen are set free. The oxygen enters, momentarily at least, into combination with the substance of the globules; the hydrogen in the nascent state attaches itself to a molecule of sugar, and causes its decomposition, the products being alcohol, carbonic anhydride, and one equivalent of hydrogen, which decomposes a further molecule of sugar, and so the reaction proceeds:—

$$C_6H_{12}O_6 + H = 2\,C_2H_6O + 2\,CO_2 + H.$$

A single molecule of hydrogen should theoretically decompose an indefinite quantity of sugar, were it not that secondary reactions occur, the principal of which consists in the formation of glycerin:—

$$C_6H_{12}O_6 + 4\,H = 2\,C_3H_8O_3.$$

The author was led to consider the hydrogen the prime agent—although the oxygen may equally well be so regarded, and nothing proves that under certain con-

* Compt. Rend. lxxiii. 267–270, from the *Journal of the Chemical Society.*

ditions of experiment it is not so—by the fact that on allowing two similar liquids to ferment, but with the addition of 1 per cent. of sodium sulphite to the one, the same disengagement of carbonic anhydride took place in both cases, although the oxygen had served to convert the sulphite into sulphate. In this experiment no acids were formed.

If the fermentation takes place in the absence of sulphites, the oxygen forms succinic and acetic acids.

CARBOLIC ACID IN THE POWDER FORM.

Professor C. O. Curtman, in a communication to the *American Journal of Pharmacy*, refers to the inconvenience sometimes arising from the corrosive action of concentrated solutions of crude carbolic acid, and says that a preparation in which a dry argillaceous powder is used instead of water as a diluent of the acid, has some very decided advantages over the common solutions. The powder as used by him is quite dry, has very little coherence, is light and porous, little inclined to form lumps by exposure to moisture, and contains about 20 per cent. of the mixed tar acids, which gradually and slowly volatilize when the powder is exposed to the air.

In order to ascertain whether the corrosive qualities of the acid were modified without sacrificing any valuable quality, Professor Curtman made some experiments upon a number of shrubs and flowers in his garden which had become infested by swarms of various parasites. Selecting a rose-bush upon which thousands of green insects were preying, he attempted to destroy them by syringing the plant with a quarter per cent. solution of crude carbolic acid. The experiment was unsuccessful until the solution had been increased in strength to four per cent., when some of the insects died, but the rose-bush also began to wither, and after a few weeks of sickly existence perished. Similar results were obtained in other experiments.

The powder containing about twenty per cent. of the acid was next sprinkled slightly over different plants. On the first day neither plants nor insects appeared to be affected, but after three days very few parasites remained on the plants, while no damage whatever had occurred to the plants.

Professor Curtman considers that in the use of carbolic acid the continuous and regular exhalation of the acid vapour from the finely divided surface of the powder is preferable to its more irregular diffusion resulting from the evaporation of an aqueous solution, and that in inexperienced hands the pulverulent preparation is much safer than solution in liquids. He recommends clay as preferable to other substances for this purpose, on account of its entering into no combination with the acid, but acting simply as a neutral, inert, mechanical diluent.

SYRUPUS ASSAFŒTIDÆ COMPOSITUS.

In the *American Journal of Pharmacy*, Mr. J. J. Rambo publishes a formula that he has for a number of years been in the habit of preparing, to obviate the great objection felt by most patients to the disagreeable smell and taste of assafœtida, which has prevented to a great extent the more general use of this valuable drug. The formula he has found to answer the purpose effectually, at the same time he considers that its medicinal qualities are enhanced by combination with syrup of wild cherry, thus presenting the valuable therapeutic properties of both.

℞ Infusi Pruni Virginianæ Oj
Assafœtidæ ℥j
Sacch. Albi ℥xxiv
Magnes. Carb. ℥ij.

Rub the assafœtida and magnesia, with the infusion gradually added so as to make a uniform mixture, and filter; to this, transferred to a bottle, add the sugar, and agitate occasionally until it is dissolved. The result is a handsome syrup, which does not differ in appearance from the syrup of wild cherry.

The property possessed by the volatile oils of bitter almonds, cherry-laurel leaves, bark of wild cherry, etc., containing hydrocyanic acid, of removing the odour of assafœtida has long been known, and advantage taken of this property by M. Maheir, a French pharmaceutist, to remove the odour from mortars and bottles with which it came in contact; but Mr. Rambo is unaware that the fact has ever been applied to its administration as a medicinal agent.

PRESENTATION OF A TESTIMONIAL TO A PHARMACEUTICAL CHEMIST.

On Thursday, September 9th, a very interesting ceremonial took place, in the Town Hall, at Reading, on the occasion of the presentation of a very handsome testimonial to Mr. Peter Spokes, Pharmaceutical Chemist, the late mayor. It consisted of a chaste dessert-service and silver inkstand. The dessert-service comprised a very handsome epergne, or centre-piece, twenty-one inches high, with a tripod-panelled base, with vine leaves and grapes, twisted vine-stem and trellis-basket supporting a rich cut-glass bowl. The figures on base are two boys sporting with a goat. The four dessert-stands to match, are $13\frac{1}{2}$ inches high, with figures representing the four seasons, viz. Spring, girl and lamb; Summer, boy feeding hen and chickens; Autumn, girl and goat; Winter, shepherd boy and dog. Each piece bears the following inscription:—"Presented to Sir Peter Spokes, Knight, Mayor of Reading, November 9th, 1871, by his fellow-townsmen, as a token of their respect, and of their cordial approval of the efficient manner in which he has discharged the duties of the Mayoralty during two successive years, 1869–70, 1870–71." The inkstand is 12 inches long, of Elizabethan style, with two cut-glass inks; hexagon wafer-box in centre, surmounted by a figure of "Justice," with scales, richly engraved in the style of the period. The inkstand bears the following inscription:—"Presented, together with a silver dessert-service, to Sir Peter Spokes, Knight, Mayor of Reading, November 9th, 1871, by his fellow-townsmen, as a token of their respect and of their cordial approval of the efficient manner in which he has discharged the duties of the Mayoralty during two successive years, 1869–70, 1870–1871."

The testimonial was presented by the Rev. A. P. Perry-Cust, who said that, although he differed from Mr. Spokes in religious and political opinions, he was happy to be able to bear his testimony to the able manner in which Mr. Spokes had fulfilled the duties of his office, especially on the occasions of the installation of a new High Steward of the borough and the laying of the first stone of the new grammar-school by the Prince of Wales. He also congratulated him that upon his retirement from the mayoralty, he carried with him the stamp of her Majesty's approval in the offer of knighthood that had been made to him.

Mr. Spokes returned thanks in a feeling and eloquent speech.

Mr. Shaw-Lefevre, M.P., also congratulated Mr. Spokes upon the success with which he had performed the duties of Mayor for the last two years. He said that he had seen the letter written by the Prince of Wales to Mr. Gladstone, asking him to advise her Majesty to confer the honour of knighthood upon Mr. Spokes, and that it referred in high terms to the enthusiasm and loyalty with which the Prince was recently received at Reading.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 18, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE DUTY ON CHLORAL HYDRATE.

THE consumption of chloral hydrate bids fair to be as fruitful a topic for the sensational writers at this dull season of the year as was the case of strychnine in 1850, when the statement was made in a French newspaper that M. Payen in one of his lectures had said that much of the strychnine made in Paris was sent to England for the manufacture of bitter beer. To this day many people are credulous enough to believe this nonsense, and would be offended with those who differed from them in opinion on this subject. Now, up to the present time no satisfactory proof whatever has been adduced that chloral has been ever used in beer; and, however attractive sensational articles and letters may make the newspapers containing them, it is not fair either to the brewers of beer or to the public that such liberties should be taken with our national beverage.

To those who constantly have to analyse beer, such wild statements are known to be untrue; and it may be broadly stated, without fear of contradiction, that beer is seldom adulterated with hurtful materials, but the adulteration generally consists in diluting with weaker beer or with sugar and water, in order that the beer sold may yield a larger margin of profit than would otherwise be obtained. We are not advocates even of harmless dilution, but condemn sophistication in every shape and form, and hope the day is not distant when by legislative enactments the Government will undertake the responsibility of suppressing the adulteration of food, drink and drugs.

Although no reliable statistics can be given, we believe that both the quantity of chloral hydrate imported and its consumption in this country have been very much over-estimated, and we may be quite sure that the Customs duty now imposed upon it of 1*s.* 3*d.* a pound will decrease the consumption, and also divert the manufacture from Germany to England. The absence of competition will probably tend to increase the price; and if the price be increased, it may in the end prove a means of causing the chloral to be used in a more legitimate manner than it otherwise would be.

The mention of the imposition of this duty brings us at once to the real subject-matter of this article, which is, why was this duty imposed? From inquiries we have made on the subject, and from the clause in the Act imposing the said duty, the facts appear to be these. A certain amount of alcohol has to be used in the preparation of the chloral hydrate, the chloral is therefore chargeable with a duty "equivalent to that which is chargeable on the like quantity of spirit on its importation." The duty on alcohol imported is 10*s.* 5*d.* per gallon at proof strength, and as a gallon of such spirits weighs $9\frac{2}{10}$ lb., it follows that according to the duty imposed it has been found that $1\frac{1}{10}$ lb. of proof spirit is required to produce 1 lb. of chloral.

The very heavy duty on alcohol in this country—which produces an annual revenue of not less than fifteen millions per annum—has a tendency to restrict all manufactures in which alcohol is used, and it is only by countervailing duties levied on similar articles imported from abroad, that our manufacturers are able to hold their own even in this country. It is true that the Methylated Spirit Acts have set free many branches of industry in this country which otherwise could never have been successfully carried on, but these remarks only apply to the manufacture of such goods as are not deteriorated by the offensive odour of methylated spirit.

In pharmacy methylated spirit ought never to be used; and, to the honour of those who were consulted on behalf of the Pharmaceutical Society, it is recorded that they were strongly opposed to allowing methylated spirit to be used in the preparation of medicine of any kind. It is well known that the first of the methylated spirit Acts were grossly abused, and that the preparation from methylated spirit of medicines for internal use was so common, and found to be such an extensive fraud on the Revenue, that eventually legislative action had to be taken in the matter, and it was made illegal to prepare medicines for internal use from methylated spirit. In this Act, however, exception was made to chloroform and ether, on the ground that these substances, when properly prepared, would not contain alcohol of any kind. But we know from experiment that there is little difficulty in determining whether a sample of chloroform or ether is made from pure alcohol or methylated spirit, and this fact at once shows the difficulty there is in practice in getting rid of the offensive hydrocarbons and other impurities which are always present in methylated spirit. Doubtless if chloral had then occupied as prominent a place in public estimation as it does now, it would also have been put in the same category as ether and chloroform, and when prepared from methylated spirit it would, no doubt, as easily betray its origin when submitted to chemical treatment as do the other two substances named.

As before stated, the heavy duty on chloral will probably tend to check its general use, but, however objectionable this may be, our home manufacturers have cause for congratulation that their interests are protected, although the general body of pharmaceutists will have to suffer for the change in the law by having to pay a higher price for their goods, and will also in many instances have imposed on them methylated chloral for the genuine article, as the difference in price will be a strong inducement to unprincipled manufacturers to substitute the cheap for the dearer kind.

In studying this question, there appears to be but one way of getting rid of the duties on such necessary preparations as chloral, chloroform and other substances that cannot be prepared without alcohol, which is, that these goods, when manufactured in this country, should be made in bond from duty-free spirit. Many difficulties surround the subject, and we are not prepared to speak confidently of the practicability of this suggestion, knowing the subject is such a wide one. If it were granted by the Treasury, the Customs authorities would, in order to protect the spirit revenue, certainly have to impose stringent regulations on those manufacturers who availed themselves of the privilege. Still, the concession would be the means of increasing honest competition, which always proves to be of great benefit to the public, and it would also give our manufacturers opportunities of making original experiments with duty-free spirit, which they cannot now afford to do with that which is duty paid.

THE APPLICATION OF THE PHARMACY ACT.

A short time since we called attention to the fact that under the Pharmacy Act, 1868, any one has the power of proceeding against persons who deal illegally in poisons, and we suggested that if those who are injured by such illegal dealing would study the provisions of the Act, they would see how easily they could protect themselves by its aid. But our remarks have received a rough commentary in a case reported in another part of this Journal; and if the decision of the magistrates,—who appeared on this occasion to understand the provisions of the Act,—is to be taken as a specimen of what will be done in similar cases, the Pharmacy Act, so far as the sale of poisons is concerned, will become a dead letter. In this case a sale of oxalic acid insufficiently labelled was proved, and admitted by the defendant, and very properly a fine was inflicted for the offence; but we are utterly at a loss to conceive why the complainant should have had to pay the costs; the penalty thus practically falling upon him. If it come to be understood that in addition to the trouble, those who endeavour to perform a public duty are to be put to considerable expense, we fear that the sale of poison will go on without any attempt to enforce the present legal restrictions.

It is curious, in the presence of such difficulty in carrying out what is now the law of the land, to meet with so much vague declamation as to the duties of pharmaceutists in regard to the sale of poisons. An addition to the many published instances of it from persons who might have been expected to be better informed, will be found the following quotation from a paper by Dr. John Spencer Ferris, of Uxbridge, in the *British Medical Journal*, concerning some anomalous symptoms in a case of morphia poisoning, where he says:—

"The twenty-five drops of morphia were dropped out of a four-ounce bottle, labelled 'Solution of Muriate of Morphia, ten to sixty drops per dose,' obtained from a chemist in Reading, so that I cannot exactly tell the strength, more especially as these were almost the last drops in the bottle, and very probably there was some undissolved alkaloid in them. How is it a chemist, now that the Pharmacy Act has come into operation, dares to sell to an unprofessional person four ounces of morphia solution?"

The writer's difficulty as to the strength of the solution betrays an ignorance of the Pharmacopœia that is balanced by his ignorance of a pharmaceutist's duty under the Pharmacy Act.

Another illustration of the incorrect ideas upon this subject, current even among those connected with pharmacy, has recently come under our notice. Upon a gentleman who is in business, but not on the Register of Chemists and Druggists, being informed that he must take steps to place himself upon the Register if he purposed to continue in business, he replied, that he had been registered many years since, when he had taken up his freedom of the City of London, and that proof of his statement might be seen at the Chamberlain's office.

MUNICIPAL HONOURS TO PHARMACEUTISTS.

We record in another column a very interesting ceremonial, the object of which was to do honour to a pharmaceutist, and one of the Local Secretaries of the Pharmaceutical Society, in the person of Mr. Peter Spokes,—or, as he now is virtually, and by the exercise of her Majesty's prerogative soon will be actually, Sir Peter Spokes,—of Reading. In addition to this gratifying testimony to the municipal worth of a member of the pharmaceutical body, we are enabled to state that the following gentlemen were recently elected to the mayoralty of their respective towns:—Mr. E. Bagott, Chemist and Druggist, Dudley; Mr. T. Deighton, Pharmaceutical Chemist and Local Secretary, Bridgnorth; Mr. John Irving, Chemist and Druggist, Carlisle; Mr. Robert Payne, Chemist and Druggist, Wallingford; Mr. John Slater, Chemist and Druggist, Beaumaris; Mr. Robert Walker, Pharmaceutical Chemist and Local Secretary, Maidenhead.

In the opening columns of our Journal this week will be found an article on the question, "Shall the Pharmaceutical Society Cease to be an Educating Body?" which we recommend to the careful attention of our readers, as illustrating the views held in some quarters upon the subject. At the same time we would suggest that members who have thought upon the question and hold decided opinions concerning it, should communicate them, in order that the topic should be discussed with the fulness that is due to its importance.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

November 15th, 1871.

Present—Messrs. Allchin, Barnes, Bird, Carteighe, Cracknell, Davenport,*Edwards, Gale, Garle, Haselden, Ince, Linford and Southall.

MAJOR EXAMINATION.

Three candidates were examined; *one* failed, the following *two* passed, and were declared duly qualified to be registered as

PHARMACEUTICAL CHEMISTS.

*Hughes, James..............Swansea.
Peters, David ....Llandilo.

MINOR EXAMINATION.

Thirty-two candidates presented themselves; *ten* failed, the following *twenty-two* passed, and were declared duly qualified to be registered as

CHEMISTS AND DRUGGISTS.

*Hanbury, Frederick Janson ..London.
*Druce, George Claridge ......Northampton.
*Hyne, Harry ....Bristol.
Equal { *Breckon, Hugh Scott........Whitby.
Equal { *Woolldridge, George ....Birmingham.
Herbert, John..............Kingston-on-Thames.
Hooper, William ....Croydon.
Ormond, Richard ....Pembroke.
Salter, Thomas ....Bradninch.
Hicks, William Thomas ......Ipswich.
Laugher, William ....West Bromwich.
Mason, Jonathan ....Workington.
Bright, John Valentine ......Bath.
Warner, George Henry Quibell March.
Jessop, John Arthur ....Willenhall.
Squirrell, John Newton ......Manchester.
Jones, Owen ....Llangefni.
Squire, Thomas ....Great Torrington.
Davison, John ....West Hartlepool.
Bennett, John Henry ....Cheltenham.
Walsh, Albert ....Richmond.
Greasley, John..............Borrowash.

The above names are arranged in order of merit.

PRELIMINARY EXAMINATION.

Certificates were received from the undermentioned in lieu of this Examination:—

Luff, Arthur Pearson ....Old Brompton.
(Certificate of College of Preceptors.)
Trubshaw, Charles ....Dudley.
(Certificate of the University of Cambridge.)

* Passed with honours.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Second General Meeting of this Society was held on October 26th; the President Mr. E. Davies, F.C.S., in the chair.

Messrs. John Sumner, Frederick Pott and Henry Huskisson de Witte were elected members, and Mr. James Walmsley Hargreaves was elected Associate of the Association.

The following donations were announced:—current numbers of the Pharmaceutical Journal, the New York Druggists' Circular, the Journal of the Polytechnic Society, and a Reprint of Notes on Pharmaceutical Preparations, by Mr. J. Abraham.

Mr. Thomas Williams read a paper "Upon the Manufacture of Alum and its Applications."

The President mentioned the recent formation of coniine artificially, as a remarkable fact, as it was the first vegetable alkaloid which had been so formed. He now entertained more hope that quinine and morphine might be so produced than he did formerly.

Mr. A. E. Tanner said he had always been of the opinion that all the alkaloids would at some future day be artificially produced, and thought that the President had placed too great a limit on the future of chemistry. Mr. Tanner also referring to the subject of the paper which had been read, observed that all samples of alum contained some iron, and instanced the change of colour produced on adding this salt to infusion of roses; an annoyance most pharmacists had experienced.

Mr. Williams explained that pure alum would not certainly affect the colour of the infusion.

A vote of thanks to Mr. Williams for his interesting paper was proposed and carried unanimously.

HULL CHEMISTS' ASSOCIATION.

At the opening of the Session of the School of Pharmacy in connection with the Hull Chemists' Association, on the 26th October, the President, Mr. A. Pickering, delivered the following address to the students:—

Gentlemen,—In commencing the duties of my office as President of the Hull Chemists' Association, to which I have so recently been elected, I think I cannot do better than address a few words of encouragement to the young students I see before me, at the opening of another Session of its School of Pharmacy.

It is now between thirty and forty years since I first entered the trade, and I rejoice to tell you that pharmacy has made considerable progress during that time. Many new and valuable remedies have been added to the Pharmacopœia, and will for ever retain a place there; the morphias and other preparations of opium, quinine and the other preparations of bark; many new preparations of mercury, chloroform, chloral, methylic ether, carbolic acid, cod-liver oil and many others too numerous to mention, but all of them invaluable in the hands of the medical practitioner for the alleviation of human suffering. This list appears likely to be largely increased every year, from the increasing study of the active principles of plants and the state of combination in which they exist in them.

Chemistry, too, is busy forming new compounds not found in nature, and in ransacking and reducing the mineral kingdom for the service of man. Chemistry has made gigantic strides during the last thirty years. Look at the beautiful art of photography with its long list of chemical preparations; see how the oils and fats have been utilized in the forms of soap and candles; how the bowels of the earth have been made to yield their petroleum and paraffin; how coprolites and bones and the sewage of large towns are all, by the magic wand of chemistry, transformed into manures invaluable to the agriculturist. Look at aniline and the other new preparations used in dyeing; at those wonderful flavouring essences so cunningly formed as to give to liquors and sweets the flavour of the raspberry, strawberry, pine-apple and every description of fruit. What valuable new disinfecting agents are now prepared for destroying malaria, contagion and arresting the progress of epidemics; for deodorizing the refuse of towns and rendering them more healthful! It is my own opinion that there is not a disease for which Divine Providence has not provided a remedy, and which will certainly be discovered if we diligently search for it; that there is not anything in creation but will at some time or other be rendered subservient to the use of mankind, and that the great agent which will be employed for that purpose will be chemistry.

The School of Pharmacy has been established for the special benefit of the rising generation of pharmacists. Your lines have fallen to you in pleasant places. Your lot is very different from those who entered the profession thirty or forty years ago. When I first went as an apprentice we commenced the duties of the day at six o'clock in the morning by taking down the shutters, and had the privilege of putting them up at nine o'clock in the evening, and of finally closing the door at ten o'clock. After sixteen hours of labour, I need not tell you, we were truly thankful to fall into the arms of Morpheus. At that time of day all drugs were powdered by mortar and pestle, peppers ground in a hand-mill and paints on a slab with a muller. Quicksilver we used to kill by means of "elbow grease," *by rubbing in a mortar for three weeks together*. The hours of labour were not lessened when I became a retail assistant in London. There we commenced the duties of the day every six out of seven, by going into the shop at seven o'clock in the morning and never leaving it until half-past eleven o'clock at night. This will give you some idea of the few opportunities the old generation of pharmacists had of obtaining a scientific knowledge of their business.

Schools of pharmacy there were none. The only lectures at all bearing on the subject were those delivered at the Medical Schools in London. Most of those whose names have been eminent in pharmacy during the past generation, laid the foundation of their knowledge and their success in life by availing themselves of those lectures. But very few members of the trade were able to do so.

Here, in Hull, you have the means of obtaining a thorough knowledge of your profession. You have the advantage of an exceedingly able lecturer, and everything necessary to illustrate his lectures. Give to him your undivided attention whilst you are here; devote your leisure hours to the study of those subjects on which he lectures. Give your minds and imaginations no time to run riot, thus shall your paths be kept from evil and a glorious future of a useful career await you.

I trust I have done something in my time by example to shorten the hours of toil. So exhausted was I when I left the retail situation in London, that for twelve months I was unable to do anything. Exhausted in body and mind by such excessive toil, I determined, when I commenced business for myself that no one should ever, in my employment, work the same number of hours which I had done. I consider myself the pioneer of early closing in Hull. Ever since I have been in business, have I closed my shop at eight o'clock in the evening, when there was not another in the town that did. I do not mean to say that I do not supply medicines after that hour, but I do not court trade after that hour at the expense of the health, happiness and social comfort of those around me.

There is one other subject I should wish to say a few words on before I sit down. I shall probably never live to see it, but I trust most of you will, when the practice of pharmacy will be entirely separated from the practice of medicine; when there will be a broad line of demarcation between the two branches of the profession; when there will be no longer surgeons keeping open druggist shops and surgeries, as so many do in London; when there will be no more prescribing druggists; when each will confine themselves to their respective branches of the profession; when each branch will unite together only for the purpose of discovering new remedies for the treatment and cure of disease and suffering. Probably ninety parts out of every hundred of the medicine used in this country is sent out of the surgeries of medical practitioners and the dispensaries, infirmaries and other public institutions. This compels the great majority of the chemists and druggists of this kingdom to deal in a multiplicity of articles which are not drugs, but this they are compelled to do or to starve. I cannot help thinking that if the two branches of the profession were entirely separated, and there were only prescribers and dispensers, they would both be great gainers in social standing.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

On Thursday evening, November 2nd, Mr. Woodward, B.Sc., of the Birmingham and Midland Institute, gave the first of a series of special lectures on the "Chemistry of the British Pharmacopœia" to the students attending the classes lately formed in connection with the Midland Counties Chemists' Association. These lectures are given on the first Thursday in the month, and are in addition to the usual chemistry lectures every Tuesday evening.

Mr. Woodward has not only thrown them open to members of the Midland Counties Association attending the chemistry classes, but also to those attending the Latin and botany classes. It is hoped, therefore, that there will be a good attendance of those for whom the lectures are intended.

NORWICH CHEMISTS' ASSISTANTS' ASSOCIATION.

The following arrangements of classes have been made for the winter session:—

On successive Mondays, Botany, by Mr. P. H. Mason; Materia Medica, Mr. A. J. Caley; Galenicals of the British Pharmacopœia, Mr. J. Goodenough.

On Wednesdays, Chemistry of the British Pharmacopœia, by Mr. E. Nuthall.

It is also intended that three prizes shall be awarded, at the close of the winter session, to those students who shall have made greatest progress in their studies, the test for which will be a *vivâ voce* examination, to be held in April, 1872. The subjects comprised will be those required for the "Minor Examination" (with the exception of practical dispensing).

Those students only will be eligible to compete who shall have attended at least two-thirds of the winter classes.

Mr. A. J. Caley, before entering upon the subjects in which he had undertaken to instruct the members of the materia-medica class, gave the students a short but encouraging address, in which he urged the necessity of real study, and pointed out that the examinations of the Pharmaceutical Society were not to be so easily passed as some of the students appeared to imagine.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

Dyes and Dye-Stuffs other than Aniline.*

BY DR. CRACE-CALVERT, F.R.S.

Lecture I.

Red Colouring Substances.—Madder.

(*Continued from page* 396.)

Pure alizarine sublimes, at a temperature of 460° F., into pale orange prismatic crystals. When slowly crystallized from an ethereal solution, it forms a hydrate, containing two equivalents of water, which crystallizes in lustrous scales. Cold water dissolves a mere trace of alizarine, but its solvent power increases as the tempera-

* Cantor Lecture, delivered Tuesday, Feb. 7. Reprinted from the *Journal of the Society of Arts*.

ture is raised, as may be seen from the following figures:—

At 212° 100 parts of water dissolve . . . . ·034
At 400° 100 parts of water dissolve . . . . ·820
At 480° 100 parts of water dissolve . . . . 3·160

Alizarine is freely soluble in alcohol, ether, wood spirit, benzole, turpentine, sulphuret of carbon, and glycerine. It is soluble without decomposition in sulphuric acid, even at a temperature of 400° F., and is thrown down unchanged when large quantities of water are added. It is soluble in a warm solution of alum, but insoluble in a cold one. It has been assigned different formulæ by different chemists, the two most generally adopted being that of Dr. Schunck, $C_{14}H_{10}O_4$, and that of Wolf and Strecker, $C_{20}H_{12}O_6$. Alizarine gives a purple colour with a weak solution of caustic alkali, which undergoes no change by the action of air. It yields, with alumina fixed in fabrics, a variety of red and pink shades; with oxide of iron it gives purples and blacks; and, with a mixture of these two oxides, chocolates.

I shall now call your attention to one of the most interesting and important discoveries of chemistry, as applied to manufactures, which have been made of late years, namely, the artificial production of this most important colour-giving principle, alizarine, or of a substance which, if not identical with, has great similarity to it. Messrs. Graebe and Liebermann, and Mr. Perkins, believe in the identity of the artificial product with the natural one. But this is denied by M. Alfraise, on the grounds, first, that the formula given by Messrs. Graebe and Liebermann does not agree with that given by Dr. Schunck, as is shown by the following figures:—

Schunck.	Graebe and Liebermann.
$C_{14}H_{10}O_4$	$C_{14}H_8O_4$

Secondly, that the artificial alizarine does not give the same coloured sublimate as the natural alizarine; and thirdly, that if both these substances are acted on by nitric acid, natural alizarine is converted into phthalic acid, whilst the artificial alizarine, which he calls alizapurine, yields a large quantity of a nitro-compound having an intensely bitter taste, mixed with only a mere trace of phthalic acid. These observations of M. Alfraise have been confirmed by M. Kopp. That the commercial artificial alizarine is not identical with a natural alizarine is rendered still more certain by the researches of Dr. Schunck, who, on examining a sample obtained from Mr. Perkins, found it to contain a large quantity of a compound crystallizing in yellow, silky needles, anthraflavic acid, and which he obtained by treating Mr. Perkins's product with alcohol. On treating the acid with fuming nitric acid he obtained a nitro-compound, the potash salt of which he describes as resembling picrate of potash. This is doubtless the bitter principle which Alfraise obtained, but did not study. Dr. Schunck gives the formula of anthraflavic acid as $C_{15}H_{12}O_4$, and considers it homologous to alizarine, one equivalent of its hydrogen being replaced by methyl. Messrs. Graebe and Liebermann, and Mr. Perkins, found their opinion as to the identity of the two alizarines, on the fact that they give the same absorption bands on being submitted to Professor Stokes's spectrum test.

Artificial alizarine was first made, in 1869, by Messrs. Graebe and Liebermann. The substance from which they obtain it is *Anthracene*, a body discovered by Professor Anderson, of Glasgow. Anthracene is one of the last products passing over in the dry distillation of coal-tar, and is found most abundantly in the 10 or 15 per cent. which comes over from the temperature where soft pitch is formed, and that where hard pitch is produced. The quantity of anthracene in coal-tar varies greatly; it is most abundant in the tars obtained from those coals which yield most naphtha. The South Staffordshire coals give the largest quantity, whilst the Newcastle coals give very little. Its extraction can only be carried on with advantage in cold weather, as it becomes very soluble on a slight rise of temperature in the oily homologues which accompany it. At a temperature of about 40°, the distillate above described is semi-fluid; it is placed in a hydro-extractor, and the oily fluid separates from the solid matter, which is then submitted to cold and hot pressure. The cake thus formed is pulverized and carefully washed with petroleum spirit, having a boiling-point of about 180°, which leaves anthracene moderately pure. This powder dissolved in alcohol and crystallized, yields anthracene in nearly white scaly crystals, or in a fit state for the manufacture of artificial alizarine.

Messrs. Graebe and Liebermann oxidized the anthracene ($C_{14}H_{10}$), by nitric acid, into anthrachinon ($C_{14}H_8O_2$), this being again converted into bibrom anthrachinon ($C_{14}H_6Br_2O_2$), which by fusion with potash is changed into alizarine ($C_{14}H_8O_4$). There are three patents published, and a process, the details of which are kept secret. It is curious to notice that the patent taken out by the above-named gentlemen and Mr. Caro is dated the 25th of June, 1870, while Mr. Perkins entered his on the day following, in which nearly the same processes are described, merely employing different oxidizing agents.

The following is an outline of one of the processes detailed in the specification of Messrs. Caro, Graebe and Liebermann:—One part of anthracene is heated with four of sulphuric acid, of sp. gr. 1·845, for three or four hours, to a temperature of 212° F., and then for an hour at 300°. The mixture is allowed to cool, and to it is added water equal to three times the weight of anthracene taken, and manganese equal to four times that weight. The whole is boiled for three hours, and milk of lime is then added, which gives rise to a deposit consisting of the excess of lime and manganese used, and protoxide of manganese, while there remains in solution a double sulphate of anthrachinon and lime. This solution is now acted on by carbonate of soda in slight excess, carbonate of lime separates, and the salt of soda thus produced is evaporated to dryness. To this solid mass are then added two or three parts of caustic potash or soda and a small quantity of water, and the whole heated under pressure, in suitable vessels, at a temperature of 350° to 500° for one hour, when the anthrachinon is further oxidized and converted into alizarine. Thus anthracene, $C_{14}H_{10}$, gives anthrachinon, $C_{14}H_8O_2$, and this alizarine, $C_{14}H_8O_4$. The alkaline mass, on cooling, is dissolved in water, and sulphuric or acetic acid added in slight excess, when an orange-yellow flocculent substance precipitates, which, when properly washed and dried, is artificial alizarine.

The second colour-giving principle of madder, to which I have referred several times already, is called purpurine, and was also discovered by MM. Robiquet and Colin, in 1828. Although in commerce it is sold as a red powder, as has been mentioned above, still, by heating at a temperature of 480° F., it can be obtained in the form of feathery crystals, of an orange-red colour. It is more soluble in water than alizarine, especially at a temperature of 140° F., and is also soluble in the menstrua already mentioned under alizarine. Further, it gives a red colour with caustic alkali, instead of purple as alizarine. It is soluble in a cold solution of alum, while alizarine is not. When fixed on fabrics, its colours do not stand exposure to light as well as those of alizarine.

Professor Stokes, of Cambridge, has found a most elegant method of discovering and characterizing mere traces of these colouring principles. So delicate is the test, that the colouring matter on one square inch of dyed fabric is sufficient to obtain the results. He treats the fabric with a solution of carbonate of soda, which dissolves the colouring matter. The solution is then introduced into a small tube, which is placed before a slit in the shutter of a dark room. The light which passes through is decomposed by a prism, when a spectrum is produced. The operator will observe that, when purpurine is taken, there are principally two black bands formed by the absorption of light in the green part of the spectrum, having between them a band of green light; whilst alizarine exhibits, on analysis, a band of absorption in the yellow, and another narrower one between the red and the orange.

Professor Schützenberger, by treating commercial purpurine successively with alcohol and benzine, unfolded it into four different substances, to which he assigns the following formulæ:—

	Alizarine	$C_{20}H_{12}O_6$.
1.	Purpuroxanthine .	$C_{20}H_{12}O_6$ or $C_{20}H_{14}O_6$.
2.	Purpurine . . .	$C_{20}H_{12}O_7$ or oxy-alizarine.
3.	Orange matter . .	$C_{20}H_{16}O_9$ or hydrate of purpurine.
4.	Pseudopurpurine .	$C_{20}H_{12}O_9$ or oxy-purpurine.

I shall now call your attention to a very remarkable discovery, recently made by the late Professor Bolley, viz. the conversion of purpurine into alizarine. If purpurine is heated in the atmosphere, as stated above, it is nearly all sublimed, leaving only a small amount of carbonaceous residue, but if heated in sealed tubes, at a temperature of 400°, it forms a carbonaceous mass from which water extracts alizarine. Under the influence of the high temperature, the purpurine loses an equivalent of oxygen, and is converted into alizarine. This reaction appears to confirm the opinion of M. Decaisne, that the madder plant contains only one colour-giving principle, which under the oxidizing influence of the atmosphere becomes converted, first, into alizarine, then purpurine, and afterwards into the still more highly oxidized compounds.

The difficulty and expense experienced by calico-printers in brightening their colours and obtaining pure whites in madder-dyed goods, attracted many years ago the attention of scientific and practical men, and any process by which these difficulties might be overcome was anxiously looked for. The discovery of MM. Robiquet and Collins, that the colour-giving principle was not destroyed by sulphuric acid, was the step in that direction, and led M. E. Schwartz to observe that the carbonaceous mass of Robiquet, if carefully washed and neutralized, could be used as a dye-stuff. MM. Lagier and Thomas improved upon this, and introduced, in 1839, an article which is now extensively used by calico printers and named garancine, and now is prepared as follows:—Madder, either unwashed, or, better still, washed with cold water, is mixed with one-third of its weight of sulphuric acid, which has been previously diluted with water till it marks 10° Twaddle; it is then boiled for four or five hours, and the mixture run on to woollen filters and washed till only a mere trace of acid remains. It is then either removed or washed once with a very weak solution of carbonate of soda, submitted to hydraulic pressure and then introduced into drying stoves. One hundred parts of madder yield from thirty-four to thirty-seven of garancine. Garancine is a fine powder of a light brown colour, and has a dyeing power four times as great as the original madder. It does not give as good blacks as madder, nor are its purple, red and pink so fast, but its purple is brighter, and the whites are obtained pure without soaping, it being only necessary to substitute a slight clearing liquor, composed of an alkaline, hypochlorite of soda, to which is added a small portion of sulphate of zinc.

In 1852, Messrs. Pinckoff and Schunck effected an improvement in the manufacture of garancine, their product being known in England under the name of commercial alizarine; but on the Continent it is better known as *Pincoffine*. Their process consists in submitting ordinary garancine to the action of high pressure steam of a temperature of 300° F., which, whilst it does not act on the alizarine contained in the garancine, destroys two other colouring matters which are present. These Dr. Schunck has isolated and examined, and named *Rubertine* and *Rerantine*. They are of a peculiar resinous nature, and spoil both the whites and the purples, which are fixed along with alizarine in the dyeing process. The employment of commercial alizarine is especially advantageous in the production of purples, which are faster and more brilliant than those produced by ordinary garancine. The cloth also does not require either soaping or cleansing.

M. Pernod has, within the last two or three years, introduced a madder extract, which is at the present time extensively used in Lancashire as a topical colour. This term is applied to a colour which is printed on a fabric, and afterwards fixed by steaming. By this method bright and fast colours are introduced in printed goods, producing much more effective designs than could be effected if the goods had to pass through a dye-beck and afterwards be washed with large quantities of water. Some splendid specimens of this class of printing were to be seen at the last Universal Exhibition, 1867.

To prepare the extract, garancine is lixiviated till completely exhausted, with a nearly boiling solution of sulphuric acid, containing five parts of acid to a thousand of water. On cooling, an orange-red precipitate falls to the bottom of the vessel, which, when collected and thoroughly washed, constitutes an extract ready for use. The products of M. Leitenberger and Messrs. Schaaffer and Lauth may be substituted for this extract.

As the employment of these extracts is the most important improvement recently introduced into calico-printing, I will give the three following recipes for their application:—To produce dark red, take 8 lb. of extract of madder, 4 lb. acetic acid and $1\frac{1}{4}$ lb. starch. Boil these in an earthenware vessel, and, when cold, add to six measures of the above one of acetate of alumina and a very small quantity of Gallipoli oil, say 1 per cent. For a pale red, take 4 lb. of extract of madder, 2 lb. of acetic acid, 10 quarts of gum Senegal water, and 1 pint of acetate of alumina. To obtain a purple, take 1 pint of extract of madder, half pint of acetic acid, half pint of water, and 3 oz. starch; boil, and when the mixture is cool, 5 oz. measure of acetate of iron of 24° Twaddle and 5 oz. of water. To produce a chocolate, proceed as in the last recipe, substituting acetate of chromium for the acetate of iron.

The above mixtures are printed on cloth by means of engraved copper rollers, and are then dried and submitted to dry high-pressure steam for one or two hours, when the colours have become fixed on the fabric. After being slightly soaped, to remove all excess of colour, the prints are stiffened and ready for the market.

Although I have now concluded my lecture on madder as a dye-stuff, and have already exceeded the time allotted to me, I hope you will allow me a few minutes more, to enable me to give an outline of the processes by which madder styles are produced, the more so as there may be some persons present who are not aware how madder and garancine prints, now manufactured in such enormous quantities and in such general use, are produced.

To effect this, the ordinary white calico, as sold in shops, is not sufficiently deprived of its impurities to be employed in madder or garancine styles; it has, therefore, to undergo further bleaching operations. The calico, so extra bleached, is then printed by means of copper rollers, on which the pattern to be produced is engraved. This roller leaves on the calico a red, purple or chocolate mordant; that is, for red, a sulpho-acetate of alumina, or red mordant; for purples, violets and blacks, an impure acetate of protoxide of iron, known in the trade as pyrolignite of iron or black liquor; and for chocolates a mixture of these two mordants.

After this operation the pieces undergo a process technically termed ageing. This was formerly effected by spreading out the pieces and hanging them in a room for three or four days, so that the acetate of alumina might lose part of its acetic acid, and the iron mordant nearly the whole of it, thus liberating the oxide of iron and enabling it to undergo partial oxidation.

Some few years ago, Mr. David Thom introduced a process by which this is effected in twenty minutes; it consists in passing the printed mordanted cloth over rollers fixed in a machine placed in a chamber about twenty feet long, in which a current of air and steam is thrown. The temperature of this chamber must not be below 100° nor above 108°, and the quantity of steam present must be such that fifty yards of calico will take up one ounce of moisture during the twenty minutes it is passing through the chamber. The printer is able to test the state of the chamber by means of wet and dry bulb thermometers. The next operation to which the cloth is submitted is dunging. The process received this name because formerly the calico was passed through a mixture of cow-dung with water. Now, however, silicates or arseniates of soda, mixed with a little chlorate of potash, are substituted. After passing through either of these solutions they are washed and ready to be passed through the dye-beck. This beck contains water, and from five to seven pounds of madder, or one to two and a half pounds of garancine, or commercial alizarine, for each piece of calico to be dyed. The heat of the bath is then gradually raised, by means of a jet of steam, to 180° for garancines or 212° for madders. This operation takes from one and a half to two hours, according to class of goods, style, etc. The fabrics are then washed and passed through a cleansing liquor for garancine or commercial alizarine styles, or soaped twice at 180° when they are dyed with madder.

The most permanent and brilliant colour produced from the rubia plant on cotton fabrics is Turkey red. The details so essential to success in dyeing this colour are kept by each dyer a secret, but I will attempt, as briefly as possible, to give the main features of the process. After the bleaching of the fabric is completed, they are passed through Gallipoli oil, and then exposed to the atmosphere in heated chambers. This operation is repeated several times. The next one consists in passing the cloth through a weak alkaline solution. After this, they go through a solution of acetate of alumina, and then through a bath of a tannin substance. By these processes, no doubt, the fatty acids of the oil combine with the alumina, as does the tannic acid of the tannin matter, helping to fix the mordant in the fibre of the fabric. On being dyed, the goods assume a rich dark red tone, to which brilliancy is imparted by passing the dye fabric through heated soap solutions.

I should occupy too much of your time were I to attempt to enter into the details of the methods by which chemists determine the relative tinctorial powers of roots, madders and garancines, but I may give you a very simple method of detecting ordinary adulterations of garancine by dye woods and tannin matters. Pieces of blotting-paper are dipped into a weak solution of chloride of tin and sulphate of protoxide of iron, and on each of these sheets is sprinkled a little of the suspected garancine. If a dye-wood be present, the chloride of tin-paper will assume a red colour, and, if tannin matter be present, the iron-paper will be blackened.

Parliamentary and Law Proceedings.

Infringement of the Pharmacy Act.

The following report of a case which came before the magistrates at the Croydon Police Court, on Saturday last, is taken from the *Croydon Times* of that date:—

Alfred Harrington, chemist, of Queen's Road, Croydon, was summoned on the information of George Hayward, chemist, of Windmill Road, Croydon, for selling on the 7th of November, to a man named Stent, certain poison, to wit, oxalic acid, in a wrapper or a cover which was not distinctly labelled with the name of the article sold, and the name and address of the seller of the said poison.

George Hayward, chemist and druggist, of Windmill Road, deposed that on the 7th of November he sent a person named Stent to the defendant. He brought him back a packet, on the wrapper of which only the word "poison" appeared. The contents of the packet were oxalic acid.

Defendant admitted that the packet contained the acid referred to.

Complainant, in answer to the Bench, said it was not a transaction between traders, but was a *bonâ fide* one of a customer.

The defendant was not a registered druggist or a member of the Pharmaceutical Society.

Stent, who is a bricklayer, said that he received certain directions from Mr. Hayward, and went to Mr. Harrington and asked him for one pennyworth of the same stuff as was on the paper, which had written upon it oxalic acid. Defendant wished to know what he was going to use it for, and witness told him to clean brass with. No name was mentioned whom it was for. He gave it to witness, who paid him one penny. Witness then took it to Mr. Hayward.

By defendant—Defendant did not say the writing was Mr. Hayward's. He said nothing about Mr. Hayward.

Defendant denied trading with Hayward, and said it was only an accommodation of one from the other. He accused the complainant of having a feeling against him for some unknown purpose.

The Chairman told the defendant that there was not the least doubt as to his being guilty of what he was charged with, and the Bench had no alternative but to impose a penalty. The punishment the Bench intended to inflict upon him was that he should pay a penalty of 6*d*.

The complainant was ordered to pay the costs.

Reviews.

Storia della Farmacia e dei Farmacisti, appò in Principali Popoli del Mondo. Per Federigo Kernot. Naples. 1871.

Second Notice.

The first part of this interesting book gave a general outline of ancient history, and we come now to the second part, which the author opens with a chapter on the often-ventilated question of the proper position of the pharmacist; the writer assigns him a high position among scientific men, and he deeply deplores the manner of bringing out numberless specifics and patent medicines as one of the causes which degrade the pharmacist to a trader and shopkeeper, and which profane the sanctuary of the science.

Passing on to the state of pharmacy in different countries, the author begins with England, and his description of our institutions, if not correct, is highly amusing; after having enjoyed more than once in a hearty laugh, we could not but regret, and we must strongly express it, that a work written and compiled with so much care and diligence, should be disfigured by such ridiculous nonsense as many of the statements are. Mr. Kernot speaks of what he saw and learnt amongst us, but we wonder who his guide and interpreter was, because we have learnt a great many things from his book, which we never saw or heard of before. There is a strange confusion of the names of pharmacists, of apothecaries and surgeons, of druggists and chemists and of "*herborists*," which we may well excuse in a foreigner; the apothecary and surgeon holds a position, which, according to the author, forms such a scandalous and odd combination, that it lends a queer and comical side to English life. How busy these gentlemen are; how they run past the shop of the legitimate pharmacist to pay their visits at 5*s.* apiece; how they rush back to their business to compound the medicines for their patients; and how they offend the well-known feeling of English delicacy and prudery. In the windows of some of those gentlemen the author found the inscription, "*delivery room*" (sala disgravi), and to make any mistake impossible, he dilates on the gross impropriety of this institution. We can only surmise that Mr. Kernot saw this inscription at some wholesale house for the delivery of goods, and that a reference to his dictionary suggested a different tale, at which he justly grew very indignant.

The chapter on Spain gives all the laws, but it does not contain anything new to our readers, especially after the recent account of Dr. Ullersberger's history of Spain.

Germany, next in order, is fairly and fully treated, great justice is done to the careful training and instruction of those who devote themselves to the study and practice of pharmacy, which, almost as a matter of course, must secure the high social position the German pharmacist undoubtedly holds. The sometimes very complicated relation of the State and the pharmacist, the examinations and other internal arrangements are so carefully given, that altogether this chapter is one of the best parts of the book; the author is here well at home, and it is the more surprising that he finishes off with a story as contrary to facts and as unlikely as that of the general practitioner and his delivery-room. Who ever saw, at Berlin, an *ehrlicher Apotheker* "go to a patient with a porcelain basin, a towel, a jug of hot water and a supply of leeches"? Well may the author say that the whole appearance of this grave German in black, with white cravat and white gloves, who thus marches out to earn his thaler, is so amusing that an Italian traveller can scarcely help laughing right out.

Leaving the civilized world, the author takes his reader to the barbarians, amongst whom the Chinese stand foremost; with them medicine is quite in its infancy, and savours much of quackery. Itinerant quacks supply the mass of the people with any medicine they require in the most comfortable manner; the quack has his remedies in a box divided into as many compartments as the diseases he cures; the patient merely states his complaint, and without further inquiry the proper medicine is handed over. John Harrow, in his 'Travels through China,' relates how one of these quacks, in Canton, sold a powder as an antidote for snake-bites, the efficacy of which was demonstrated on the spot; the charlatan carried a poisonous snake with him and held it to his tongue, which in a few minutes swelled up to such an extent that the mouth became almost too small to hold it; to excite the compassion of his customers he seemed to suffer most horribly, but at last he put a little of the powder on his tongue, which instantly resumed its natural size, and of course the powder sold wonderfully.

If the poor Chinese are so easily taken in, the higher classes, the mandarins and rich merchants, are much wiser. They make it the physician's interest to cure them as speedily as possible; the physician is paid by the year, but every time his advice is required a deduction is made, and if unfortunately the patient dies, the doctor has to submit to a further reduction of his honorarium corresponding to the duration of the illness.

Various plasters are held in high estimation; some of these act locally, others are preventive of all kinds of diseases, while others again are applied in venereal diseases.

The Chinese pharmacist is looked upon as one of the *savants* of the town; his shop is kept in first-rate order, the medicines are prepared with the greatest care, and his drugs and herbs are of the best quality. The shops are similar to ours, with numbers of drawers and bottles, but extremely plain and simple.

Camphor, rhubarb and liquorice are frequently used, but purgative salts, calomel and all tinctures are unknown. Strange to say, opium, so much indulged in by the Chinese, has no place in their materia medica.

On the other hand, China seems to be the very land for the patent medicine vendor. On the pharmacist's counter we find large boxes, with preparations which instantly cure cholera or confer strength, or impart courage or excite love, so that almost every taste or desire may be gratified.

The doctor is very slow in writing down his prescription, which fills a large sheet of paper, the lines being written alternatively in red and black characters, an occupation lasting from one to two hours. The pharmacist, on receiving the prescription, places it on his counter, and carefully studies it, after which he commences to make it up *lege artis.* Every preparation is wrapped up in white or red paper, the first enclosing the more common articles, whereas the last is only used for expensive substances, as, for instance, the "ginseng." This is the supreme remedy for securing health, prolonging life, and regenerating the whole body. Of course only very rich people can indulge in this luxury, which is so costly that an ounce costs about £5.

The practice of pharmacy is not limited by any legal formality. Every one has the right to open a shop without previous special knowledge; but practically the business is confined to certain families, in which it passes for generations from father to son.

Generally speaking, we may say that the Chinese have no idea of applied natural philosophy or chemistry, but follow their business mechanically and empirically. Here, as in everything else, seclusion from the rest of the world results in perfect stagnation.

Leaping from China to Turkey, we learn that chemistry in Turkish is termed "elsié," whence "elisire," "elixir," a chemical beverage. The Turks also have their favourite compounds, the most noble of which is the "maggium," a mixture of opium, cinnamon, aloes, saffron, cloves, and other spices, which, in the form of pills, is sold in enormous quantities under the name of "habb." The "maggium" or "magic" compound of the upper classes is composed of ambergris, powdered pearls, rubies, emeralds, corals and cochineal. The price of a small bottle is 400 silver piastres, or more than £6 sterling, but this costly mixture is only used by the Sultan and the highest of the realm.

"Tenasne" is an odorous paste, consisting of musk, aloes, ambergris, powdered pearls and attar of roses. Small quantities are taken in coffee, or it is formed into pastilles, and sold under the name of "masch'alla."

Once a year the "escimbaseé," or first physician, and the "gerrabaseé," the principal surgeon to the Sultan, must offer some "maggium" and some "tenasne" to their master, for which they are entitled to a rich present in return.

The final chapter is devoted to Italy, at last united, with Rome for her capital. After a glance at the ordinances under former separate governments, we find extracts from more recent laws, which certainly lead us to assume that the pharmacist's position there is more honourable and more respected than in many other countries. In a few concluding words, the author of this interesting, and in many parts instructive work, winds up with an ardent desire for a European Pharmaceutical Association, which more than any other brotherhood would advance the grand objects of humanity.

A Manual of Therapeutics, considered chiefly with reference to articles of the Materia Medica. By Edward John Waring, M.D., F.L.S. Third edition. London: J. and A. Churchill. 1871.

Dr. Waring's book maintains its character as a useful compilation. In this edition he has introduced the results of a diligent perusal of the medical publications since the appearance of the last. Of the British and American periodicals he seems to have kept well abreast; of the French not so well; and of the most important of all—the German—hardly at all. If he does refer to the therapeutics adopted in the *Klinik* of Vienna or Berlin, it is nearly always at second-hand, as the information has come filtered to him, not invariably in its original purity, through one or other of the home journals. This is a serious defect, vitiating his book as a reflex of contemporary practice hardly less seriously than a like omission would vitiate an English work on chemistry or physiology. Another cause of lessened confidence in his prescriptions is his want of discrimination between the authorities he cites: a general practitioner, for example, being quoted as of equal weight with a first-class hospital physician; or the results (possibly exceptional) of one or two administrations of a drug being advanced as warranting its use in cases only superficially similar. What, for example, can be less satisfactory than the treatment he prescribes for epilepsy,—a malady which appears in the Index as susceptible of about sixty remedies, several of which he notes as preferable by an asterisk, while the mass of them are recommended on the authority of third-rate, or even fourth-rate practitioners! Compilations are useful in proportion to the judgment and skill of the compiler; and though Dr. Waring, especially from his experience in the tropics, is by no means wanting in those requisites, he takes too much at second-hand (and even that on trust) to become the guide of any but the more general of practitioners, or the less particular of medical officers.

BOOKS RECEIVED.

The Liverpool Medical and Surgical Reports. Edited by P. M. Braidwood, M.D., and Reginald Harrison, F.R.C.S. London: J. and A. Churchill. Liverpool: A. Holden. October, 1871.

Symptoms and Treatment of Malignant Diarrhœa; better known by the name of Asiatic Cholera. By William Marsden, M.D. Fourth Edition. London: Wyman and Son. 1871.

Inorganic Chemistry. By the late George Wilson, M.D., F.R.S.E. Revised and enlarged by H. G. Madan, M.A. London and Edinburgh: W. and R. Chambers. 1871. From the publishers.

Smoking; when Injurious, when Innocuous, when Beneficial. By John C. Murray, M.D., F.A.I. London Simpkin, Marshall and Co. 1871.

MEETINGS FOR THE ENSUING WEEK.

Monday Nov. 20.	*Medical Society*, at 9 p.m. *London Institution*, at 4 p.m.—"Bodily Motion and Consciousness." By Professor Huxley. (Educational Course.)
Wednesday Nov. 22.	*Society of Arts*, at 8 p.m.—"On the Present State of the Through Railway Communication to India." By Mr. Hyde Clarke.
Thursday Nov. 23.	*Royal Society*, at 4 p.m.—Annual Meeting. *London Institution*, at 7.30 p.m.—"Science and Commerce, illustrated by the Raw Materials of our Manufactures." By Mr. P. L. Simmonds.

The following journals have been received:—The 'British Medical Journal,' Nov. 11; the 'Medical Times and Gazette,' Nov. 11; the 'Lancet,' Nov. 11; the 'Medical Press and Circular,' Nov. 15; 'Nature,' Nov. 11; the 'Chemical News,' Nov. 11; 'English Mechanic,' Nov. 10; 'Gardeners' Chronicle,' Nov. 11; the 'Grocer,' Nov. 11; the 'Journal of the Society of Arts,' Nov. 11; the 'Chemist and Druggist' for November; 'Food Journal' for November; 'New York Druggists' Circular' for November; the 'Croydon Times,' Nov. 11; 'Dublin Quarterly Journal of Medical Science,' November.

The Preliminary Examination.

Sir,—The general impression is, that the standard of the Preliminary Examination is too high; and, certainly, from the number that failed at the recent Examination, this opinion appears to be correct.

But ought not the standard to be high for such an elementary examination? For a youth cannot be said to have had a middle-class education who is incapable of answering twelve at least of the twenty questions set; and I should think that that proportion would pass him, inasmuch as the College of Preceptors give a special certificate for any subject on which a candidate has obtained three-fifths of the total number of marks assigned. Surely this examination cannot be made much easier. Compare it with like examinations; take, for instance, the Preliminary of the Royal College of Surgeons of England. In the former there are three compulsory subjects, and in the latter there are ten.

I do hope that in future the Preliminary Examinations of the Pharmaceutical Society will be more rigid, and embrace a greater number of subjects, and then none but the well-educated will become pharmacists.

November 13th, 1871. W. A. M.

Dear Sir,—The following appeared in a provincial paper, October 28th, 1871:—

"Pharmacy Act.—N— B—, now with Mr. J. M. W—, pharmaceutist, O—, presented himself for examination at S— on the 22nd instant, and, in accordance with the rules of the Pharmaceutical Society, was examined in the following subjects:—'Cæsar's Commentaries' (De Bello Gallico), English and Latin Grammars, Composition and Arithmetic; and, having passed with facility, was duly registered."

I presume this was inserted as a cheap way of advertising the establishment to which this learned gentleman belongs; at any rate, it seems to me to be making a little too much noise on passing such an examination as the Preliminary. The pages of the local print ought certainly to be regularly examined, as we may expect a grand report when this gentleman succeeds in his Minor.

W. H. J.

The Tincture Press.

Sir,—The vexed question as to the power capable of being exerted by a man of ordinary strength when turning the lever of a laboratory press can only be settled by experiment. The doing so is so simple a matter that I wonder one of the principal disputants has not ere now enlightened us on the point.

I have endeavoured to supply the omission—in this way. I fastened securely to a beam a four-inch iron pulley, and passed over it to one extremity of the horizontal press-lever a rope which was securely fastened there. The other end of the rope was attached to a board resting on the ground, and on this was piled the weight to be lifted. Mr. Umney will be surprised to learn that a man of average strength can thus raise upwards of 200 lbs. The weight actually raised, and that without extraordinary exertion, was 216 lb., which was effected by four male adults in succession. I have no doubt that 250 lb. would be nearer the limit, provided that the lever be in its best position for the exertion of one's strength, and the power be not diminished by the friction of the pulley, etc. I must explain that my press stands in a recess, and therefore it often happens that the lever does not come round to its best position at the right time. I think of substituting a wheel of the same radius, and thus shall overcome the objection.

Professor Rankine's figures must apply to the *average* amount of power exerted by a labourer during a day's work, and can have no possible reference to such a case as the momentary extreme effort one makes when working a press-handle.

It would obviously be impossible to exert such a force on the press of Mr. Staples' design. In the first place, the press must be securely fixed; secondly, the threads of the screw must be stout enough to withstand the pressure; and lastly, the rod bearing the screw must be stiff enough to resist torsion. I grant that, by applying the power to the nut and not to the screw-head, the tendency to twist is greatly diminished; nevertheless, the friction of the metal surfaces (without which the screw would be useless, as it would run back directly the hands were removed from the handle) must produce a considerable strain of that kind. Mr. Staples would, I think, be disillusionized as to the power of his press, were he to test the endurance of his wooden cross-beam E. It obviously is unable to bear anything like the pressure credited to it. Mr. S. has satisfactorily cleared up the doubt some appear to have entertained as to the superior efficacy of two screws over one.

The idea of interposing a spring between the screw and the marc to be pressed, is, I think, a good one. A metal spring, however, could not be obtained of sufficient strength without incurring great expense. I propose trying the following:—A cylindrical box of iron, about 4 inches deep, and of a diameter equal to the press-body, will contain an india-rubber bag that exactly fits it; on this will be placed a strong cover, thick enough to stand the force of the screw, and having guides on its side to prevent it tilting. It will have to be turned in a lathe so as to exactly fit the cylinder and offer no crevice for the india-rubber to be forced into when under pressure. The air contained in the bag will, of course, be the spring, and being permanently elastic, be capable of sustaining any amount of force one can put upon it. Practical difficulties will, I suppose, crop up. I look forward with apprehension to the bursting of the cylinder, leakiness of the bag, etc. However, should I try it, I will candidly report results.

There can be no doubt of the advantage that would be gained by giving to the pressure a degree of permanence, and to attain it is worthy of an effort.

I have a press constructed like a cheese-press, except that its lever is compound. The nominal pressure exerted by it is 5 tons. As the weights descend they are raised again by a screw and lever. In some respects it is useful, but I found that its power was far inferior to that of my large press with lever of 14-inch radius and screw-threads half an inch apart. The iron cross head or nut of this press I may mention is 3 inches deep in the centre, and is the third that has been fitted to it; the previous ones having been unequal to the occasion. This perhaps is accounted for by its having sometimes to submit to the united forces of two strong men, who would together exert a force of at least 350 pounds.

The compound hydraulic press of Desgoffe, a very useful and ingenious machine, is, I fear, too expensive for the ordinary retail druggist. I have often had it in my mind to adapt to the ordinary press some means for giving the marc a final pinch at the end of the operation. Hunter's differential screw, worked by means of a powerful lever and advancing one-sixteenth of an inch each revolution, would give a very powerful pressure, and would, doubtless, be cheaper to construct originally and less liable to get out of order than a hydraulic arrangement.

The fact, often lost sight of, that the intensity of the pressure exerted is proportional to the area over which it is spread,—so that, other things being equal, the intensity is doubled by the area being reduced to one-half, and *vice versâ*,—enables one to achieve, when desired, a more complete exhaustion of the marc, and tends to equalize the power of large and small presses.

THOMAS B. GROVES.

THE CHLORAL CONTROVERSY.

Sir,—Your remarks on chloral are interesting: the quantity given (half a ton) would not amount to more than about half an ounce to each of the 20,000 practitioners in Great Britain and Ireland; this the *Echo* refused to state. I find this paragraph as to a Lunatic Asylum in one of the journals, "The amount used is ninety pounds in 370 cases! In one case 20-grain doses were given for 257 consecutive nights, with the happy result of securing refreshing sleep; the patient recovered." We need scarcely require then the extraordinary conjecture of the *Echo*, that as chloral is cheaper than cocculus indicus, the chemists and brewers are in league to supply it in tons to our beer and ale shops!

CHARLES KIDD, M.D.

Sir,—Although much has been said respecting this remarkable substance, doctors seem as little likely to agree respecting its properties as ever.

A case in point may serve as a comment upon its alleged cumulative power. A gentleman, for whom I recently dispensed, took nightly at 9 P.M. 35 grains, and at 3 A.M. 45 grains of the crystalline salt during the space of nearly three months.

If the opinion held by some authorities be correct, the man ought to have died long since; instead of which, his medical attendants report that the case is progressing favourably.

Some misconception seems to exist as to the quantity of chloral hydrate actually made; but the consumption must, of necessity, be very large if the above-cited case is to be taken as an average.

Australia alone consumes a large proportion of what is exported from this country.

R. GOODWIN MUMBRAY.

Richmond, S.W., Nov. 15th, 1871.

SPURIOUS SPECIMEN OF HEMLOCK FRUIT.

Sir,—While preparing for the Minor examination, a short time ago, I had occasion to make use of a collection of Materia Medica specimens, which had been supplied by a first-class wholesale house.

In going over the various specimens it contained, I came upon a parcel labelled "Conii Fructus," which, on examination, proved to be spurious, as it consisted almost entirely of other umbelliferous fruits, there being only a very few hemlock fruits intermixed. I have the parcel still in my possession. The greater portion appears to be the fruit of a species of *Caucalis* (*Torilis*), as it has a decided parsley taste, and is remarkably bristly, some of the bristles being hooked.

I enclose a specimen for recognition.

Such an occurrence ought to enforce on all engaged in the business the value of an intimate acquaintance with the several articles of the Materia Medica; and should also suggest the necessity of carefully examining all purchases of drugs, etc., no matter from what source they may be procured.

Belfast, November 13th, 1871. THOMAS GREEN.

[*** The parcel of umbelliferous fruits sent by our correspondent contains a mixture of three different genera at least. The proportion of *Conium* fruits is very low, the bulk being composed of the spiny fruits of a species of *Caucalis*, near *C. macrocarpa*.—ED. PHARM. JOURN.]

DIFFICULTIES IN DISPENSING.

Sir,—In Mr. Wilkinson's paper, published in last week's Journal, I find the recommendation of a most objectionable practice unchallenged by the meeting before which it was given.

The practice is that of making material alteration in a prescription without the sanction or the knowledge of the physician; such as omitting a portion of an active ingredient altogether, or substituting for it another of different power.

I am more especially led to draw your attention to the matter, as in each of the cases given no such difficulty exists as to render the change necessary.

Stockton, November 14th, 1871. T. B.

Erratum.—We are requested by the Hon. Secretary of the Leeds Chemists' Association to make the following corrections:—In the report of the annual meting of that Society, *ante*, p. 347, col. 1, l. 36, for "party influence" read "parliamentary influence."

C. Gerring.—Rub the turpentine with the yolk of egg in a mortar, add rose water as required, transfer to a bottle and shake with the acetic acid, then gradually add the remainder of the rose water.

W. Owen.—Rub the acetate of morphia with the glycerine, and add to the oil and chloroform previously mixed.

"*Juniperus Sabina.*"—The specimens forwarded are all from *Juniperus Sabina.*

COMMUNICATIONS, LETTERS, etc., have been received from Mr. J. R. Jackson, Dr. De Vrij, Mr. M. C. Cooke, Mr. F. Wheeler, Mr. David, Mr. W. Bates, Mr. W. S. Brown, Mr. S. Payne, H. E. R., T. B.

NITRITE OF AMYL.*

BY ALFRED B. TANNER.

Nitrite of amyl is a comparatively recent addition to our materia medica; so far as I can discover no notice of its employment therapeutically in this country occurs previously to September, last year (1870), when Dr. Richardson—in an editorial paper in the *Medical Times and Gazette*, and which was subsequently copied into the other Journals, the Pharmaceutical included—gave some very interesting results of his experiments with nitrite of amyl, and quoted several cases of its successful employment in a very distressing disease, called angina pectoris. It, however, appears to have had a very limited use in medicine until quite recently, when Dr. Talfourd Jones published a paper in the *Practitioner*, and also one in the *British Medical Journal*, describing the very great success he had met with in the employment of it in certain spasmodic diseases, besides the one previously mentioned, and in asthma and complaints of an allied character. It is not my intention to enter fully into the therapeutical portion of the subject, as I think this scarcely our province; my intention more particularly is to describe its physical properties, together with the method and difficulties of its preparation in a pure state and fit for medicinal use; still I think it desirable that we should know somewhat of its action and effects on the system also.

The earliest observed action on the system of this remarkable substance is due to F. Guthrie, in 1858, who specially observed that on inhaling its vapour, it caused flushing of the face and strong pulsation of the carotid arteries, with a much increased action of the heart; these effects led him to the supposition that it would be a valuable restorative in cases of drowning, suffocation and suspended animation generally. Dr. Richardson also showed that the inhalation of its vapour was followed by an increase of the heart-action to a much greater extent than could be produced by any other known agent, also that the face and surface generally became deeply flushed; when the inhalation had been carried to a considerable extent, the breathing became excited and breathlessness was produced, like that caused by violent exertion as running, rowing, etc. In no case was anæsthesia produced by it. Its use in angina pectoris was first advocated by Dr. Lauder Brunton. The latest investigations into its use in disease are those before referred to by Dr. Talfourd Jones, who seems to have used it extensively; he states that it may be administered by the mouth, by inhalation or by subcutaneous injection, but that the safest method is inhalation; he used five drops on a piece of lint and held close to the nostrils for ten or twenty seconds, or until acceleration of the pulse and flushing of the face commences. His paper is a most interesting one, and may be found in the *Practitioner* for October this year; in the same paper, also, occur some suggestions for its employment as an antidote to counteract the effects of an overdose of such medicines as chloral, ergot, etc. But by far the most important suggestion for its employment, is that by the same author, given in the *British Medical Journal* for September 30, 1871, and which, if realized, will go far to make it one of the most remarkable and beneficial medical discoveries ever made,—it is its employment as a remedy for the collapse and cramps of cholera. No experiments in this direction appear yet to have been made, but from the very able and lucid arguments brought forward in his paper, there appear every probability of its being the true remedy for this dreadful disease. It is, undoubtedly, a remedy of great power, and will, doubtless, come into pretty extensive use. Having given this slight sketch of its therapeutical employment, I will now proceed to a description of its physical qualities and method of its preparation.

Nitrite of amyl, like most other substances of its class, was known to the chemist long before it was made use of in medicine; to M. Balard, in 1844, is due the discovery of this substance.

It is an amber-coloured liquid, with a taste and smell reminding one something of ripe pears; but it is remarkable that nearly all the compounds of the amyl group possess something of this peculiar odour. Its formula is $C_5 H_{11} N O_2$, and it is a corresponding compound to nitrite of ethyl, $C_2 H_5, N O_2$, which is contained in the spirit of nitrous ether of the Pharmacopœia. When pure and perfectly dry, nitrite of amyl has a boiling-point of 99° C.; when containing moisture, as it usually does, the boiling-point will be some few degrees lower, say about 96°, and this is the figure given by Balard. Another authority (Rieckher) states its boiling-point to be 91° C., and these discrepancies are, doubtless, owing to the fact before mentioned, viz. the presence of moisture; this being supposed to diminish the cohesion between the liquid and the glass, and so cause the ebullition to take place at a lower temperature, which is the case with almost all liquids,—their boiling-points being higher when boiled in glass vessels than when boiled in metallic ones, on account of the increased cohesion, owing to the extremely smooth surface which glass vessels present in comparison with metallic ones. The sp. gr. of pure nitrite of amyl is ·877; it is almost insoluble in water, but freely so in ordinary alcohol, ether, chloroform, benzole, etc.; it is itself a solvent of fats, oils and fatty acids; sulphur and phosphorus are but sparingly dissolved by it. Unlike the nitrite of ethyl, it does not appear to be decomposed or suffer any change by keeping; I have some which I prepared some twelve months since, and which appears as unchanged as when it was prepared, and is neutral to test-paper. Nitrite of amyl is usually prepared by passing nitrous gas into purified amylic alcohol, at a temperature of 132° C., the boiling-point of the amylic alcohol. This process is a very tedious and unsatisfactory one, as was pointed out in a recent number of the PHARMACEUTICAL JOURNAL, by Mr. J. M. Maisch. Five ounces and a half of purified amylic alcohol require from eight to nine hours before becoming completely saturated with the gas; in addition to which, the product is very impure and small in quantity; fractional distillation being necessary to get anything like a pure product. The impurities are for the most part ethyl-amylic ether, amylic aldehyd and very considerable quantities of hydrocyanic acid, all formed during the decomposition of the amyl alcohol by the nitrous gas. The nitrous gas is produced by reducing $H N O_3$ by means of starch in a glass-flask and conveying the vapours into the amylic alcohol heated to 132° C. The process first suggested for its formation by Balard, in 1844, consists in introducing into a capacious glass-retort, capable of holding at least four

* Read at a meeting of the Liverpool Chemists' Association, November 9th, 1871.

times the quantity, a mixture of equal volumes of amylic alcohol and HNO_3, the retort being connected with an efficient condenser, a gentle and very gradually increasing heat is applied; after rising to a certain temperature the source of heat is withdrawn and the reaction allowed to go on by itself. Considerable frothing and violent action take place if the heat has been too long applied; the thermometer inserted in the tubulus of the retort rapidly rises, and the product produced is collected until the temperature rises to 100° C., after which the receiver is changed, as the product then becomes too impure to be of any use, containing as it does nitrate of amyl and ethyl-amylic ether; this may be readily distinguished by the change there is in the odour of the distillate. The product which was collected before the temperature reached 100° C., is now treated with a solution of $NaHO$, which removes and fixes both the free HNO_3 with which it is sure to be contaminated, and also the HCN, formed during the decomposition of the amylic alcohol by the nitrous gas; in this reaction, omitting secondary decompositions, the HNO_3 is reduced to HNO_2, which attacks the amylic alcohol forming nitrite of amyl. Of course this reaction is nothing like perfect, or we should have the pure nitrite without further trouble; part of the nitric acid escapes decomposition entirely, hence the presence of nitrate in it. HCN, also, is formed, and may be detected in the alkaline solution used for washing the impure product, in the form of KCN or $NaCN$, as the case may be; it may also be detected in the product itself, by means of a drop of $AgNO_3$ placed in the centre of a watch-glass and inverted over another glass containg a small quantity of the impure nitrite; $AgCN$ is produced in the form of a white film on the surface of the drop. The washed product is separated by decantation or by means of a pipette and introduced into a clean retort and again slowly distilled. That portion which comes over before the temperature reaches 96° C., contains the amylic aldehyd; this is set aside and a fresh receiver placed. That collected between 96° and 100° C., consists for the most part of nitrite of amyl. After the temperature has risen to 100° C. the distillation is stopped; the retort will contain the ethyl-amylic ether, whose boiling-point is above 100° C. The yield by this process is very small, and it is in many respects inconvenient. Another process for preparing this substance is given by Nalder, which he says readily yields the pure nitrite, but the merits of which I am unable to state, having never had experience with it; it consist in distilling amylo-sulphate of potash with nitrate of potash. Judging from analogy, if this process yields pure nitrite of amyl, it ought to be a very efficient one for the preparation of nitrite of ethyl, and, consequently, for spirit of nitre, a good process for which is still a desideratum; of course, in the latter, it would be necessary to use ethyl-sulphate of potash instead of the amyl compound. I am not prepared at present to state what difficulties there may be in the way of preparing the amyl-sulphate of potash; the ethyl compound is not difficult to prepare, and a process for it may be found in most text-books on chemistry.

The process by which I have been in the habit of preparing nitrite of amyl, and of which I now intend giving you a description, is one which I think will be found convenient for its preparation on a small scale, and of sufficient purity for medicinal use. I do not claim any originality for it, as it is probable that many may have thought of it although not put it into practice. So long ago as July last year, while making spirit of nitrous ether by the Pharmacopœia process, the idea occurred to me that, with some modification, this might be made a convenient one for the preparation of nitrite of amyl. A demand for the latter arising just then, I put it into practice. In Mr. Maisch's paper in the April number of the Journal for this year, he states that the same idea occurred to him, but that he found it not to answer, and this I think may be easily accounted for. The process for spirit of nitrous ether, as you are all aware, consists in distilling, at a certain temperature, a mixture of rectified spirit, sulphuric and nitric acids in certain proportion, and copper wire; the distillate consists mainly of a mixture of nitrite of ethyl and ethylic alcohol. Now, by substituting amyl alcohol for the rectified spirit in this process, you get nitrite of amyl among other products; but Mr. Maisch appears to have overlooked one fact, viz. that rectified spirit contains 16 per cent. of water, and that the amylic alcohol he used was nearly anhydrous. He states that the amylic alcohol, *i. e.* the purified substance, was mixed with sulphuric acid, the mixture introduced into a retort, together with some copper wire, and, after cooling, HNO_3 was added. In a very few moments the evolution of gas was observed, the liquid became hot without the external application of heat; and the reaction very rapidly increased to such a violence that the entire charge was lost, it being impossible to condense any of the vapours in a Liebig's condenser, or to retain much of the liquid forced over into the receiver. I may add, that I have repeated this experiment with exactly the same results; nearly the whole charge was forced over into the receiver, and, while there, the action again commenced, and increased to such violence that I have no doubt it would have forced itself back into the retort again if their mutual positions had been favourable. As it was, I was obliged to introduce it to the open air, for the whole house became filled with the vapour, and every one who respired it became suddenly red in the face. Upon one of my assistants it had a very remarkable effect; it seemed to affect the muscles at the back part of the neck, and drew the head backwards, but this soon passed off. I should quite expect that the reaction would be just as violent in making spirit of nitrous ether, if we used anhydrous alcohol instead of 84 per cent. as ordered. In preparing the nitrite of amyl by the process I employ, it is of the utmost importance that the amylic alcohol be as pure as possible. Amylic alcohol, as you all know, is formed during the fermentation of potatoes, rye, barley and the marc of grapes; and when these are distilled it communicates a very pungent, and to many repulsive, odour and taste to the spirits. It is considerably less volatile than either ordinary alcohol or water, having a boiling-point, when pure, of 132° C.; in consequence of this property, it accumulates in the last portions of the liquids that are distilled. Its name is derived from *amylum*, starch,—this being the most abundant constituent of potatoes. Liebig states that amylic alcohol is formed principally in the fermentation of alkaline or neutral liquids, and its production in the potato mash may be prevented in great measure by adding crude tartar to the fermenting liquid. Its formation never occurs in acidulous fermenting liquors which contain tartaric, racemic, or citric acids. The addition of hops to the liquid has a similar effect in checking the development of amylic alcohol, or fusel oil, as it is generally termed. It is, when pure, a colourless limpid liquid, of a penetrating and disagreeable odour, exciting headache and coughing when its vapour is inhaled. It is sparingly soluble in water, though it mixes in all proportions with alcohol, ether and essential oils. It is not easily inflammable, but burns with difficulty, giving a bluish flame. Its specific gravity, when pure, is ·818, and boiling-point 132° C. Amyl alcohol is not acted upon by the atmosphere, except it be in a very thin layer, or under the influence of spongy platinum, when it is oxidized into valeric acid, $C_5H_{10}O_2$, which acid bears the same relation to amylic alcohol that acetic acid, $C_2H_4O_2$, does to ordinary alcohol. Fusel oil, as met with in commerce, is usually a clear yellowish liquid, with a peculiar penetrating odour, varying, of course, with the substance from which it has been produced. It has a specific gravity of from ·840 to ·850, and is largely contaminated with the lower alcohols of this series; so far as my experience goes, it is only about half pure amyl alcohol. As I have before stated, it is of the utmost importance, in the preparation of nitrite of amyl, that the amylic alcohol be as pure as possible, for it is much easier to purify this than to purify the nitrite produced from it in its impure state. For this purpose, the best process is first to agitate the fusel oil with about an equal bulk of a strong solution of chloride of sodium; this usually reduces its bulk about 16 or 20 per cent., and also considerably lowers the specific gravity. This washed product is separated and introduced into a retort furnished with a thermometer; that portion of the distillate which passes over before the temperature reaches 125° C. consists mainly of the lower alcohols of this series, and whose boiling-points are below that of amylic alcohol, for the boiling-point rises in proportion as the compound is richer in carbon. The distillate collected between 125° C. and 140° C. is collected apart, and redistilled until it has a boiling-point near 132° C.; this may then be considered pure enough for our purpose. This is then introduced into a glass retort containing some copper wire, and furnished with a safety tube, and one-tenth its bulk of H_2SO_4 added. The same quantity of HNO_3, diluted with an equal volume of water, is next put in, and a very gentle heat applied until the temperature reaches about 65° C., when the reaction will commence and proceed in a perfectly manageable manner, until a bulk about equal to double the quantity of HNO_3 added collects in the receiver, the temperature in the meantime rises to about 98° C. The reaction ceases very quickly, as in the case of spirit of nitrous ether. The temperature having fallen somewhat, another portion of HNO_3, equal in bulk to the first, is added, and this process of successive additions of the acid continued until nearly the whole of the amylic alcohol is exhausted, which may be known by the dense red fumes evolved from the retort. The distilled product exceeds in bulk the amylic alcohol used, and is the impure nitrite of amyl. This is washed with solution of $NaHO$ to remove the HCN and other free acids present, and rectified over fused K_2CO_3 to get rid of moisture. The portion which distils between 95° and 100° C. is collected as nitrite of amyl, sufficiently pure for medicinal use.

It has several times been stated that nitrite of amyl produces violent headache, and also coughing and irritation of the larynx; this, I think, must be due to its insufficient purification. The presence of HCN and undecomposed amylic alcohol would, I think, account for this; no such effect was produced on myself with the purified nitrite. Mr. Umney has shown, in an article in the PHARMACEUTICAL JOURNAL of November, 1870, that the samples then met with were very impure.

VESICATING INSECTS.

BY M. C. COOKE, M.A.

(*Continued from page* 384.)

ASSAM BLISTER FLY, *Lytta assamensis*, Water.; *Lytta tibialis*, Water.

Probably forms of the same species. *Cantharis assamensis*, and *C. tibialis*, C. Waterhouse in Trans. Ent. Soc. Lond. 1871, p. 407.

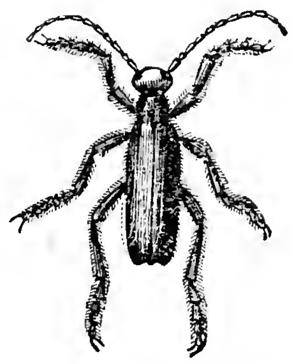

Fig. 8.—*Lytta assamensis.*

This species most nearly resembles *C. ruficeps* of Illiger, but is distinguished from it by the narrow margin of white pubescence to the elytra, and by the broad hairy anterior tibia in the male.

Male.—The head is reddish-yellow, and (with the exception of a smooth spot at the base of each antenna) somewhat thickly, and not very strongly punctured; the anterior margin of the clypeus is fuscous, as are the labrum and other parts of the mouth. The antennæ are filiform; the third to sixth joints each notched for the reception of the following joint; the third joint is about equal in length to the fourth and fifth joints together; the fourth, fifth, and sixth are rather short, nearly equal in length; the seventh to eleventh gradually increasing. The thorax is subquadrate (abruptly contracted in front), thickly, evenly, and distinctly, but not very strongly punctured; there is a slight impression on either side at the front, and a deep central fovea at the posterior margin. The elytra are scarcely broader at the apex than at the base, each rounded at the apex; the extreme margin and the suture fringed with white pubescence. The anterior tibiæ are broader towards the apex, thickly set with long black hair on the outer side; the inner side of the fore femora and tibiæ are clothed with yellowish pubescence.

The female of *C. tibialis* have the third to sixth joints of the antennæ not so strongly notched at the apex, the head without the smooth spot at the base of the antennæ and the fore tibiæ without long pubescence. The species which I have named *C. tibialis* (Trans. Ent. Soc. Lond. 1871) differs from *C. assamensis* in having the head less thickly punctured, and in having the mesothoracic epimera clothed with white pubescence.—*C. W.*

This species is found in Assam, where it is employed as a vesicant, and probably also in Upper Bengal. The two forms or species are collected together indiscriminately.

NEPAL BLISTER FLY, *Lytta Nepalensis*, Hope; black, head rufous, antennæ filiform, tibiæ not hairy behind, elytra broader towards the apex.—*Epicauta nepalensis*, Hope, Gray's Zool. Misc. p. 32.

Cantharis nepalensis, C. Waterhouse, Trans. Ent. Soc. 1871, p. 405.

Closely allied to *C. ruficeps* of Illiger, but is to be distinguished from it by the deeper red colouring, and strong punctuation of the head, and by the elytra being distinctly broader towards the apex.

The head is dull dark red, not very thickly, but somewhat strongly punctured; the clypeus is almost entirely black, as are also the labrum and other parts of the mouth. The antennæ are filiform, very slightly pubescent; the first joint short, the second very short, the third the longest, the fourth to seventh equal, the eighth to tenth rather shorter, the eleventh a little longer than the seventh. The thorax is subquadrate (contracted in front), thickly and distinctly punctured, less closely, and rather more strongly on the disk; the fore part is slightly impressed on each side, there is a faint longitudinal line on the disk, and a deep fovea in the centre of the posterior margin. The elytra somewhat broader towards the apex, where they diverge, each rounded at the apex, the whole surface distinctly punctured. The under side of the insect is entirely black, clothed with long black pubescence; legs simple; the anterior tibiæ not dilated, nor clothed with long hair. Length $6\frac{1}{2}$–$11\frac{3}{4}$ lines.—*C. O. W.*

Included in the Pharmacopœia of India, in note, where it is stated to be one of the vesicants employed.

Mr. C. Waterhouse has also described a black species from Allahabad, in the 'Transactions of the Entomological Society,' which is probably also employed as a vesicant. It is named by him *Cantharis hirtipes*, and is very closely allied to *C. nepalensis*, but larger and more cylindrical. Length $12\frac{1}{2}$ to $13\frac{1}{4}$ lines.

Red-breasted Blister Fly, *Lytta ruficollis*, Fabr.; golden green, thorax rufous, attenuated anteriorly.—Fabr. Ent. Syst. 1. p. 85; Oliv. Ent. iii. t. i. f. 6. *L. syriaca*, Fuessly, Arch. t. 30, f. 1. *L. tenuicollis*, Pall. Ic. p. 102. t. E. f. 35.

Native of the East Indies. A little smaller than the common blistering-fly. Antennæ filiform, bronzed. The head is inclined, of a golden green, with the eyes black. Thorax rufous, attenuated anteriorly. Elytra flexible, minutely punctulate, golden-green. Body beneath golden, subtomentose. Tibiæ dark ferruginous. Feet coppery green.

Christison states that this species is employed in the Deccan.

Yellow Deccan Blister Fly, *Lytta Rouxii*, Castelnau; black, above and below clothed with short golden pubescence, elytra and tibiæ pale brownish-yellow. Length 6–$8\frac{1}{2}$ lines.—Castelnau, Hist. Nat. des Insectes, ii. p. 274.

Male.—The head is moderately thickly and strongly punctured, with a slight impression on the forehead; at the base of each antenna is an ovate smooth spot, impressed in the middle; the front of the head between these spots also is smooth. The first, second and upper edge of the third joints of the antennæ are pitchy-red, the third and sixth joints are triangular, the seventh joint very slightly so, the eighth to eleventh cylindrical. The thorax is black, subquadrate, finely punctured, a trifle longer than broad, suddenly contracted in front, longitudinally finely canaliculate on the disk; the elytra are very little broader at the apex than at the base, very slightly diverging at the apex, where each elytron is rounded; anterior femora not furnished with any special silky spot at the base; the basal joints of the tarsi have a tendency to reddish-yellow, especially those of the fore-legs.

Female differs from the male in having the third to sixth joints of the antennæ not dilated, and the head is punctured almost to the front margin, without the smooth spot at the base of the antennæ.—*C. O. W.*

Found in Bombay, and, according to specimens in the Museum of the Pharmaceutical Society, in the Deccan. These specimens are labelled *Cantharis aurata* and *C. ruficollis*; but the two bottles of specimens appear to be specifically the same. They are believed to be commonly employed as vesicants in that part of India. Mr. C. O. Waterhouse refers these specimens to the species above named, but adds, "Castelnau's description does not mention that the thorax is black; his specimen may have been immature, but should the insect above described prove distinct, the name *C. aurulentus* might be given to it."

Under the name of *C. aurata*, Dr. Christison mentions a species which is used in the Deccan. It may be the above.

Andol-Andol. Dr. Roxburgh Wylie, in a recent communication to the *Australian Medical Journal* (March, 1871), states that "during my three and a half years' residence in the island of Java, Dutch East Indies, I found that a vesicant was extensively used in medical practice, the name or existence of which I had never before heard. Like cantharides, tinct. andol-andol is obtained from a fly. It is found in China in great abundance. It is of a dull, dirty leaden colour, about twice the size of the Spanish fly, and in general appearance not unlike a large Australian blow-fly. The tincture of andol-andol is most convenient as a blistering fluid, being painted on the part to be vesicated, just as tincture of iodine is used. It dries on the skin in a few seconds after application, and vesicates most effectually in from three to four hours.

"Before applying it, however, the skin of the part to be blistered should be washed, first with soap and water, and then with common vinegar. Ever since I first heard of it, until now, I have used tinct. andol-andol and never found it fail. It can be had of any chemist in Java."

Of course it would be only speculation to name any insect as the source of this vesicant, but the probability is in favour of its being some species of *Cantharis*. The only one specifically named by Dr. Porter Smith in his 'Chinese Materia Medica,' is *C. erythrocephala*, which he says has been met with in Shanghai and Chefoo. It is possible that the andol-andol may be the *Huechys sanguinea* hereafter to be alluded to. If so, its mention here is premature.

(To be continued.)

CROTON CHLORAL.

The following particulars concerning a new organic compound, to which Dr. Liebreich has given the above name, have been furnished to the *Medical Times and Gazette* by Dr. Julius Althaus:—

"I think it will be interesting to the readers of your journal to hear that Dr. Oscar Liebreich, of Berlin, to whom we owe that valuable therapeutic agent, hydrate of chloral, has lately been engaged in investigating the physiological and therapeutical properties of a new organic compound called croton-chloral, which is formed by conducting chlorine gas into allylene. A peculiar action of this new substance upon animals is, that at first a high degree of anæsthesia in the head is produced, while sensibility in the other parts of the body remains intact. The second stage is, that the spinal cord loses its function, and reflex excitability is everywhere extinguished. During that stage both pulse and respiration remain unchanged. The third stage, which is induced by large doses, is characterized by paralysis of the medulla oblongata and death. Animals may, however, be kept alive by artificial respiration, because the function of the heart is not interfered with; while the ultimate effect of hydrate of chloral is to paralyse the heart. The first therapeutical experiments with the new compound were made in the University Clinique of Berlin. Complete anæsthesia of the fifth pair of cerebral nerves was produced in a child, reflex excitability in the other parts of the body continuing unchanged at the same time. Pulse and respiration remained exactly the same during the whole time of the narcosis. Further experiments upon insane patients showed that we possess in croton-chloral a remedy by means of which the brain may be profoundly narcotized without any other functions being disturbed, while by chloral not only the brain, but the nervous system altogether, is rendered anæsthetic, and the heart's action is diminished, which must always constitute a source of danger. Croton-chloral, therefore, promises to produce all the good effects of hydrate of chloral without any drawback being attached to its judicious use. Its apparently specific effects on the fifth pair of cerebral nerves makes us indulge the hope that it may perhaps be found useful in that most intractable affection, true tic-douloureux, or epileptiform neuralgia of the face."

SYRUP OF SENNA.

BY J. B. MOORE.

This syrup, which was officinal in the U. S. P. of 1850, was omitted in that of 1860, the authors, perhaps, thinking that its place might be supplied by the fluid extract; but, as the syrup has been so long known and used, not only in professional but also in domestic practice, there still exists for it a lingering demand, which is likely to continue. To supply this demand the pharmacist is compelled to keep the syrup constantly on hand; and, as the formula of the U. S. P. of 1850 yielded rather an uncertain preparation, which was very liable to spoil if long kept, I thought I would offer a formula for its preparation, which I have used for several years, and which will afford a reliable and permanent syrup. As an evidence of this, I have samples of it which have kept for nearly three years unaltered. The demand for the syrup in some localities being limited, and the fact of its being an unstable preparation as made by the late officinal formula, some pharmacists have been led to the habit of making it, in small quantities, as needed, from the fluid extract; but this practice should not be encouraged, and it is only when the pharmacist makes correctly his own fluid extract, and is sure of its reliable quality, that this mode of preparing the syrup should ever be employed.

The following is the process which I have adopted:—

℞.	Pulv. Sennæ, No. 60	℥ij troy.
	„ Fœniculi, No. 60	℥j „
	Sacchar. alb., sifted	℥ix „
	Glycerinæ	f℥iv „
	Alcohol. dil.	sufficient quantity.

Mix the powders, and, having moistened the mixture with dil. alcohol, pack it firmly in a glass funnel prepared for percolation, and gradually pour diluted alcohol upon it until sixteen fluid ounces are obtained, or until the mixture is exhausted. Set aside in a shallow dish, in a warm place, the first four fluid ounces which pass, to evaporate spontaneously to two fluid ounces. To the remainder of the percolate add the sugar, and evaporate it in a water-bath at a temperature not exceeding 160°, with frequent stirring, until the whole measures, when cold, ten fluid ounces. To this add the glycerine and reserved portion, mix well and strain through muslin.

If the percolation is managed with care, the reserved percolate will contain at least four-fifths of the active properties of the senna and the aromatic qualities of the fennel. This, then, being evaporated spontaneously, and the remaining portion protected by the sugar from the injurious effects of the atmosphere during the concentration, furnishes a syrup embodying the virtues of the senna and fennel unimpaired.

One serious objection to the process of the U. S. P. 1850, was the prolonged exposure to heat necessary to reduce the syrup to the "proper consistence," during which a great portion of the volatile oil of the fennel must have been dissipated, and the purgative properties of the senna in a measure diminished, while at the same time its griping tendency was promoted.

This same objection applies with double force to the present British process, presented in the last edition of the U. S. Dispensatory. In that process about one hundred fluid ounces of infusion are directed to be reduced, by evaporation, to ten fluid ounces. It can well be imagined what influence this torture, as it were, would exert upon the medicinal properties of the senna, if they are at all vulnerable to the effects either of heat or atmospheric oxygen.

Another very objectionable feature of the British syrup is that of its strength, which is about four times as great as that of the U. S. P. 1850. Upon this point Dr. Wood, in his comments upon the process in the U. S. Dispensatory, very properly makes the following remarks:—"The present British syrup, which has superseded the former syrups of the London and Edinburgh colleges, differs from them, as well as from that of the U. S. P. of 1850, very greatly in strength, so that in prescribing it physicians accustomed to the doses of the former syrups must be on their guard not very seriously to overdose their patients." These remarks are equally applicable to its use in domestic practice; and, since it is chiefly given to children, its administration in excessive doses might be attended by mischievous results.

As the British process is the only one that the late edition of the U. S. Dispensatory offers to American pharmacists for their guide in the preparation of this syrup, and as it has an established reputation they are obliged to keep it in stock, I think it highly important that it should be reinstated in the next edition of our Pharmacopœia, and a good working formula given, which will yield a reliable and at the same time a *permanent* preparation, corresponding in strength with that of the U. S. P. 1850.

The proportions of senna and fennel, in the formula given above, correspond precisely with those of the formula of our late Pharmacopœia; but in the latter process the volatile oil of the fennel was only partially extracted by the aqueous menstruum, and a portion even of that must have afterwards been lost in the evaporation of the syrup. This, therefore, necessitated the employment of a large excess of the fennel.

Now, since in the process proposed by me the aromatic properties of the latter are entirely extracted, and there is but slight if any loss by subsequent evaporation, I think that the quantity of the fennel might with propriety be reduced one-half, and still be sufficient to answer all purposes for which the aromatic is employed, without in the least impairing the virtues of the syrup.

It will be observed that in the above formula I have employed diluted alcohol as the menstruum in the place of water, which has heretofore been exclusively used. This has not been done unadvisedly, but from a strong conviction that the alcoholic menstruum possesses superior advantages over that of the aqueous one; for by means of it there is obtained directly, by the process of percolation, a more highly concentrated solution, obviating the long and tedious application of heat necessary to reduce the aqueous solution to a proper strength, thus more than counterbalancing whatever advantages, if any, therapeutically, the aqueous may have been supposed to possess over the spirituous solvent.

It has doubtless been owing to the tedious and inefficient methods heretofore in vogue in the manufacture of this syrup that this formula has been discarded from our Pharmacopœia, and to its partial disuse in professional practice. It is certainly, however, when properly prepared, an efficient, useful and convenient preparation for children, for whom it was originally intended; and if a reliable and satisfactory formula, such as we present, should be adopted in its manufacture, its restoration to its former place in professional favour will doubtless follow.—*Amer. Journ. Pharm.*

THE MOST IMPORTANT METHODS OF DETERMINING ARSENIC VOLUMETRICALLY.

BY E. WAITZ.*

The author has investigated with great care the different methods for determining arsenious acid, viz., 1st, by means of free iodine; 2nd, by means of dipotassic dichromate; 3rd, by means of potassic permanganate; as well as the method for estimating arsenic acid by means of uranic acetate.

The iodine method depends, as is well known, upon the conversion of arsenious into arsenic acid in alkaline solution. In an acid solution arsenious acid can exist in the presence of iodine or chlorine, and is only partly converted into the higher oxide. The alkali must be in the form of a carbonate, for a caustic alkali combines with the iodine. The author's experiments show that normal sodic carbonate fixes iodine, but that the acid carbonate does not; a solution saturated in the cold should be used. This only confirms the previous observations of Fresenius. On employing a standard solution of arsenious acid in hydrochloric acid, the free acid has first to be neutralized by means of caustic soda or acid sodic carbonate. With an excess of this latter salt, good results were obtained.

Experiments made with a view of converting precipitated arsenious sulphide into arsenious acid by the action of an ammoniacal solution of silver nitrate upon the sulphide dissolved in ammonia, as well as by means of freshly precipitated bismuthous hydrate, and of substituting in this manner the trisulphide—which can be obtained in a state of great purity—for the trioxide, were unsuccessful, as the reaction is never quite complete, owing to the formation of sulpho-salts of silver and bismuth.

The method first proposed by Kessler † of determining arsenious acid in an acid solution by means of dipotassic dichromate, and standardizing back by means of a ferrous sulphate solution, gave good results. Excess of hydrochloric acid has to be avoided. Kessler succeeded in utilizing arsenious sulphide by treating it in a hydrochloric acid solution with mercuric chloride, a saturated solution of which converts the sulphide slowly at the ordinary temperature, more rapidly on the application of a *gentle* heat, into the trioxide. The reaction is over when the mass has become white. The author's experiments show further that the mixture of trisulphide and sulphur which is obtained when a solution of arsenic acid is precipitated with sulphuretted hydrogen, cannot be converted directly into arsenious acid by digestion with mercuric chloride, on account of the dense nature of the precipitate, but that it is readily acted upon, after dissolving out the trisulphide by means of dilute ammonia and reprecipitating with hydrochloric acid.

The oxidation of arsenious into arsenic acid by means of potassic permanganate is never perfect,* and a volumetric method based upon this reaction was found by the author to be most untrustworthy; but by adding excess of permanganate—more than double the amount required according to theory—and standardizing back with a solution of ferrous sulphate, very accurate results were obtained.

The volumetric determination of arsenic acid by means of uranic acetate in the presence of free acetic acid and an alkaline acetate, did not yield trustworthy results.

THE ACTIVE PRINCIPLE OF POLYGONUM HYDROPIPER.

BY C. J. RADEMAKER, M.D.

Having seen hydropiper frequently used, both in the form of tincture and fluid extract in amenorrhœa and other uterine disorders, with very satisfactory results, I was induced to make a chemical examination of this drug.

In order to obtain the active principle or principles, the following processes were resorted to:—

Experiment 1*st*.—Two pounds of the herb were exhausted with diluted alcohol, the alcohol distilled off by means of a water-bath, the remaining liquid was evaporated to about one-third of the original bulk; during the evaporation a considerable amount of resinous matter was precipitated, the solution was filtered from the resinous precipitate and the filtrate treated with basic acetate of lead, which produced a yellow precipitate.

The precipitate produced was collected on a filter and washed with distilled water. The precipitated magma was then suspended in distilled water and treated with sulphuretted hydrogen; the resulting mixture of sulphide of lead and organic principle was treated with ether, the ether separated from the sulphide of lead and allowed to evaporate spontaneously.

The crystals thus formed were soluble in alcohol, ether, chloroform, and slightly soluble in diluted alcohol, but almost insoluble in water; when rubbed with water they become very sticky; the solution of the crystals had an acid reaction with litmus. Under the microscope they made a beautiful appearance, resembling the crystals of uric acid of human urine.

This acid may be called polygonic acid.

Experiment 2*nd*.—The filtrate from which the acid had been removed by means of basic acetate of lead, was treated with sulphuric acid, in order to remove the excess of lead, and then rendered alkaline by means of caustic potash and treated with ether.

The ether was separated and allowed to evaporate spontaneously. The mass thus left was perfectly white, neutral to test-paper, and had a bitter taste, was soluble in alcohol, ether, and the mineral acids; its solution in acids was not precipitated by ammonia, caustic potash, or sodic carbonate, nor was I able to obtain any crystals. From this I concluded that it possessed no basic properties.

Experiment 3*rd*.—One pound of fluid extract (480 grs. to the fluid ounce) was treated with hydrochloric acid, about five drops of the acid to each fluid ounce of the liquids, and then treated with ether. The ether separated and treated with basic acetate of lead, the precipitate produced was collected on a filter and washed with distilled water, the precipitated magma was suspended in distilled water and treated with sulphuretted hydrogen.

The mixture of sulphide of lead and organic principle was again treated with ether, the ether separated from the sulphide of lead, evaporated and the acid crystallized.

The crystals produced resembled those as prepared in experiment No. 1.

Chemical Properties of Polygonic Acid.—Polygonic acid, as prepared in experiments 1 and 3, has a green colour, acrid and bitter taste. It has strong acid properties, completely neutralizing bases, and uniting with them to form salts.

Aqua ammoniæ, caustic potash and sodic carbonate, added to the crystals or a solution of the crystals, produced an intense yellow colour, and the crystals were dissolved. Nitric and hydrochloric acids added to crystals or solution of the acid produced a yellow colour. Sulphuric acid added to the crystals or a solution of polygonic acid, produced a dark red colour, which gradually became black. Basic acetate of lead added to a solution of the acid or its salts, produced a yellow precipitate, soluble in the mineral acids. Nitrate of suboxide of mercury produced a yellowish-white precipitate, soluble in the mineral acids. Mercuric chloride produced a green precipitate, soluble in the mineral acids. Cyanide of potassium produced a yellow colour. Ferric chloride produced a slight dark colour. Cupric sulphate produced a slight green colour. Baric chloride, chloride of gold, nitrate of silver and chloride of platinum produced no change.

From the above it will be seen that the *Polygonum Hydropiper* contains an acid, crystallizable, colouring principle upon which the medicinal virtues of the drug mainly depend.—*Amer. Journ. of Pharm.*

THE POLLUTION OF RIVERS.

The Third Report of the Commissioners appointed in 1868 to inquire into the best means of preventing the pollution of rivers has been recently issued. It reveals an amount of injury done through the contamination of rivers by the refuse of manufacturing processes carried on in certain districts that to those who live in more favoured localities might appear almost incredible. A few years since a great and just outcry was raised concerning the then filthy state of the Thames. But those who lived on the banks of the Thames, even in its worst days, could have derived therefrom but a faint idea of what may be seen in certain rivers where a combination of manufacturing refuse and town sewage is being continually carried on. The report deals with the effects of the woollen manufacture on rivers and streams generally, including the clothing districts of the West Riding of Yorkshire, Gloucestershire and Somersetshire, the flannel trade of Wales, the blanket manufactories of Witney and Dewsbury, the worsted and rug factories of Kendal, and the carpet works of Kidderminster, Halifax, Rochdale, Durham and Wilton.

It would be out of place in this Journal to follow the Commissioners step by step through all their inquiries. It will be sufficient to epitomize the results of the investigation of one district and take it as representing approximately the results in others.

The first river reported upon is the Aire, the water of which, early in its course, is described as being excellent, though somewhat hard from its solvent action upon the mountain limestone through which it has percolated, and containing a larger proportion of organic matter than do the streams issuing from the chemically analogous chalk and oolite formations of the southern counties. The pollution of the Aire commences at Skipton; it then passes Bradley, Keighley, Silsden, Bingley, Allerton, Saltaire, Bradford, Baildon, Guiseley, Yeadon and Rawdon. By this time it has been fouled by the refuse of about 1400 factories and the sewage of more than a quarter of a million of people. Some of these factories are gigantic in their operations. At the principal one, that of Sir Titus Salt, the following quantities of material are used annually:—logwood and similar dye-wares, 320,000 lbs.; chloride of lime, ammonia and oil of vitriol, 15,000 lbs.; gallipoli oil, 40 to 50 tons; soap, 700,000 lbs.; alkali, 40,000 lbs.; coal, 14,000 tons. Some idea of the character of the influx from tributary streams may be formed from the description of Bradford Beck given by the Commissioners. They say that at the time of their inspection it left the town a black, filthy, offensive stream, even above the sewer outfall emitting offensive gases, and could scarcely be distinguished from the sewage itself. But the volume of water and the subsidence and deposit that is continually going on is so great, that at Kirkstall Bridge, above Leeds, the river is only moderately polluted.

At Leeds the river receives the sewage of a population now estimated at 270,000, and the refuse of at least 400 manufactories. The marked effect of such a mass of pollution, even upon a large river, is seen by a comparison of the analytical results yielded by samples of water taken at Kirkstall Bridge and below the Leeds sewer outfall. By the time the river has reached Kirkstall Bridge the soluble polluting materials have been increased in the form of organic carbon 3·33 times, and organic nitrogen 5·21 times, the proportion contained in the water at its source. This increase represents the addition of ·524 lb. of organic carbon and ·066 lb. of organic nitrogen to every 100,000 lb. of water. But in passing Leeds the river receives a further increase of ·601 lb. of organic carbon and ·045 of organic nitrogen; so that in regard to soluble matters the polluting effect of the single town of Leeds is not much less than the aggregate fouling produced by all the towns and factories above it. The nature of some of the filthy liquids contributed to the river by the town of Leeds may be judged of by the following result of the analysis of the esparto liquor from a paper mill:—Parts in 100,000: total solid matters, 4038; organic carbon, 938·845; organic nitrogen, 76·816; ammonia, 1·116; chlorine, 58. The corporation of Leeds have no jurisdiction over the Aire, which flows through the middle of the town. Twenty years ago the river was comparatively clean, now it is a black and filthy stream. Irrespective of the prejudicial influence its present state must exercise over the health of the town, considerable evidence was furnished to the Commissioners that a large money loss was thereby occasioned.

Ten miles below Leeds the Aire is joined by the Calder, and at the weir near the junction at the time of the inspection not only the water but the foam upon it was black. The river Calder at its source consists of water of considerable purity. But at Todmorden it is entered by the Migelden Brook, a stream so highly polluted by mine water as to be unfit for all purposes; it cannot be drunk, it is unfit for washing, and its corrosive action on iron is such as to prevent it being employed for feeding steam boilers. The acidity of this brook is equal to that which would be imparted by the addition of 8·075 parts of sulphuric acid to every 100,000 parts of water. The total quantity of sulphuric acid, in a free and combined state, was 19·48 parts in 100,000.

From the spot of the junction of the Aire and the Calder the history of these streams is but a repetition of what has already been said. Tributary streams bringing a mass of pollution, if possible, worse than that of the parent river; towns, whose inhabitants are sometimes numbered by tens of thousands, pouring in their sewage together with the refuse from chemical works, gas works, dye and bleach works and tan-yards. It will suffice to give here just a few descriptive sentences from the report. At Huddersfield "films of tar were floating on the surface of the foul stream when we saw it." Below Wakefield, "the river was turbid, and of a dark brown colour; an oily film floated on the surface, and the water emitted a mixed odour of sewage and gas tar." At Woodlesford the Commissioners were shown a large quantity of paper, which, at one time, had a delicate yellow tint, due to yellow chromate of lead, but which had been spoiled and changed to a dirty brown "by the gaseous emanations from the river water," used as a source of power in the paper mills. But, perhaps, the most striking proof consists of a facsimile of a memorandum, written with water from the river Calder. The writing is the colour of faded ink, and runs thus:—"Dedicated, without permission, to the Local Board of Health, Wakefield. This memorandum, written with water taken from the point of junction this day between the river Calder and the town sewer. Could the odour only accompany this sheet also, it would add much to the interest of this memorandum."

The report next deals with the West of England clothing districts; but, although the details as to the source and materials of pollution vary somewhat, the effects are substantially the same. Rivers and streams which, if they were preserved in a state of purity at all approaching that in which they leave the fountain head, would be a source of health and wealth to all the towns through which they pass, are made utterly useless and noxious to the general community.

In dyeing the "superfine black" cloths of the West of England, the manufacturer depends on a basis of indigo colouring, or woading, as it is called. It is incidentally mentioned, that for the dyeing of other tints, the magnificent colours now manufactured from coal tar, and known as aniline colours, are becoming gradually more employed in the place of various dye-woods. This, it is thought, will have some influence in diminishing the pollution of rivers, as it will reduce the amount of waste dye-woods which are generally cast into the nearest watercourse, and the residual liquids of the dye vats are of a less polluting character and more easily purified; since, unlike the aqueous extracts of dye-woods, they contain but very little extraneous matter either in solution or suspension.

(*To be continued.*)

THE THEORY OF DISSOCIATION.

BY A. HORSTMANN.*

The author traces the connection between the temperature, pressure, and the other elements which are of influence in a case of dissociation lately examined by H. St. Claire Deville. When steam acts upon iron in a closed vessel, there exists at every temperature a tendency towards the establishment of a constant ratio between the partial pressures of the steam and of the hydrogen which, while dependent upon the temperature, appears to be independent of the quantity of iron and its oxide, and of the absolute pressure of the gases. This may be explained by Pfaundler's hypothesis that in a given time there are as many molecules of water decomposed as newly formed. The author considers it admissible to suppose that, at the moment when these two reactions take place, a molecular compound $FeOH_2$ is formed, which, however, according to temperature or other circumstances, is immediately split up again either into $Fe + H_2O$, or into $FeO + H_2$. If such a compound were formed, then according to the mechanical theory of heat, the pressure of the hydrogen and that of the steam would increase according to the same law, which can be expressed by the equation—

$$dp = dT\frac{Q}{AT\delta v},$$

where A represents the mechanical equivalent of heat, T the absolute temperature, δv the volume of the liberated gas, Q the quantity of heat consumed in the process of decomposition, and dp the increment of pressure. δv remains the same for steam and hydrogen. Q can be computed from the heats of combustion. By the combination

of 16 pts. of oxygen with iron, are evolved 66,100 thermal units.
" " hydrogen " 59,200 "

so that the difference 6900

shows how much more heat is consumed when H_2O instead of H_2 is separated from the compound $FeOH_2$. Q, and consequently dp, is greater in the case of steam. Calling the pressure of the hydrogen p_1 and that of the steam p_2, we see that p_2 increases faster than p_1, and that the ratio $p_1 : p_2$ diminishes as the temperature rises; and this is confirmed by experiment.

If it be supposed that the quantity of heat which, during the process of decomposition, is consumed for internal work (this quantity, in the case of hydrogen, being called U, and in the case of iron U_2) does not vary with the temperature, then another equation can be deduced—

$$\log\frac{p_1}{p_2} = C - \frac{U}{AR}.\frac{1}{T},$$

in which $R = s_0 \frac{760}{273}$, s_0 being the molecular volume of H_2 or of H_2O, and $U = U_1 - U_2$. The unknown quantities C and U can be determined by two observations, and then the above equation will furnish the value of $\frac{p_1}{p_2}$ for every temperature.

The following table shows how far the experimental values agree with those obtained by calculation from the equation:—

Temperature.	Found.	Calculated.
200°	20·49	23·07
265°	13·96	14·01
363°	8·62	8·11
440°	5·75	5·75
860°	2·34	2·08
1040°	1·74	1·65
1600°	0·92	1·06

The value of U is found from the above equation to be −3900 heat units instead of −6900, which number would directly follow from the known heats of combustion of hydrogen and iron. But considering the sources of error to which the determinations of the heats of combustion, as well as the ratio $\frac{p_1}{p_2}$ are subject, we must be contented that the value of U, whether obtained directly or indirectly, has the same sign and is of the same order.

* Deutsch. Chem. Gesch. Ber., iv. 635, and *Journal of the Chemical Society.*

Do Sunflowers follow the Sun?—Many of the statements which are demonstrated in the progress of science to be erroneous have, as a foundation, a substratum of fact. The popular notion that the sunflower follows the sun in its course has been often combated and contradicted, but, according to Mr. J. A. Allen, one species at least of the genus *Helianthus* has this peculiarity. He says, "It is a popular belief that the sunflower always turns its flowers towards the sun, but in reality, so numerous are the exceptions to this rule in our garden sunflowers and in our common [American] wild species of the East, that few observing people regard it, doubtless, as otherwise than an idle whim. With many of the prairie sunflowers, however, the facts are different; especially is this so in the case of *H. rigidus*. Morning after morning, at flowering time, the heads of this species may be seen bending gently towards the east; they are erect at midday, and at evening gracefully droop towards the west. This continues, day after day, for weeks, with surprising regularity and uniformity; later, however, the stems grow rigid, and remain nearly vertical. In this case, at least, the popular notion referred to above seems well founded."—*Gardeners' Chronicle.*

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 25, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PRESCRIBING AND DISPENSING.

A brief communication published in the "Correspondence" of last week's Journal naturally directs our attention to the very important subject above indicated, and induces us to make sundry categorical remarks thereupon. We are content to begin with the prescriber's aspect of the question, and may, we suppose, assume his dictum to be that a prescription, once committed to paper, is to be "accurately" dispensed, without jot or tittle of change. How dubious soever the caligraphy, how absurd soever the errors, the dispensing must be "accurate," or the dispenser has failed in the fulfilment of his duty. This sort of Medic and Persianic rule, which obtains with many if not most physicians, arises, we must assume, from an idea that all the "mind" is on one side, and all the "matter" on the other. If such were positively and actually the case, we might fitly stick to the rule unswervingly, and all would be well. But we know that it is not so. In taking the dispenser's aspect of the question, we find that mental as well as physical powers have to be exercised on many occasions to a very considerable extent. Prescriptions are sent so cloudily written that it is next to impossible to decipher them; so funnily constituted as to result in a chaos of chemical combinations; and so faulty as to quantities that "accuracy" in the dispenser would inevitably result in death to the patient.

That these three sins in prescribing are committed by physicians daily and hourly, no one who has had any experience in the ways and means whereby physic is imparted to the public will attempt to deny. The evil is particularly patent, but the remedy is equally plain. It is manifestly the duty of physicians to pay more attention to caligraphy, to chemical combinations and to correct quantities. But it is as clearly and positively the duty of the dispenser to communicate with the prescriber in all cases of doubt and difficulty, whether they have reference to any one or all of the errors above indicated. It is by no means the "whole duty" of a dispenser to decipher one-half of a prescription and to imagine the rest, to remedy or supply chemical errors or deficiencies, or to reduce a dangerous dose to the innocuous point. The prescriber and dispenser may, and should, always work harmoniously; for if the latter invariably adopts the plan that we have recommended, the former will be very glad to acknowledge and appreciate that valuable sort of discretion that can, in pharmaceutical work, alone constitute the security of the physician.

THE POPPY CROP IN BEHAR AND BENARES.

We learn that the poppy crop of the past season in the Behar and Benares agencies has suffered much from excessive rains and an unusually severe visitation of blight; this blight is reported "to have been quite different from that hitherto known in Behar, which affects only the small stunted poppy, when dried up by the hot winds in March. This year the finest and strongest poppy has been attacked. It appears first to have manifested itself at the beginning of February, when the leaves of the plant began to wither and turn black, the plant eventually dying. The late-sown plant has perhaps suffered the most severely, whole fields of this having been destroyed; but the damage done to the early-sown plant has also been very considerable, while the portion that seemed to have escaped the blight has not actually been free from its effects, the capsules of such portions having dried up after two or three incisions, instead of standing four, five and six, the produce of each incision being at the same time small."

So great has been the effect of this visitation, that only 41,000 chests of opium are expected as the results of the harvest, instead of 55,724 as originally estimated. No satisfactory conclusion can be arrived at in India as to the cause of these ravages; the popular notion amongst the natives, however, "is that the excessive rain of October washed a good deal of the strength of the soil out of the land, and that the unusual heat in the early part and middle of February, together with the cloudy weather and easterly winds which prevailed, have been the main cause."

It is satisfactory to know that the Indian Government, both in India and at home, are taking steps to ascertain, if possible, the cause of this blight, the result of which we hope may be successful.

AN AMERICAN ENIGMA.

We have no desire just now to take part in the discussion of the question as to whether man has been developed from any other form of life. We simply wish to furnish an illustration of how easily he may be changed into something else—at least in name—under the printer's care, assisted by the fostering influences of illegible manuscript and inefficient supervision. The *Leavenworth* (Kansas)

Medical Herald and Journal of Pharmacy informs its readers that at the late meeting of the American Pharmaceutical Association at St. Louis,

"The Executive Committee sent in the following names as honorary members of the Association: Prof. Bedford, of London; Prof. H. B. Brady, of Newcastle-upon-Tyne, England; Prof. Attfield, London; Prof. De Weig, Hague, Netherlands; Leon Lourteman, Augusta Delamaitre, A. Chavallier, Paris, France; Prof. Adolph Duplous, Germany; H. Ludwig, Jena, Germany; Anthony Von Waldhein, Viena, Austria."

A key to the above riddle, with the exception of the fourth name, which appears to be meant for Dr. J. E. De Vry, may be found in a previous number of this Journal, p. 390.

THE ROYAL INSTITUTION.

The following lecture arrangements at the Royal Institution for 1871–72 are announced:—

Prof. Tyndall, LL.D., F.R.S.—Six Christmas lectures (adapted to a juvenile auditory) "On Ice, Water, Vapour and Air," on December 28, 30, 1871; January 2, 4, 6, 9, 1872.

Dr. W. Rutherford, F.R.S.E.—Ten lectures "On the Nervous and Circulatory Systems," on Tuesdays, January 16 to March 19.

Prof. Odling, F.R.S.—Ten lectures "On the Chemistry of Alkalies and Alkali Manufacture," on Thursdays, January 18 to March 21.

W. G. Clark, M.A., Vice-Master of Trinity College, Cambridge, late Public Orator.—Six lectures "On the History of Dramatic Literature, Ancient and Modern," on Saturdays, January 20 to February 24.

Moncure D. Conway, Esq.—Four lectures "On Demonology," on Saturdays, March 2 to 23.

Dr. W. A. Guy, F.R.S.—Three lectures "On Statistics, Social Science and Political Economy," on Tuesdays, April 9, 16 and 23.

Ed. B. Tylor, Esq., F.R.S.—Six lectures "On the Development of Belief and Custom amongst the Lower Races of Mankind," on Tuesdays, April 30 to June 4.

Professor Tyndall, LL.D., F.R.S.—Nine lectures, on Thursdays, April 11 to June 6.

R. A. Proctor, Esq., B.A., F.R.A.S.—Five lectures "On Star Depths," on Saturdays, April 13 to May 11.

Prof. Roscoe, F.R.S.—Four lectures "On the Chemical Action of Light," on Saturdays, May 18 to June 8.

The Friday Evening Meetings will commence on January 13th.

The Friday Evening Discourses before Easter will probably be given by Mr. W. R. Grove, Q.C., the Archbishop of Westminster, Professors Odling and Humphry, Dr. Gladstone, Messrs. C W. Siemens, R. Liebreich and John Evans and Professor Tyndall.

We have great pleasure in recording some further additions to the list of honours that have been conferred upon gentlemen more or less intimately connected with pharmaceutists. At the Court of Common Council of the City of London held on Thursday last, Mr. Deputy Elliott, in proposing a resolution that the thanks of the Court should be awarded to Mr. Alderman Dakin, the retiring Lord Mayor, read a letter that had been received from Mr. Gladstone, offering him, in the name of her Majesty, the honour of knighthood. At Richmond (Yorkshire), Mr. T. Thomas Thompson, Pharmaceutical Chemist and Local Secretary, has been re-elected Mayor.

Among the subjects announced for the Wednesday Evening Meetings of the Society of Arts before Christmas are, "Sewage as a Fertilizer of Land and Sand as a Purifier of Sewage," by Mr. J. Bailey Denton, on December 6; "Observations on the Esparto Plant," by Mr. Robert Johnston, on December 13; and the "Study of Economic Botany, and its Claims Educationally and Commercially Considered," by Mr. James Collins, on December 20.

An experiment in illumination is now being made at the Crystal Palace, which it is said bids fair to exercise an important influence upon our present methods of obtaining artificial light. In the oxyhydric light advantage is taken of a new method of obtaining oxygen, from manganate of soda, by heating it alternately in an atmosphere of steam and air. It is stated that by this means oxygen can be produced very cheaply. Novel arrangements of burners are used, and the light produced by them is of great brilliancy and steadiness.

The *Lancet* mentions a rumour that in the approaching session of Parliament Mr. Muntz will introduce a Bill on the Adulteration of Food, which will be free from the objections of the unsuccessful Bill of last session. It is also said that the Home Secretary will propose legislation upon the same subject.

The Royal Society's gold medal has been awarded to Dr. Stenhouse, a chemist whose name is well known for his investigation of several drugs amongst other important contributions to science.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Third General Meeting of the Society was held on November 9th; the President, Mr. E. Davies, F.C.S., in the chair.

The following donations were announced:—current numbers of the Pharmaceutical Journal, and Liverpool Medical and Surgical Reports, October 1871, by Drs. Braidwood and Harrison.

The President called attention to formulæ for coloured fires, by J. R. Bramschweiger, published in the *Journal of the Chemical Society* for October, which he had prepared and tried. They were free from the danger of spontaneous combustion and obnoxious smells. The shellac used in the preparation only required to be very coarsely powdered. The following are the forms:—

Red Fire, 9 parts Nitrate of Strontia.
3 parts Shellac.
$1\frac{1}{2}$ parts Chlorate of Potash.

Green Fire, 9 parts Nitrate of Baryta.
3 parts Shellac.
$1\frac{1}{2}$ parts Chlorate of Potash.

Blue Fire, 8 parts Ammonio-Sulphate of Copper.
6 parts Chlorate of Potash.
1 part Shellac.

Mr. Alfred H. Mason, F.C.S., observed that before the reading of the paper for the evening, he wished to call attention to the name of one intimately associated with the subject, he meant Dr. Richardson. He stated that this eminent man, who has done so much to relieve human suffering, is now engaged trying to prevent, if possible, pain to animals when being slaughtered. Mr. Mason described the experiments Dr. Richardson had tried, and expressed a hope that he would be successful in his efforts.

Mr. Alfred E. Tanner then read a paper on "Nitrite of Amyl," which is printed at p. 421.

The President said that he felt a great interest in the subject, as many years back he had experimented with nitrite of amyl, and had experienced from it some very singular effects. After inhaling from a few drops on blotting-paper a peculiar sensation was experienced, a sense of dizziness, singing in the ears, the face flushed and veins throbbed until the paper was removed, when the effects disappeared. It appeared, however, to be almost without action on the lower animals. He thought that Mr. Tanner's modesty scarcely allowed him to claim the merit due to his discovery of a much improved method for making this substance, as, in his opinion, the author had shown sound chemical knowledge, and great perseverance and skill. The paper was valuable, as containing the result of original research, and he trusted that the other members would be induced to investigate new products which came under their notice, and communicate their discoveries to the Association.

Mr. Mason fully endorsed the remarks of the President, and said they were much indebted to Mr. Tanner for his important communication to the Association in the valuable paper they had just heard. The method of manufacture employed by Mr. Tanner was a good suggestion; it was rather remarkable that the same idea had occurred to Professor Maisch, of Philadelphia, and evidenced the more honour due to Mr. Tanner, in that he had successfully brought about the result anticipated. Mr. Tanner had reminded them that it was of the highest importance that these sensitive therapeutical agents should be employed in as pure a state as possible, it was therefore of importance that the pharmacist should have some reliable test; he agreed with Mr. Tanner that the boiling-point was a guarantee of purity, but thought it desirable that the boiling-point and the specific gravity should be taken together; he did not think fractional distillation was a reliable test, it could not be expected that an homologous compound like amyl nitrite would be so stable as a body having a simple composition. Ethyl nitrite distils without change, but when we get up to amyl we find the nitrite decomposing.

Mr. Tanner said Mr. Maisch published his paper some twelve months subsequently to his (Mr. Tanner's) discovery. He also observed that he used anhydrous amylic alcohol in preparing the nitrite of amyl; the process had failed when anhydrous spirit had been employed.

Dr. Symes, in proposing a vote of thanks to Mr. Tanner, said the subject was a very desirable one to know about. He thought the boiling-point was a sufficient test of purity for medical purposes, and fully appreciated the value of Mr. Tanner's discovery, as he had prepared it by the old process, and it was important to have a process by which any one with an ordinary amount of chemical knowledge might produce it. If pharmaceutical and chemical products were generally prepared instead of being purchased, much additional knowledge would be gained, and the scientific character of the pharmacist greatly elevated.

BRISTOL PHARMACEUTICAL ASSOCIATION.

Friday, November 10, 1871; a General Meeting of the Association was held this day, Mr. W. W. Stoddart in the chair.

The Chairman briefly introduced the newly elected President, and expressed the gratification he felt in resigning the post he had held for two sessions to one who would adorn it so well as Mr. Townsend.

Mr. Charles Townsend, having taken the chair, said the first duty he had to perform was a very pleasing one, namely, to distribute the prizes to the successful candidates among their students of the last session.

Mr. Arthur Little had earned—

1st prize, advanced grade, Inorganic Chemistry.

1st prize, elementary grade, Organic Chemistry.

1st prize, advanced grade, Structural and Physiological Botany.

Mr. Little had also been awarded the gold medal of the Science and Art Department of the Committee of Council on Education for his proficiency in this last subject, viz. "Structural and Physiological Botany." This was a great distinction, and an honour at once to himself, to his teacher and to the Association of which he was a member.

Mr. George W. Tamplin had earned—

1st prize, advanced grade, Organic Chemistry.

A prize, elementary grade, Systematic and Economic Botany.

Mr. Charles Bennett had earned—

2nd prize, elementary grade, Inorganic Chemistry.

2nd prize, elementary grade, Organic Chemistry.

A prize, elementary grade, Structural and Physiological Botany.

Mr. Ernest Samson had earned—

1st prize, elementary grade, Organic Chemistry.

Mr. Charles E. Bishop had earned—

2nd prize, advanced grade, Inorganic Chemistry.

Mr. Baynham had earned—

A prize, elementary grade, Systematic and Economic Botany.

The prizes having been distributed, the President delivered the following address:—

Ladies and Gentlemen,—For the first two years of its existence the Bristol Pharmaceutical Association has been under the presidency of a gentleman so well known and highly esteemed throughout the kingdom for his varied and abundant talents, and for his accurate knowledge of the several sciences immediately connected with pharmacy, that *any one* may be excused for feeling considerable diffidence in occupying the post of his successor; and as I make no claims to be considered a *scientific* president, I must rely upon your kindness to receive the few remarks I have to make this evening with some little indulgence.

We commence to-day the third session of our Association; it has been upon its trial for two years, and the time is fitting to ask what has been accomplished, in what respects our objects have succeeded, and in what respects we have failed?

That there has been conspicuous success is evident enough from the pleasant duty I have had to perform this evening; and those of you who have given the greatest attention to, and felt the warmest interest in our Association, well know that there have been very many failings also.

We have in our city about eighty members of our profession, and it is gratifying to notice, that of this number no less than fifty-seven were last year associated with our Society; and I venture to hope that all, or nearly all the rest, will come in and assist us in the work of establishing in Bristol a thoroughly efficient school of scientific pharmacy. This, then, is one element of success; there is an increasing interest in the objects we have at heart on the part of those actually in business, and who, I would have all the students to remember, can themselves derive but small benefit from our labours.

It is for those who, as one by one we grow old and weary in the work, come in and fill our places, to reap the fruits of labours which for thirty years have been incessant, and which now we are endeavouring to carry home to all.

To a large extent we may consider also that the provision which has been made for scientific instruction in the past two years has been successful; no society can have two more able professors than Messrs. Coomber and Leipner, the character of their instructions and their value to those who are really in earnest in availing themselves of their lectures may be gathered from the high position which several of our students have taken. During the present year we are able to supplement the two courses of lectures on Organic and Inorganic Chemistry by Mr. Coomber, and the course of lectures on Botany by Mr. Leipner, by what, I cannot but say, I think of equal value and importance. I refer to the course of lessons on the Chemistry, Botany, and Materia Medica of the Pharmacopœia, which has so kindly been undertaken by your late President, Mr. W. W. Stoddart.

I should feel that I was utterly failing in my duty if I did not express the deep obligation we are all under to one of our best and kindest friends, and I must ask those of our students who are availing themselves of Mr. Stoddart's most able and voluntary services, to reward him in the way which I am sure he will deem the best and most congenial, namely, by a *patient, diligent and earnest* attention to his valuable instructions.

We have all felt the interest that has attached to the public monthly lectures given during the past session; they have been worthy of a scientific society, and in every way successful; and I am pleased to tell you that several of the gentlemen who assisted us last year (including Dr. Tilden) have again yielded to the winsome wiles of our honorary secretary, and we may look forward with pleasure to another opportunity of sitting at their feet to learn.

Now, gentlemen, I must unwillingly turn to the other side of the picture and point out what we feel are some of the failings of the past, doing so only that I may stimulate each one of us to help to remove them in the future. And the first difficulty which meets us, one very serious in its aspect, is the large proportion of students who fail to pass the Preliminary examination.

An immediate remedy for this is out of our power, but to those pupils who have suffered from a defective early training—possibly and probably from no fault of their own—I would say, put your shoulders to the wheel at once, and do not rest contented until you have fairly crossed the bridge and acquired that which you can readily attain if you are in earnest in seeking it. And as to those of us who are employers, it is clearly no part of our duty to turn schoolmasters; with the materials we now have we must do the best we can. I cannot but think it will be the bounden duty of every pharmacist in future *absolutely to refuse* to accept any pupil who is not able when he is apprenticed to pass, or who has not passed, this examination.

It must not be supposed that we, as pharmacists, are singular in this matter, the same complaint is made by the examiners for all the professions and for the Civil Service; and it is perfectly astounding to find the number of candidates presenting themselves whose arithmetic is a dreamy chaos, and whose spelling might be either Welsh or Chinese, but is certainly not English.

It is to be hoped that the golden age is dawning, and that the first streaks of day, ushered in by the Education Bill, will by-and-by open out into a noon of bright and sunny light for all.

Passing on, I consider we have in the past failed to some extent in calling out and *sustaining* the personal interest of the students in our work, and I think this, in great part, arises from the want of a museum and library. Time and money can alone remedy this, and the subject is now occupying the very earnest attention of the Council; and, with the hearty and practical support of all our brethren, we hope, at no distant day, to have a school of pharmacy in Bristol, possessing a museum and library worthy of the chief city of the west. I should like to see attached to it a reading-room *of our own*, open every day, *comfortable, cheerful* and *attractive*, where all could meet and obtain, by mutual contact and pleasant intercourse, that personal interest and acquaintance which is the surest remedy for all jealousies and disagreements.

Another source of regret, which we venture to hope may pass away in the future, has been alluded to in the admirable report drawn up by Mr. Schacht, and published in the PHARMACEUTICAL JOURNAL in July last, namely, the deficiency of practical papers supplied by members at the evening meetings for discussion.

I think this may be, and ought to be remedied and I would venture to suggest the plan which I observe has been adopted by the Philadelphia College of Pharmacy,—"The appointment of a small committee, whose duty it shall be to propose subjects for discussion whenever there is a lack of material contributed by members." There are many of our members who have been conspicuous by their silence, and many others who have been equally conspicuous by their *absence*, and I would urge upon both classes to relieve the cares of the Council by their friendly and frequent aid and presence.

I fear, ladies and gentlemen, you will think I am in a grumbling humour, but you know that an Englishman is essentially a "growling animal," and if you will permit me one more growl, I will have done with this part of my subject. This time I complain for *others;* for those whose interest and training we have at heart, and for whose especial benefit we form our various local associations and schools.

"I have no time," is the not altogether unreasonable wail of assistants and apprentices alike; and it must be conceded that in many instances, the bane of our business, the great hindrance to progress and to study, is the long, and, as *I* believe, the *needlessly* long hours of labour.

No rule can possibly be laid down for uniform closing, and many difficulties lie in our way; nevertheless, I am disposed to think that much remains to be done, and that with an earnest and united effort, the hour of closing may be fixed at a point at which all the strength and energy of the human frame are not absolutely exhausted. I venture to suggest that our Hon. Secretary should call an early meeting of our members specially to consider this subject, and, if possible, to come to some resolution which shall relieve our pupils and assistants a little earlier than is generally the custom at present. I do not consider that in the majority of cases, any of our establishments need be kept open after eight o'clock, and that in very many the workers may be, and ought to be relieved an hour earlier than this.

I have thus endeavoured to review the past history of our Society, and you must all feel with me that the balance is largely on the side of progress, and that we have cause for congratulation that in so short a time so much has been accomplished. Let me say to our students: throw your hearts into your work; do not be satisfied with the acquirement of just as *little* knowledge as will enable you to *scrape* through your examinations. You have a noble calling, and the widest range of science lies before you. In every shady glen and mossy bank there are fascinations for your minds; all nature is at your feet, every clime contributes something to your material for study and research; nothing is hidden from the earnest seeker in the mines in which you labour; every leaf and stem has lessons for you; it is yours to test every principle at work in the marvellous world of chemistry. Day by day opens up some fresh revelations, the line between organic and inorganic chemistry grows thinner and thinner, and the dreams of alchemy are as nothing compared with the possibilities which are yours, and it may be safely said that there is no profession which tempts to so many "fair fields and pastures new" as that in which you are engaged.

Of one thing let me warn you—there is danger in the very perfection of your training—danger in the knowledge you seek to gain, and which I hope you will rapidly acquire. Do not, I pray you, let the extent of your acquirements, or the breadth of your education, make you afraid of honest and humble toil.

This is the rock upon which many a fair ship has been hopelessly wrecked and gone to pieces. There is a dignity in labour consistent with the very highest acquirements and the greatest research. Never be ashamed of your daily work, and do not miscall it drudgery; make it your daily delight; seek in it opportunities for putting to a practical use the knowledge you have gathered; and remember there is no happiness so real and great as that which comes from a day's work well done, a day's duties nobly fulfilled, and an evening's rest well and truly earned.

I must now, ladies and gentlemen, ask your attention for a short time to one or two general questions affecting the interests of pharmacy, and then take some note of its progress during the past year. And, vexed question as it is, and threadbare as the discussion has been worn, it is impossible for me to pass over the poison regulation question without notice. I fear the lull which at present relieves our minds, is but the calm before the storm, and that when the time comes, we shall hear again the rising gale. I regret, gentlemen, most sincerely the decision arrived at by the Pharmaceutical Society at its last annual meeting, conceiving it to have been an error both in principle and policy; and with the absolute certainty, as it appears to my mind, that legislation will be enforced if we do not carry out the Pharmacy Act in its integrity, an Act granted "on the tacit but distinctive understanding that the Pharmaceutical Council should frame a code of regulations to be approved of by her Majesty's Privy Council," I earnestly trust that wiser counsels may prevail in the future.

It would be a curious comment upon the course advocated by the champions of "recommendations only" to ascertain by how many of them these recommendations had been carried out. I venture to predict it would be by a very small proportion. I am a firm advocate for regulations made and enforced by the Pharmaceutical Society under the sanction of the Privy Council.

We know what is needful and practicable, and can frame these regulations far better than they can be done for us by Parliament; but, unless this be done at once, I greatly fear it will be too late, and that all control will be taken out of our hands. But, whatever comes in the future, I hope nothing will arise to make any real or lasting breach in our own ranks; and, though we may differ widely, I trust all will consent to sink individual opinions in order in the best and speediest manner to secure the safety of those whose lives are intrusted to our care and skill.

I now approach the second portion of my subject,—a short *résumé* of the more prominent additions to pharmaceutical materials made during the past year; and I confess I wish this had fallen into abler hands. I shall be content, however, if, in my passing notice, I indicate some objects to which your attention may be profitably directed during the session.

And, although not entirely new, the prominence which has been given during the past few months to the therapeutic value of the "Nitrite of amyl" induces me to place it first on my list.

Nitrite of amyl, $C_{10}H_{11}O, NO_3$,* is an amber-coloured fluid, prepared by the action of nitrous or hyponitric acid on amylic alcohol. In the PHARMACEUTICAL JOURNAL for April last† were published some notes on its preparation by Mr. John M. Maisch, in which it is pointed out that the process for the preparation of this compound consists of two distinct operations; first, the production of the amyl-nitrous ether, and, secondly, its purification. In both operations the *very gradual* application and increase of heat is very essential.

Another process of manufacture consists in distilling amylo-sulphate of potash with nitrate of potash.

Dr. Richardson, to whom so much is due for his researches and discoveries in therapeutic science, and to whom, as is well known, we owe the introduction of hydrate of chloral, says of nitrite of amyl that it causes "paralysis of the chain of organic nerves, which supply the contractile power of the blood-vessels."

It thus induces muscular and arterial relaxation, increasing frequency of cardiac pulsation, accompanied by a very marked and sudden flushing of the face, warmth of head, face and neck, and perspiration, the perspiration often becoming general.

The safest method of administration appears to be by inhalation; five drops poured on a piece of lint, and held to the nostrils for ten or twenty seconds, until the face begins to redden. In from eight to twelve seconds the frequency of the pulse rapidly increases, rising sometimes from twenty beats in the quarter minute to forty.

Occasionally it produces some giddiness and headache; and it is evident that caution need be exercised in its employment in many cases.

In a most interesting paper by Mr. Talfourd Jones, published in the *Practitioner* last month, its physiological action and medicinal uses are most ably treated; and as we are expected to know not only the chemical properties of the remedies we dispense, but something also of their effects, and the purposes for which they are employed, I will read one extract, premising only that Dr. Jones has used the nitrite of amyl with some considerable success in spasmodic asthma, angina pectoris, epilepsy, laryngeal spasm and facial neuralgia, and that his investigations lead him to suppose that amyl is an antidote to the poison of chloral and ergot, and that it is likely to be a valuable agent in cases of overdosing by chloroform.*

A most singular and striking experiment follows, which clearly shows the effect of the nitrite upon the circulation.

Dr. Jones having cupped a patient suffering from dangerous illness, found the blood flow very slowly, and at length it ceased to run. At that moment it occurred to him that it would be interesting to watch just then the effects of the nitrite. Ten drops were immediately applied on some lint to the nostrils. Soon the radial pulse throbbed, then the face became flushed, and *at the same instant blood flowed freely into the cupping-glasses.*

It seems probable, gentlemen, that this remedy may become extensively employed; it is needful to be very cautious as to its absolute purity, as some of the specimens examined by Mr. Umney appear to have been very imperfectly prepared.

Some considerable attention has also been drawn to the wood and bark of a shrub known as "Condurango," grown in the province of Loja, Ecuader, and which is said to possess powerful medicinal virtues, and in the hands of Dr. Bliss and several other American physicians to have proved almost a specific for cancer.

Upon examination no crystalline alkaloid or active principle was separable by the usual methods, and by distillation no volatile oil or acid was obtained.

A small supply has been sent over to this country, and it has been tried at Middlesex and St. Bartholomew's Hospitals, and there does not appear to be any confirmation of its alleged virtues. Physiologically it appears to be practically inert, and its therapeutic effects in the treatment of cancer *nil.* The fear is lest some speculative and unscrupulous Yankees should vaunt it as a specific, and by a vile system of exaggerated puffing lead many unhappy victims of one of the worst diseases to which flesh is heir to seek impossible relief in a useless drug. If this should prove the case, it is well that we should know that condurango is pronounced most decidedly by English surgeons who have fairly tried it, and notably by Mr. Hulke, of Middlesex Hospital, to be worthless.

Passing to discoveries of apparently much greater value, you have probably many of you followed to some extent the interesting experiments of Dr. Richardson on the organic hydrides. Within the last month he has introduced to notice a new anæsthetic, which appears likely to prove very useful in short surgical operations.

* $C_5H_{11}NO_2$, according to the new notation.
† 3rd ser. vol. i. p. 865.

* See page 215, Case 1, *Practitioner* for October, 1871.

Dr. Richardson proposes to call this substance hydramyl-chlor., and I have a specimen of it on the table prepared for Dr. Richardson by Mr. Robbins. I cannot do better than give you a description of its preparation and effects in the doctor's own words:—

"Hydramyl-Chlor.

"In making bichloride of methylene, we place a mixture of alcohol and chloroform in contact with pure zinc. On the application of heat there is set up a brisk action, during which an equivalent of chlorine from the chloroform ($CHCl_3$) passes to the zinc, and, after a free escape of gases, bichloride of methylene (CH_2Cl_2) distils over. On my request, Mr. Robbins, while manufacturing some bichloride of methylene, added to the materials in the retort prepared for making the bichloride about eight times the volume of amyl hydride. The result was an immediate brisk action without the aid of heat. A copious stream of gases first passed over, and then, the fluid in the receiver having risen in temperature, there began to distil a compound fluid, very light specifically, and of a most agreeable odour. Collecting some of this fluid, I found it had a specific gravity of ·699, and that it commenced to boil at 92° F. It was much more manageable for inhalation than the simple hydride; was stable, and acted excellently as an anæsthetic. After carefully testing the vapour of this compound, I administered it fourteen times in cases of extraction of teeth, and with results almost identical with those that followed the administration of simple hydramyl.

"Finally, in repeating the process of distillation, the first portion that distilled over was set aside, and none was collected until the temperature had reached 90°, the temperature being sustained between that degree and the degree of temperature of the human body (98°). By this means there was obtained a fluid still very agreeable to breathe and extremely rapid in its action. This fluid has the specific gravity of rectified ether, viz. ·725. It boils in the warm hand, and may be considered as containing one part of bichloride of methylene in nine of amyl hydride. I propose to call this fluid 'hydramyl-chlor.' I administered the vapour of this fluid for the first time for a surgical operation on July 3. The patient was a young woman who wished to have a large firm molar tooth extracted. I placed two fluid drachms of the fluid in an inhaler specially constructed for it, and let the patient take the inhaler in her own hand and administer to herself. There was good anæsthesia in forty seconds, and ten seconds later Mr. Matthews took out the tooth without causing the least pain. The recovery was complete within the minute, and was neither attended with vomiting nor nausea. Since this case I have continued to administer the same form of vapour in short operations, and, so far, have every reason to be satisfied with the results. I have administered it to children as young as four years, and to adults of different ages up to seventy, and of both sexes. Mr. Matthews has also administered it a great many times for tooth-extraction at the Marylebone Dispensary with success equally good."

I can only just name the introduction of the organic bromides into pharmacy; they appear not unlikely in the future to occupy an important place, but my time and your weariness of my dry subjects must be my excuse for reserving a detailed notice for some future opportunity. Specimens of the bromides of quinine, morphia and strychnia are on the table. I will only name, as it may be a guide to some present, that the usual dose of the bromide of quinine is one grain, bromide of morphia one-eighth of a grain, and bromide of strychnia one-thirty-second of a grain.

Dr. Richardson states that they are soluble without the addition of any acid, but in practice we have not found this the case, and it is needful to add a small quantity of hydrobromic acid to each when preparing solutions or syrups from them.

Very recently attention has been drawn to the therapeutic value of theine—a substance, as you are aware, existing in tea and coffee, and which, up to the present time, has been looked upon rather as a chemical curiosity, than as a medicinal agent. It is a powerful tonic and stimulant, and a writer in the *Medical Times and Gazette* (Mr. Lewis Thompson) claims for it "the tonic virtues of disulphate of quinine united to the stimulating power of wine, but with this difference, that the stimulus from theine is not followed by any depression, as is the case with wine and alcohol."

It has been found useful in hemicrania, neuralgia and relapsing fever; and in cases of an over-dose of opium, it appeared to relieve the narcotic symptoms very speedily.

It is estimated that more than 140 tons of theine are wasted every year in the process of coffee-roasting, and Mr. Thompson states that by some modification of the the apparatus used for this purpose, theine may be produced at a cost of a few pence the ounce. By the present method, its cost is 15*s.* or 16*s.* an ounce. The dose which has been administered is from 1 to 5 grains. The specimen I have here is made by the old process; but I am informed that if the demand were sufficient, it could readily be manufactured in the manner indicated at a very small cost.

If it proves to possess the virtues attributed to it, we may soon expect a very formidable rival to cinchona products.

There appears to be a possibility that hydrate of chloral has seen its best days; for in some experiments conducted by Dr. Otto Liebreich, of Berlin, he has produced a new substance, to which he gives the name of "croton chloral," and which is produced by conducting chlorine gas into allylene. It has the peculiar effect of producing at first a high degree of anæsthesia in the head, whilst sensibility in other parts of the body remains intact. Some experiments have been tried with it in the university of Berlin and upon the insane, and it promises to produce all the good effects of hydrate of chloral, without any drawback to its judicious use. I am not aware that, up to the present time, any sample of it has been introduced into this country.

I must now apologize to you (and especially to the ladies present) for my dry address. I fear many of the latter have heartily wished that they had stayed at home; unless, indeed, any of them contemplate following the example of a Chicago virgin and entering into the ranks of pharmaceutical chemists. I think it possible the day may come when we shall have to welcome some of them at Bloomsbury Square; and you are well aware, gentlemen, that when the ladies once get either into our hearts, our pockets or our professions, there is no possibility, and I will add, very little desire, ever to get them out again.

BIRMINGHAM AND MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

The adjourned Monthly Meeting of the Council of this Association was held at its rooms, 24, Quadrant, Birmingham, on Friday, the 17th inst.; Mr. Geo. Dymond, the President, in the chair.

It was resolved at this meeting that the winter Conversazione be held at the Assembly Rooms of the Royal Hotel, Birmingham, and the rooms have since been engaged for Tuesday, the 6th of February. Free cards of invitation will be issued to *all members*, each admitting a lady and gentleman, and to associates, admitting a gentleman; and a certain number of invitations will also be issued to many of the medical and scientific gentlemen of the neighbourhood. (Intending members are requested to enrol their names as early as possible.)

A portion of the rooms will be devoted to an exhibition of objects of pharmaceutical, medical and scientific interest. Intending exhibitors who desire to avail themselves of this opportunity of bringing any specimens, instruments, preparations or other articles under the notice of those who will be present, are requested to communicate early with the Secretaries, Messrs. J. Lucas and W. R. Jones, 24, Quadrant Chambers, Birmingham.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, November 16, 1871; Dr. ODLING, Vice-President, in the chair.

The ordinary business of the Society having been transacted, the SECRETARY proceeded to read a paper "On Burnt Iron and Steel," by W. H. Johnson, B.Sc., in which the author commented on a former paper on the same subject by Mr. Williams, stating it to be his opinion that the steel became burnt through the agency of the carbonic acid present, and not through there being any free oxygen in the hottest part of the furnace. Mr. S. Bell had found that the oxidizing effect of the carbonic acid and the reducing action of the carbonic oxide went on simultaneously, varying, however, with the temperature; so that if the carbonic acid were present in sufficient quantity, its oxidizing effect would exceed the reducing effect of the carbonic oxide, and the iron or steel would become burnt.

An interesting discussion ensued, during which Mr. RILEY mentioned several curious facts which he had observed during his experience.

Mr. F. W. HART then gave a description of an improved form of siphon, and, finally, the meeting adjourned until December 7, when a paper will be read by Dr. Gladstone "On Essential Oils."

SOCIETY OF ARTS.

DYES AND DYE-STUFFS OTHER THAN ANILINE.*

BY DR. CRACE-CALVERT, F.R.S.

LECTURE II.

Red Colouring Substances (continued).—Munjeet; Campechy Peach, Sapan, Cane and Bar Woods; Alkanet Root; Safflower; Cochineal, Lac Dye; Murexide.

Munjeet.—It is to the researches of Dr. John Stenhouse, one of the most eminent and learned of English chemists, that we are indebted for our knowledge of the true composition of many of the dye-stuffs, and it is to him that we are indebted for the whole of the information we possess in the colouring matters of munjeet, or *Rubia munjista.*

This peculiar variety of the genus *Rubia* is cultivated exclusively in Asia, and especially in India, where it has been used as a dye-stuff for a long period of time, either alone or mixed with other dyes, to produce a variety of red shades. It is imported into this country from time to time, but has never been extensively used, as the colours produced from it are neither so fast nor so bright as those obtained with *Rubia tinctorum.*

Whilst the colouring principles of madder are purpurine and alizarine, those of munjeet are purpurine and a yellow colouring matter, named by Dr. Stenhouse munjistine. He has assigned to this latter body the formula $C_{16}H_8O_6$. When crystallized from an alcoholic solution, it forms large, beautiful, golden-coloured flakes, which, sublimed, give prismatic crystals of an orange-red colour. It is only slightly soluble in cold water, but freely soluble in hot water. Its best solvent is bisulphuret of carbon, which was employed with success by Dr. Stenhouse in separating the purpurine and munjistine from the other substances existing in munjeet. He states that the munjeet root contains as much colouring matter as the *Rubia tinctorum,* and, according to Mr. Higgins, of Manchester, it yields from 52 to 55 per cent. of a garancine; but as it has only half the dyeing power of ordinary garancine, it cannot be employed with advantage for this purpose. The inferiority of munjeet arises from its containing only the comparatively feeble colouring matters, purpurine and munjistine. Munjeet is not much used by calico printers, as the munjistine gives a brownish purple with salts of iron, which prevents it being employed with that mordant. It is used for special shades of Turkey red, the munjistine giving, with salts of alumina, an orange-yellow colour, which is in some instances employed by the dyers.

I have now the pleasure of calling your attention to an important class of dyeing substances, "the dye-woods."

Campechy or Logwood.—This wood, obtained from a large tree of the leguminous family, called by the botanist *Hematoxylum campechianum,* grows abundantly in the West Indies, Mexico and other states of South America. The best quality is imported from the Bay of Campechy, in the Gulf of Mexico. Large quantities are also obtained from Jamaica and St. Domingo. The qualities obtained from Honduras, Martinique and Guadaloupe are inferior.

Campechy was introduced into Europe by the Spaniards, but it was not till the reign of Elizabeth that it came into use in England, and then only for a short period, after which its employment was forbidden under the severest penalties for upwards of a century.

The discovery of its colouring principle, hematine, was made in 1810, by my learned and venerable master, M. Chevreul (who, although now 85 years old, is still actively engaged in scientific pursuits). Shortly afterwards it was studied by Ermann, who gave it the name of hematoxyline. It was obtained by these eminent chemists as yellowish-white prismatic crystals, which become discoloured by contact with the oxygen of the air and the small amount of ammonia which the atmosphere contains. It is only slightly soluble in cold water, but much more so in hot. It is very soluble in alcohol, ether and bisulphuret of carbon. It combines with three equivalents of water, forming a crystalline hydrate, which at 212° F. retains one equivalent.

Hematine in the presence of oxygen, especially under the influence of alkalies, assumes a beautiful purple colour. This colouring-matter can be obtained under the form of purple-black crystals, having a metallic lustre, and has received the name of hematëine. Hematine has the formula $C_{16}H_{14}O_6$, which, on conversion into hematëine, becomes $C_{16}H_{12}O_6, H_2O$. The hydrate is $C_{16}H_{14}O_6, 3H_2O$, which, at 212° F., becomes $C_{16}H_{14}O_6, H_2O$.

The oxidation, and consequent coloration, of hematine under the influence of oxygen and alkalies, is so rapid that it may be used as a most delicate test of the presence of carbonate of lime in natural waters; and it is a fact well known to practical dyers that waters containing a large quantity of carbonate of lime are well adapted for the production of good logwood blacks. Hematine gives little or no coloration with salts of protoxide of iron, but hematëine gives a dark purplish blue; the latter also gives dark blue precipitates, with salts of lead and tin. Hematëine is easily reduced to hematine by hydrogen and sulphuretted hydrogen.

In my opinion the colouring matter in *Hematoxylum campechianum* exists in the state of a glucoside, for when the trees are felled the wood is colourless; but by the time the logs arrive here the outside is of a dark red colour, whilst the inside has only become of a pale yellow colour.

As hematëine is the principle which the dyer requires,

* Cantor Lecture, delivered Tuesday, Feb. 14. Reprinted from the *Journal of the Society of Arts.*

the logs are ground into a coarse powder, which is moistened and laid in beds 15 or 20 feet long by 10 or 12 broad, and about 3 feet thick. A slow fermentation ensues, by which the glucoside is decomposed, and the hematine liberated. It is converted into hematëine by stirring the mass, thus exposing it to the oxygen of the air, the action being quickened by the ammonia of the atmosphere, as well as by that given off by the decomposition of the azotized principles existing in the wood.

This prepared wood is used by the dyer to produce logwood blacks, as I shall describe further on, and also by wood-extract manufacturers, who prepare an extract which is much used in calico printing. To prepare this extract it is necessary that the wood should not be too highly oxidized, and that the solution obtained from it by successive and repeated lixivation should be slowly concentrated at a comparatively low temperature, that is to say, not exceeding 150° F.; for if a high temperature be employed the hematëine is still further oxidized, and a dark purple resinous principle produced, which spoils the brilliancy of the colour.

This extract is chiefly used in print-works, to produce purples in steam styles.* A strong logwood solution is thickened with starch, and printed on a prepared cloth; that is, a cloth that has been passed through a solution of stannate of soda, then through weak vitriol, by which means the binoxide of tin has been fixed as a mordant in the fibre of the cloth; the fabric, after washing and drying, is ready for the printer. After being printed, the cloth is either rolled on a perforated cylinder or hung in an iron chamber, and submitted to the action of steam, when the hematëine combines with the oxide of tin, producing a beautiful purple.

If blacks are to be produced, an iron mordant is fixed on the fabric, which is then passed through a logwood solution. It is afterwards washed, and the black fully developed by passing it through a hot dilute solution of bichromate of potash.

Logwood and its extract are much used in Yorkshire for producing cheap blacks on mixed fabrics, which are goods in which the warp is cotton and the weft woollen. The black is produced by dyeing the fabric in a bath composed of logwood, sulphate of soda and bichromate of potash.

It is often very useful to distinguish logwood blacks from sumach and other fast blacks, and logwood purples from aniline purples. This is easily effected by submitting the piece to the action of weak acids; the logwood colours assume a bright red tint, while the others remain unchanged.

Brazil Wood.—We shall now pass on to a series of woods which are all obtained from the genus *Cesalpinia*, belonging to the Natural Order *Leguminosæ*.

Although these woods have long been employed as dyes by the natives of the countries where they grow, it is only since the introduction of Brazil wood by the Spaniards that their value as dye-stuffs has been known in Europe. The best qualities are all imported from Brazil. The particular wood known as Brazil wood, derived from *Cesalpinia braziliensis*, has become scarce in the market, from its having been all cut in the districts within easy distance of shipping ports.

The woods most in favour at the present day comes from Pernambuco, and is the *Cesalpinia Christa*. This tree is also found in Jamaica. That obtained from Sierra Nevada is not of such good quality.

Another variety, bearing the name of peach-wood, is chiefly derived from Nicaragua. A third, known as Sapan-wood, comes principally from Siam, the East Indies and other eastern countries. A rather inferior quality, known as Lima-wood, is imported from Peru.

All these woods appear to contain the same glucoside, and, like the previous ones, are decomposed by peculiar ferments into a saccharine matter and a colour-giving principle. This is proved by the following experiments. If the decoction obtained by treating the wood from the interior of the sticks be boiled with a solution of double tartrate of potash and copper (the best known test for grape sugar), no precipitate is obtained; while, if the glucoside be first decomposed by boiling with a dilute solution of hydrochloric or sulphuric acid, and afterwards treated with the copper salt, an abundant precipitate of suboxide is thrown down. The decoction, which has only a faint yellow colour, gives a most abundant and brilliant precipitate with subacetate of lead. The colour-giving principle was discovered by M. Chevreul, who gave it the name of *braziline*. By oxidation it is converted into *brazilëine*. It also combines with water, to form a hydrate containing two equivalents of water. Professor Bolley gives the formula of braziline as $C_{22}H_{20}O_7$, and that of the hydrate $C_{22}H_{20}O_7, 2\,H_2O$. He has also made the curious observation that a comparison of the formulæ of hematine and braziline shows a difference equal to carbolic acid, as may be seen by the following table:—

Braziline	$C_{22}H_{20}O_7$	
Hematine	$C_{16}H_{14}O_6$	
Difference	$C_6\,H_6\,O$	Carbolic acid.

What is still more remarkable is, that by the action of nitric acid upon hematine, he obtained oxalic acid, whilst under similar circumstances braziline yields oxalic acid and picric or trinitrophenic acid, which is the product obtained when carbolic acid is acted upon by nitric acid.

A decoction of any of these woods becomes yellow or orange (according to the quantity of braziline or brazilëine it contains) on the addition of an acid, and by the addition of an alkali, a beautiful crimson red, the shade of which varies according to the proportion of the two principles. It also becomes red with bichromate of potash, and gives a red precipitate with oxymuriate of tin.

These characters are sufficient to distinguish between a solution of these woods and one of logwood.

To prepare a good commercial extract from these woods, they must be finely ground, as they yield their colour to water with difficulty; like logwood, they must be allowed to ferment and oxidize in the air, but not to the same extent. The concentration of the decoctions differs from that of logwood in the fact that they can bear a higher temperature. The more quickly they are evaporated, the brighter are the colours which the extract gives. Dr. Dingler has proposed a process which is stated to give very good results. It consists in adding 4lbs. of gelatine, dissolved in water, to every cubic yard of ground wood, and allowing the whole to ferment for several days. The wood so treated yields a stronger and richer extract than that obtained by the ordinary process; no doubt the gelatine helps the decomposition of the glucoside, and the ammonia produced facilitates the oxidation of the braziline. By the addition of a small quantity of chlorate of potash to the hot extract, Mr. Peak greatly increased its brilliancy, and rendered it more valuable to the printer on account of the brighter colour produced on the fabric.

These extracts are principally used to obtain pinks and reds in steam styles. To effect this, acetate of alumina, chloride of tin, oxalic acid, or acetate of copper is added to the extract, and printed on the prepared cloth already described, which is then submitted to the action of steam.

These woods are also used in conjunction with a little quercitron, or bark, in the production of cheap garancine styles. These inferior garancine prints are easily

* Calico printers employ the word style or govels when speaking of a class of goods which are denoted by a word characterizing the colouring matter used, or the method employed in producing them. Madder goods and garancine styles may be given as examples of the first, and steam styles of the second.

distinguished from the good ones by means of a hot soap-bath, which only slightly affects the good, while the inferior are almost entirely destroyed. The woods also are sometimes used for the adulteration of garancine.

I may state, before leaving this subject, that the decoction of these woods yield very beautiful pink lakes, which are principally used by paper-stainers.

Common red ink is also prepared by adding a little alum and acid to an aqueous solution of these woods.

(*To be continued.*)

Parliamentary and Law Proceedings.

Death from Opium-eating in a Workhouse.

On Thursday, November 16th, an inquest was held at the Salford Workhouse, concerning the death of Elizabeth Owen, aged sixty-eight, an inmate.

Mr. John Tatham, medical officer to the workhouse, said, on the evening of the 14th inst. he was sent for by one of the day nurses to visit the deceased. She was in bed, and almost insensible. He endeavoured to rouse her, but could only do so partially. From her appearance he suspected she had taken an overdose of opium. He ordered her to be got out of bed, and to walk about the room for some ten minutes to keep her awake, and while an emetic was being prepared. An emetic was administered to her, and he afterwards used the stomach-pump, but the emetic did not act. The deceased had gradually become more insensible, and died about nine o'clock. He made an examination of the body, and found the vessels of the brain enormously loaded with blood, quite sufficient to account for death. He was clearly of opinion that congestion was the result of her having taken a narcotic poison. He did not think it necessary to examine the stomach, as in all probability the traces of opium would have been removed. Deceased could only have got opium in sufficient quantity to produce the effects he saw from outside the house. It was contrary to the rules of the house to import anything whatever into it for the use of the inmates. He perfectly well remembered having taken more than ordinary notice of the deceased when he went his rounds on the day of her death. The medicine she was taking contained but a small quantity of opium, and she might have taken all that was in the bottle without any ill effects following. No other poison would, he thought, produce all the symptoms he found, coupled with the congestion of the brain.

Evidence was given by a paid nurse that in August last she received a piece of opium, about three times the size of a pea, from one of the male inmates with a request to give it to deceased. Witness handed it to the superintendent. Upon deceased being spoken to about it she promised not to offend again. Another nurse said that she had received a piece of opium from deceased which she gave to the superintendent. It was also stated that deceased was in the habit of taking laudanum before she went into the workhouse.

The jury returned a verdict in accordance with this evidence, and the coroner wrote a letter to the Salford Board of Guardians, calling attention to the great probability, almost amounting to certainty, that the deceased was supplied with opium by other inmates, who were from time to time allowed to leave the house temporarily.—*Manchester Courier.*

Adulteration of Bread by Alum.

At the Manchester police court, on November 17th, three bakers appeared in answer to summonses, upon a charge of mixing alum with the bread made by them. The prosecution was instituted by the Manchester and Salford and District Master Bakers' Association, and one of the defendants was a member of the Association. Evidence was given as to the purchase of certain loaves, which were ticketed and sent to Mr. Jones, Owens College, for analysis.

Mr. Jones said he had examined the loaves with the following result:—One loaf contained 6·41 grains of alum per lb.; a second 5·75 grains per lb., and the other 5·55 grains per lb. The quantity of alum was sufficient to produce some effect upon a person eating the bread.

The cases were adjourned for a month.

Death from an Overdose of Chloral Hydrate.

An inquest has been held at Leicester to inquire into the circumstances attending the death of Mrs. A. Turner. A servant in the employ of the deceased deposed that being unable to obtain an answer from her mistress the room was entered, when Mrs. Turner was found dead in her bed, and a bottle labelled "Syrup of Chloral Hydrate," lying near her.

Samuel Goodhall Cox said, I am a chemist and druggist, residing in Gallowtree-gate, Leicester. I knew the deceased lady, from her having been an occasional customer. On Monday evening last, between five and six o'clock, she came to my shop alone, and asked me for the mixture of chloral hydrate, which she had had before. On my giving the mixture to her in a four-ounce bottle, the deceased asked me if I would make it of double strength. She said she had taken two teaspoonfuls of the mixture she had had before, and she wanted to have the dose in one teaspoonful. I prepared the chloral hydrate as the deceased wished, and had no hesitation in doing so. I particularly impressed upon her that I had made it double the strength of the other she had had, and she seemed perfectly to understand its properties and action. She also purchased a quantity of sal volatile and eau de Cologne. She then went, away, and nothing more took place. I had only supplied the deceased with one bottle of chloral hydrate previous to Monday last. On that day she told me she could not get any sleep without it, as she suffered from neuralgia. The deceased had asked for quinine for neuralgia, and I served her with that drug also in a bottle. That drug she also had in a concentrated state for convenience in taking it. The bottle which contained the chloral hydrate is a four-ounce bottle, is properly labelled, and would contain about thirty-two doses. The bottle is now nearly half empty, and I should think that about twelve doses are gone from it.—(By the jury): I have seen a quantity of chloral hydrate equal to four teaspoonsful of the strength contained in the bottle produced, taken without ill effect. If sal volatile were to be taken at the same time as chloral hydrate, it would increase the action of the latter. The contents of the chloral hydrate bottle are poisonous if taken in an unreasonable quantity, but it is not a legal poison, and druggists are not obliged to label it "poison." There are poisons which are obliged to be registered, and others which are only labelled. Chloral hydrate is not a poison that has to be labelled as such.—(By the coroner): The bottle now shown to me is the one in which I supplied the sal volatile to the deceased on Monday. It is now empty.

Mr. C. Bowmar, surgeon, said that he had been sent for to Mr. Turner's. He found the deceased had been dead for some hours. There had been no sickness or purging, indicative of any irritant poison having been taken. The four-ounce bottle produced, which contained chloral hydrate, was lying by her side, and nearly half empty. He saw that the bottle was properly labelled, and where it was from. There was a sufficient quantity gone from the bottle to cause death. His opinion was that death arose from taking an overdose of chloral hydrate. There was no appearance of struggling. He had been deceased's medical attendant for some time. She had frequently said, "You must give me something to sleep me." He had heard her complain of pains in the face and head, but not often. He had prescribed chloral for her several times. He was not aware that she knew anything about the properties of chloral hydrate, but she was a great reader, and probably she did. He did not think it probable that deceased had intended to commit suicide, but that she had drunk the chloral hydrate out of the bottle without measuring it.

A verdict to this effect was returned by the jury.

Accidental Poisoning.

On Saturday evening, November 18th, Mr. Richards held an inquest at Mile End Old Town, upon the body of James Robert Ludlow, aged three weeks, the son of Mary Ludlow, of Mile End. The deceased was troubled by a cough, and the mother sought the advice of her landlady, who gave her a bottle of cough mixture which had been prepared for the son of the latter, aged five. Half a teaspoonful was administered to the deceased, but the mixture was too powerful, and killed the child.

Dr. Corner proved that death was the result of exhaustion, consequent upon an overdose of paregoric and syrup of squills.

In summing up, the coroner drew pointed attention to the fact that many people ran away with the idea that because a child two or three years old could take a spoonful of a certain mixture without danger, a younger child could safely have a smaller quantity, but the case in question showed how utterly fallacious such an idea was. Verdict, "Death by Misadventure."

Obituary.

MR. JOHN BALMER.

We record with unfeigned regret the decease of this most amiable of Pharmacists who expired at St. Leonards in his seventy-second year.

He had long been in a precarious state of health and therefore the unwelcome event created no surprise amongst his friends. It is often said, *de mortuis nil nisi bonum*, but it is no mere compliment to state that few have surpassed Mr. Balmer in winning gentlenss of manner: not many have so studied the happiness of those around them. He possessed moreover that excellent gift too little cultivated in our day, a cheerful disposition.

He was apprenticed in Chester, we believe with Mr. Bowers. There happened to be in that ancient city another apprentice, the late William Ince, whose son writes these lines. Time passed and both eventually found themselves at Godfrey's establishment in Southampton Street in the Strand. This will explain why their intimate friendship should have been commenced, interrupted as it was but for a short period by the grave.

After a certain interval, Mr. Balmer established himself in St. John's Street Road, close by the Angel, with which locality his name has been so long connected. His old friend from Chester lived then close by, being separated only by a celebrated theatre which probably neither ever entered. Pleasant memories crowd upon the mind as we recall the frequent social gatherings in "Merry Islington," when youth listened while wise men talked, and when the two families were one.

In business Mr. Balmer was successful more particularly as he enjoyed not only the confidence but the private esteem of several eminent medical men amongst whom may be mentioned Dr. Dobell, Dr. Sansom and the late Dr. Golding Bird.

He was fond of experimental Pharmacy, and the occupation of what might be perhaps called his leisure was devoted to the investigation of new and supposed better methods of exhibiting Pharmaceutical preparations.

He was one of the first, if not the original maker of the Pancreatic Emulsion the therapeutical value of which is inseparably connected with the name of Dr. Dobell already mentioned. He was interested in the introduction of the Sulpho-Carbolates, and was a careful manipulator of Essences and Liquors. Indeed he was constantly at work on this class of remedial agents. One of the latest and most useful of his improved preparations was a Belladonna Plaster made by the use of resinous extract of Belladonna *root*, in preference to that made with the spirituous extract of the leaf. This plaster was recommended as requiring no adhesive margin and being cleanly in its use.

He made formerly an admirable Extract: Ignatiæ Amaræ, and in short, this department of retail laboratory work was his delight.

Of his dress and personal appearance it would seem rude to speak, but both were characteristic. He considered untidiness a sin.

His unaffected piety can barely be alluded to though it was the golden thread which bound all the actions of his life together. Now he has entered into rest, in sure and certain hope of the Resurrection to eternal life.—J. I.

MR. GEORGE WHIPPLE.

We regret having to record the death, on October 31st, of Mr. Whipple, one of the early and frequent contributors to the proceedings of the Pharmaceutical Society. For many years Mr. Whipple was engaged in the manufacturing department of the well-known house of Barron, Harvey and Co., of Giltspur Street, in which establishment, having the sole management of the laboratory, he had acquired a large amount of practical knowledge relating to the preparation of medicines. Those who were accustomed to attend the evening meetings of our Society during the first twenty years of its existence, will hardly require to be reminded of the numerous occasions on which valuable information was communicated by a gentleman who was rarely absent from those meetings, and was always ready in his peculiar and impulsive way to add to the common stock the results of his long and varied experiences. Nor was it in this way only that Mr. Whipple contributed to the advancement of the profession to which he belonged, for to those engaged in scientific inquiries his note-book was always open, as the works of Pereira and others can testify.

Advancing years and declining health caused Mr. Whipple to retire from his appointment in Giltspur Street in 1858, and since that time he has rarely appeared among the pharmaceutical friends with whom he had previously associated, and by whom he will long be remembered as an active, zealous and liberal-minded promoter of the scientific objects of the Pharmaceutical Society.

Among the papers that Mr. Whipple read at the Evening Meetings of the Society and contributed to this Journal may be mentioned those on "Essential Oil of Bitter Almond obtained from Almond-Cake," "Extract of Colocynth," "Purification of Essential Oil of Bitter Almonds," "Sulphate of Soda contained in Quassia Wood," "Remarks on the Preparations of the Pharmacopœia," etc.

MEETINGS FOR THE ENSUING WEEK.

Monday Nov. 27.	*Medical Society*, at 9 P.M. *London Institution*, at 4 P.M.—"Smell, Taste and Touch." By Professor Huxley. (Educational Course.)
Wednesday Nov. 29.	*Society of Arts*, at 8 P.M.—"Tramways and their Structures, Vehicles, Haulages and Uses." By Mr. W. Bridges Adams. *Geological Society*, at 8 P.M.
Thursday Nov. 30.	*London Institution*, at 7.30 P.M.—"Science and Commerce, illustrated by the Raw Materials of our Manufactures." By Mr. P. L. Simmonds. *Royal Society*, at 4 P.M.

Correspondence.

The Improved Tincture Press.

Sir,—My attention has been called to several letters which have appeared in your valuable Journal relative to the tincture press.

Mr. Staples appears to have been the first in the field recommending his double screw press in preference to the ordinary single screw, because such screws are subjected to a longitudinal tensile strain, instead of a perpendicular thrust or crushing strain, this latter having a tendency to bend the screw, or force it out of the perpendicular.

This is quite correct, providing the screw is too small to bear the strain, but it is not likely the press maker would fall into this error, for presuming that the bending or distorting of the screw was a general complaint, some one would have surely long since made a press with two screws instead of one.

Mr. Staples' press is of so primitive a character, that it appears to me to be such an one as would probably have been made 100 years since, before engineering skill had constructed machinery for cutting screws.

It must not, however, be despised for its primitive character, for there is one thing in its favour, it is simple, and can be made at a small cost. But as the ordinary screw press can be bought of any druggists' sundriesman for ten shillings and upwards, I do not think that the double screw press could be made for much less.

But then Mr. Staples says his press is so much more powerful than the ordinary variety, upon which Mr. Umney commented, basing his calculation on the pitch and diameter of the screws. This again is quite true, for one can make the screws of any power, provided the whole fabric is sufficiently strong to resist the pressure; and here it is that Mr. Staples is so greatly in error.

Mr. Staples estimates the power of his press at 20 tons, with screws of $\frac{1}{8}$ inch pitch, and $\frac{1}{2}$ inch diameter, or 10 tons resistance to each screw; and in his letter of the 21st Oct., he thanks Mr. Umney for inducing him to investigate his press more closely, and is so astounded at its enormous power that he says he feels some diffidence in stating that his estimation is now 30 tons.

I am really astounded myself, and should like to know where the iron was made to withstand such a strain.

Mr. Staples has quite ignored the all-important point in his calculations, viz. *the cohesive power of the iron*, of which the screws are made.

The argument now wholly turns upon this, and resolves itself into the following question:—What is the ultimate resistance of the iron composing the screws?

In answering this question, I will give Mr. Staples the benefit of the whole diameter, viz. $\frac{1}{2}$ in.

The ultimate strength of a 1-inch round bar of English iron is 43,881 lbs., which, divided by 4, is 10,970 lbs. as the ultimate strength of a bar of $\frac{1}{2}$-inch diameter; but as the press has two screws, 10970×2 must be the ultimate strength of both screws, or 21,940 lbs. (9·3 tons) as the breaking-strain.

Now with engineers it is customary, in order to ensure safety, to take the working strain at *one-third the cohesive power of the iron;* this would reduce the power of the press of Mr. Staples' design to 3 tons 3 cwt. ($9·3 \div 3·1$ tons). How then is it possible for Mr. Staples to give 30, or even 20 tons, as the power obtained by his press?

Mr. Staples, however, not content with 20 or 30 tons, even soars to 50 tons, which astounding and magnificent power is (he says) to be obtained and resisted by two highly-finished steel screws, with threads of $\frac{1}{12}$ of an inch.

Now I will give him *shear* steel, which has about double the strength of iron, then $9·3 \times 2$ or 18·6 tons would be the ultimate strength or breaking-strain.

Surely, therefore, it is perfectly absurd to talk about 20, 30 or 50 tons?

Then again, Mr. Staples has said nothing about the dimensions of the wooden base, or his cross bar.

I see in a very sensible letter in your last issue by Mr. B. Groves (who, although not a practical mechanic, has his head screwed on in the right direction), that he is the first to make allusion to them.

I should like here to caution Mr. Groves when trying his experiment with his wind-bag, that the highly compressed air does not suddenly burst its casement, and send the pieces flying at him. It would be far better if he wishes to try his experiment, to get a solid lump of india-rubber interposed between the marc and the screw; he may rely upon it, however, that the spring, if tried, will be of no manner of use, nothing can be gained by it, for it only forms part and parcel of the cross bar.

Mr. Groves observes that the intensity of the pressure exerted is always proportionate to the area over which it is spread, so that the pressure per square inch on the material can be made more or less by decreasing or increasing the surface of action. This very sensible remark, which he says is often lost sight of, has surely escaped Mr. Staples, for he does not even mention the diameter of his cylinder.

I would certainly advise Mr. Staples to give up the contest, for what good has it done? save that it has brought about a contention of who is right in estimating the power of a screw press, and whether the power applied should be taken at 50 or 100 lbs.

Now the fact is, one can estimate the power at anything *within the limits of the strength of the materials* of which the press is composed.

Anything beyond this is but a *reductio ad absurdum*.

"An Old Engineer."

Sir,—Mr. Groves essayed to determine, experimentally, the power which a man of average strength can exert in turning the lever of an ordinary screw-press, by applying, as the resistance to be overcome, a force acting vertically at the extremity of the lever,—the influence of the iron pulley employed being merely to change the direction of the force, and, by friction, to diminish it slightly.

If the rope had been attached to the head of the screw, Mr. Groves would have succeeded in solving the problem of the actual pressure exerted by the tincture press, since the resistance of the marc is a force acting vertically upwards; but that as a measure of the manual strength exerted in pressing, his result involves a huge fallacy.

Of course, a resistance applied to one extremity of the lever, could only be counterbalanced by a force equal to it, applied to the other, since the fulcrum is central; but when a weight is raised from the ground by the downward united progress of the lever and screw, the mechanical advantage of the latter contributes to the result.

Thus, assuming that the circumference of the screw in Mr. Groves' press was six inches, and the distance between the threads half an inch, and disregarding friction, the actual manual strength required to lift from the ground a weight of 216 lb., would be $216 \div 12 = 18$ lb.

This may appear ridiculously below the truth, but it should be borne in mind that the press was situated in a recess, and the operators may have been thereby cramped for room, also that the friction may have been considerable.

It has occurred to me that the compressor recently described in the *Times* as being employed to ascertain the expansive force of the charges of powder used for our heavy guns, might be adapted to show the actual pressure which the press-cylinder and its contents are called upon to resist.

Dover, Nov. 21st, 1871. J. Frederick Brown.

[*** Our correspondent appears to have misunderstood the arrangement adopted by Mr. Groves, inasmuch as he supposes the resistance overcome in the experiment to have been a force acting vertically at the extremity of the lever. We assume, however, that in Mr. Groves' experiment the resistance acted horizontally.—Ed. Pharm. Journ.]

Difficulties in Dispensing.

Sir,—The recommendation to which T. B. takes exception was challenged at the meeting before which my paper was read, although not mentioned in the report of the discussion that followed, but I really cannot see that the practice is so objectionable as he would make it appear.

I acknowledge that it is our duty as dispensers of medicine to carry out the intentions of the physician, and that we ought as far as possible to avoid "making material alteration in a prescription without the sanction or knowledge of the physician," but I contend that it is also our duty to present the medicine (if we can) in such a shape that the patient can take it without inconvenience.

Everybody knows that we often get prescriptions for pills which, if made strictly as prescribed, could not be formed into pills at all. This is one I had to make up to-day,—

Podoph. gr. xij
Scammon. gr. xij
Ext. Rhei gr. xlviij
Ol. Cinnam. gtt. xxiv
Ft. pil. xxiv.

which, if dispensed as written, would be about the consistence of treacle; and, in the cases objected to, I only stated what I considered the best method of doing that which practically every one does in private.

In most cases it would not be possible to communicate with the prescriber, and very few would thank us for doing so. I fancy a physician would be very much astonished to see me take one of his prescriptions, tell him the pills would be much too soft, and ask what I should do in the matter. I think he would tell me that I ought to know how to manage all that without bothering him, and I fear he would form a very low estimate of my qualifications as a dispensing chemist, and would tell his patients not to bring their prescriptions to me.

If T. B. will prove his assertion that, "in each of the cases named, no such difficulty exists as to render the change necessary," and will show us a "more excellent way," I for one shall be greatly obliged, as I do not consider myself too old to be taught. I should be glad, also, to know what he would have done with the following:—

R. Hyd. Chlor.,
Ext. Colch. Acet. ana gr. j
Ext. Rhei gr. ij
Ext. Coloc. Co. gr. v
Finge in pilulam. Sumat duas h. s.,

not being able to consult the prescriber.

Cheetham Hill, Nov. 20th, 1871. W. WILKINSON.

Sir,—It is with great pleasure that I read in the Journal of the 18th, the remarks of your correspondent T. B., upon Mr. Wilkinson's paper. I venture to take the liberty of supplementing them.

When I read Mr. Wilkinson's paper in the Journal of the 11th, I was astonished that so bad a practice as that urged by Mr. W., viz. the trifling seriously with a physician's prescription in order to render it easier of preparation, should have excited no surprise (if any expressions of indignation did take place, I presume place would have been found for them in the Journal). I can only explain it by the presumption that the Manchester chemists have but lax notions of the duties of their calling. It seems to me that the substitution of p. gent. for ext. gent., and of p. hyoscy. for ext. hyoscy., and the omission of half the essential oil ordered in a quantity of pills, are far too great liberties to be taken by any chemist. I also think the whole tendency of that part of the paper alluded to, would tend to lead apprentices and some assistants to think they are doing but right, even if they go a little further, and, for the sake of convenience, profit, or saving of time or trouble, omit or substitute by others, the ingredients of any prescription confided to them.

In conclusion, I would advise all dispensers rather to send out occasionally a somewhat badly manipulated medicine, than depart seriously from the use of the quantities ordered in a prescription, without the consent of the physician.

Leicester, Nov. 20th, 1871. WALTER B. CLARK.

PHARMACEUTICAL EDUCATION.

Sir,—At the present time when so much surprise is expressed at the number of those plucked for both the Minor and the Preliminary, I think less would be felt if the circumstances in which many apprentices are placed were more fully known.

A man calling himself a chemist and druggist, often more of a quack-doctor, takes a youth as an apprentice, with little or no Latin and barely sufficient English even for the Preliminary. For four years, perhaps five, he struggles on, working his twelve hours per day, and learning what? chiefly how to serve a pennyworth of hair-oil or a box of capsules. As to prescriptions, he scarcely ever sees one, and when he does, what sort of dispensing is he to learn from using tinctures, half-and-half, with perhaps the additional peculiarity of having their expensive adjuncts left out?

And when he comes out of his time he finds that he has been deceived,—robbed of four of the most valuable years of his life; has to begin the world anew, nay, more, to eradicate those notions derived during his apprenticeship. It is a monstrous crime for a man to sign to teach a boy the "art and mystery of a chemist and druggist," and, at the same time, know that he is incapable of doing so. But there are many such cases spread over the country, and are not at least some of the failures traceable to them? It has been stated, and upon good authority, that the better class of pharmacists decline taking apprentices. If so, are we to understand that if not on the increase, this unfortunate class is still kept up?

November 20th, 1871. METEOR.

Sir,—On the subject of professional education, allow me to make a few remarks.

Under the new *régime*, before a young man can commence business as a chemist, he is compelled to undergo a somewhat difficult examination, therefore study during the term of his apprenticeship is absolutely necessary, and a certain time should be allowed him for that purpose. But in most cases apprentices are obliged to work from 7.30 A.M. until 9 or 10 P.M., during which time no opportunity is afforded them (except at those periods, say two or three times a week, when grace is given them for necessary relaxation and exercise). Under such circumstances it frequently occurs that candidates who go up for examination are plucked, not from a want of zeal and attention on their part, but mainly because the necessary preparation and proper time for study have been overlooked by the employers during their term of apprenticeship. Y. Z.

T. W.—Your communications are received and shall have attention.

"A Correspondent."—Britten's 'Dispenser's Vade Mecum' is sold by Messrs. Maw, Son and Thompson, price 3*s.* 6*d.*

S. C.—We think that you might obtain the work through the publishers of this Journal.

John Jinks.—Apply to the Registrar for a paper containing some "Hints to Apprentices and Students," in which you will find the information you require.

H. E. R.—Mohr and Redwood's 'Practical Pharmacy' is the only English work of the kind with which we are acquainted, but we believe it is out of print.

J. P. T.—The subjects may be taken in any order. If we may judge from the letter received, we would recommend our correspondent to pay particular attention to the study of English before he again presents himself for examination.

T. David.—Probably *Echium vulgare*, but the specimen is much injured.

"Taraxacum."—We think a machine similar in construction to the bark-mill used by tanners for reducing into shreds oak-bark would answer very well. Such a machine is already in use in some of the drug-grinding establishments in town, and is made to prepare cinchona-bark, calumba, gentian, etc., in a fit state for infusion, without making any dust.

"Ignoramus."—(1.) No. (2.) Yes. (3.) The Major and Minor examinations are held only in London and Edinburgh; the Preliminary examinations may be conducted under the superintendence of the Local Secretary of the district most convenient to the candidate.

"Amico."—The Minor examination is entirely *vivâ voce*, and is of only one day's duration. With regard to the Major examination, particulars should be sent to the Secretary, at 17, Bloomsbury Square.

R. Keevill.—Your letter has been handed to the Secretary. See a notice on p. 2 of the advertising sheet as to the occasional delay in the delivery of the Journal.

A. M.—The temperature may be raised to any point, provided that the water is under sufficient pressure.

Ph. C.—By section 1 of the Pharmacy Act it is made illegal for any person not registered under that Act to assume the title of "Druggist."

"Inquirer."—See a case reported in this Journal, 3rd ser. Vol. I. p. 775.

THE ACTION OF NITRIC ACID UPON NATAL ALOES.

BY WILLIAM A. TILDEN, D.SC., F.C.S.

In the course of reading the interesting paper of Professor Flückiger upon the "Crystalline Principles in Aloes," presented at the last meeting of the British Pharmaceutical Conference, and recently published in the PHARMACEUTICAL JOURNAL, I was struck with one statement which appeared to me extraordinary. It was to the effect that his "nataloin," when treated with nitric acid, yielded nothing but oxalic acid, and that though sought for, picric and chrysammic acids were not to be found. I regard the aloins as bodies belonging to the class called phenols,—in fact, a kind of orcin, though unquestionably of a complex and highly condensed type. It therefore, seemed to me improbable that nataloin, whilst agreeing with other substances of the same family in general characteristics, should so far differ as not to give a nitrated acid of some kind. I therefore procured a small quantity of Natal aloes, and prepared from it the crystalline principle according to Flückiger's directions. His description of the physical characters of this substance appear to be correct. Three grams of perfectly pure nataloin, which had been several times crystallized from rectified spirit, were dissolved in about ten cubic centimetres of pretty strong nitric acid, and, when the first violent action was over, the now orange-coloured liquid was digested in a flask for two or three hours, it was then turned into a dish and evaporated to dryness. A mass remained, which was evidently chiefly oxalic acid, but was tinged intensely yellow; it was put back into the flask with a small quantity of fuming nitric acid (sp. gr. 1·45) and warmed gently till all action seemed to be at an end. The liquid was once more evaporated to dryness. On treating the residue with water it gave a solution of a bright golden colour, which dyed silk yellow. Warmed with cyanide of potassium, it gave a blood-red liquid, and, when boiled with chloride of lime chloropicrin, unmistakable from its frightful odour, was evolved. Shaken with lime and ferrous sulphate, a red liquid was produced. The remainder of the residue was mixed with solution of potassic acetate and allowed to stand; next morning tufts of orange needles were deposited. These were found to be explosible, and when boiled in water and mixed with ammoniacal cupric sulphate, the characteristic green precipitate changing, on boiling, into yellowish scales was produced. These reactions indicate, beyond doubt, the formation of *picric acid*, but as I had not enough material from this experiment to analyse one of the salts, I treated some of the crude drug with nitric acid. This requires some caution, as with nitric acid of sp. gr. 1·37 the action is very energetic, and a great deal of frothing occurs in the early part of the process with production of a large quantity of a ruby-red resinous substance. When this, however, is digested for some time with nitric acid, assisted, towards the end, with a little fuming nitric acid, an oily substance results, which solidifies, on cooling, into crystalline masses. These treated with boiling water dissolve, forming a bright yellow bitter solution, which, after neutralization with potassic carbonate, deposits, on cooling, a magnificent crystallization. These crystals are but slightly soluble in water, but may readily be crystallized from boiling water. Long lustrous prisms are then obtained, which present all the appearance and characters of potassic picrate. Analysed, ·5420 gram dried at 230° F. gave ·1735 of potassic sulphate, which corresponds to 14·33 per cent. of potassium. Picrate of potassium, $C_6H_2(NO_2)_3KO$, contains 14·60 per cent. of potassium.

The action of nitric acid upon nataloin yields, therefore, both oxalic and picric acids.

A CHAPTER IN MICROSCOPY.

BY HENRY POCKLINGTON.

The author of a certain book on the microscope tells a tale of a person who purchased a first-class microscope from one of the then principal manufacturers in London, but a few days after desired to return it, with the remark that he had tried it and found it perfectly useless, because it would not even show the crystals of sugar. In reply to an interrogation as to how much he had tried to look at, he said, "Oh, a good big lump from the sugar basin!" However much an experienced microscopist may be disposed to laugh at such crass ignorance of the proper way of using the microscope, the purchaser was to be pitied if he had become the possessor of a costly instrument without having the least notion as to how the thing was to be used, or for what purpose its several parts were designed. And there is no doubt, that amongst the many possessors of an instrument which now bids fair to be as fashionable a piece of furniture in a well-to-do household as a pianoforte, there are many whose ideas of how to use it are in a state not so unlike that of our lump-sugar friend, and who may not be indisposed to be thankful for a few hints as to what to do and what not to do.

The initial difficulties in the use of the microscope are not very great; a few minutes, or, at any rate, hours, will suffice to overcome them. In the higher walks of microscopy the case, as we shall see later on, is somewhat different. But as the tyro must walk before he can climb, he need not trouble himself by looking so far ahead.

We will assume that the microscope has been purchased:* not a big showy stand unfit for rough every-day work, but such a student's as any maker will sell nowadays for £5, £10 or £20, according to the apparatus required therewith: and has been brought home, unpacked, and the happy purchaser only too anxious to delight the eyes of his wife with the wonderful "revelations of the microscope." He will probably have learned the names of its several parts, and how "to put them together." At all events, he ought to get this much information from the maker of the instrument, and to be prepared to listen to us with his microscope *en règle*.

The first question to consider is that of the light to be used. Books are agreed as to this. Daylight being, according to them, by far preferable to any artificial light; yet, by far, the majority of microscopists use artificial light for their researches,—partly from compulsion, because their day-time is occupied by other pursuits, called by a microscopical friend butter-bread business, but also because a

* Big microscopes are not to be despised by those who can afford them, and who range the higher fields of research. Our remarks apply only to beginners.

movable lamp is under more perfect control than daylight can well be, and is also in this England of smoke and cloud more to be relied upon for constancy. Whichever be used, the light should fall upon the instrument from the left-hand side, if the observer use his right eye chiefly (as most do); and from that side in any case, if there be many adjustments to be made of the illuminative apparatus, which, being made with the right hand, would cause a disagreeable shadow were the light allowed to come from that side. By daylight care should be taken that the direct rays of the sun are not allowed to fall upon the object. Light from a white cloud opposite to the sun, or nearly so, is best; that from a *blue* sky is wholly unfitted for micro-polariscope work, as it is chiefly composed of light already polarized in one plane, and, therefore, only transmissible through one direction of the polarizer.

Lamps.—Their name is legion. We cannot advertise them all. Personally, we prefer an ordinary paraffin lamp, which need not cost more than a couple of shillings, or, including Mr. Swift's Blankley's new chimney, about five shillings. Such a lamp embodies nearly all the advantages of the most elaborate, and is not an addition to the paraphernalia which so often disturbs the mind of one's better half when his microscopical laboratory happens also to be his or her sitting-room. The addition to the lamp of a piece of glass stained to a decided neutral blue tint is very pleasing, and gives great relief to the eye, as most of the yellow rays that are so disagreeable and wearying are stopped back. But if such be used, it is needful to use a larger flame than would be otherwise needful. Gas is, in our notion, simply hateful for microscopic purposes, on account of its great unsteadiness, heat and its products of combustion.

Seated then at the table, not too high as to necessitate the craning of the neck, nor so low as to cause an ugly stoop (upon all these *little* things success in microscopy is dependent to a greater extent than is commonly recognized by even experienced microscopists), with the light of his lamp well adjusted, to avoid either smoke or glare, and the lamp a little to his left, the tyro may begin to work.

He cannot do better than familiarize himself with the varied effects produced upon some homely object, such as a section of wood, by direct and oblique light falling at different angles. In other words, he should begin by learning the use of the mirror, used with those objects which are sufficiently transparent to allow light to pass through them, and the bull's-eye condensing lens, used to throw light upon those objects that are too thick or otherwise too opaque to be viewed as "transparents." One of the earliest lessons we hope he will learn will be that too much light renders it difficult or impossible to see the details of an object, especially if low powers be used. From this he will learn to alter the focal adjustment of the mirror or condenser, by moving it nearer to or further from the object under view, and also that the intelligent use of the several apertures in the diaphragm plate will greatly aid him in his efforts to obtain just so much light, and no more, than is necessary. Collins' iris diaphragm, if he be so happy as to possess it, will place literally, as well as figuratively, at his finger-ends, through a few turns of a milled head, the means of doing this to the greatest possible nicety. Having become thus far conversant with the "go" of the microscope, our friend may safely begin to think of entering upon that particular department of microscopic work into which choice, or the fates, may happen to call him. That is to say, having become master, to some extent, of the instrument, he may proceed to learn how to prepare objects and fit them for observation. Here, however, we cannot at this moment attempt to help him, as we want to say a few words to him and to more advanced microscopists respecting *their* part of microscopic work.

There is, perhaps, no branch of science in which what astronomers call "personal errors" more abound, or where the poet's aphorism, "things are not what they seem," is more applicable. A few of these "errors of interpretation" may be briefly noticed.

1. *Foreign matter.*—The presence of foreign matter in the preparations of young, and especially careless microscopists, is the source of great perplexity, and the fruitful cause of wrong conclusions. Perhaps the most frequent of these are air bubbles. All beginners in microscopy are perplexed with these; the more so as they are often the most prominent features in even good slides by very experienced men. Usually a very little experience will enable the observer to decide as to the nature of the queer-looking black rings with bright centres that he sees in the field; but there are cases where,—the bubbles being exceedingly minute and confined within a delicate tissue, which alters their shape, and consequently their refractive power,—it becomes somewhat difficult to decide upon their nature. It is, under these circumstances, a matter of great care and skill to decide whether the appearance is due to the presence of air, of oil, or, in some cases, of water. The question, if solved at all, will be solved by careful observation of the effect produced by *alteration of focus.* The milled head of the slow movement must be turned very slowly until the objective is *raised* out of focus, and then reversed until it has been *depressed* out of focus. Oil globules become *lighter*, as the objective is *raised*, and darker as it is depressed, whilst water globules and air-bubbles, surrounded by oil or balsam, do exactly the reverse. The explanation is, of course, to be found in the very different refractive powers of the three substances. In the case of the oil globule in water, the globule acts as a *convex* lense of short focus, the other globules acting as concave lenses. In the examination of vegetable and pathological preparations, it is often of essential importance that the observer should be able to detect the difference between a vacuole, an air-bubble, fat or resin globule; and no pains spent in becoming familiar with their several appearances will be regretted. Particles of "dust" are also the source of frequent error, and we would strongly urge the student to acquaint himself with the microscopical appearance of such substances as compose the ordinary "dust and flue" of his rooms. The nature of this pest to housewives varies so much in different localities that we cannot particularize *all* its ingredients. The following are the most perplexing:—butterfly scales, starch granules, portions of wood fibres, hairs, cotton and wool fibres, leaves, fungi spores, and, by no means least, excessively minute particles of soot and other mineral matter. Nothing but experience will serve the student here, and fortunately it is easily and inexpensively gained.

(*To be continued.*)

COD-LIVER OIL, ITS MANUFACTURE AND COMMERCE.

BY P. L. SIMMONDS.

The trade in cod-liver oil has become an important and thriving one, and is evidently increasing with the advance in prices of late years. Our average imports, taking the last three years as a criterion, are about 890 tuns,—the following figures giving the official imports and computed real value. The returns for 1870 and 1871 are not yet published.

1867 . .	818 tuns,	worth	£52,163.
1868 . .	843 ,,	,,	56,878.
1869 . .	1011 ,,	,,	75,081.

The bulk of the oil received is pretty evenly divided between the two great seats of the cod fishery, Norway and Newfoundland, although the former is now taking the precedence in production.

The following are the relative proportions and prices:—

Imports from Norway.

		£.	s.	d.
1867 . .	322 tuns, price	63	1	0
1868 . .	399 ,, ,,	68	5	0
1869 . .	399 ,, ,,	75	11	0

Imports from British America.

		£.	s.	d.
1867 . .	227 tons, price	63	16	0
1868 . .	233 ,, ,,	68	0	0
1869 . .	327 ,, ,,	74	8	0

It is strange that our merchants and fishermen at Newfoundland have allowed the Norwegians to trench so largely on this manufacture, for there has been no increase in the export from Newfoundland, which stood at 327 tuns of refined cod-liver oil in 1857.

From the above figures we see that the medical employment of cod-liver oil has attained to grand proportions with ourselves, whilst its use has also become very general in Europe, America and our colonies.

The livers intended for preparing the medicinal oil are first washed and dried, and then, after a careful examination, to see that there is no gall left in them, they are placed in tinned iron pots. These are again placed in larger pots, and steam being circulated between them from a furnace, the liquefaction gradually proceeds. Some makers substitute hot water for steam, alleging that it is easier to regulate the temperature; others allow the steam to enter the pots which contain the livers. As the melting proceeds, the oil is removed by larger ladles and left to cool. It is filtered once or twice and poured into barrels, when it is ready for shipment. The parts which do not readily liquefy, or which remain after filtration, are left in the pots and further heated, until they acquire a deep brown or olive colour. The brown oil thus extracted is employed by curriers, and the residue or deposit forms a useful fertilizer for land. The fishermen who prepare the livers on their own account merely place them in casks or vats, and let them dissolve naturally, collecting the oil which drips. The first oil thus obtained is the clearest, and of a pale straw colour. It is to this the name of "superior white" is given. If the flavour is good, it is employed for medicine. In some countries it is even preferred to the medicinal oils obtained by steam. The second collection yields "ordinary white" oil of the colour of Madeira wine, and the third a clear brown oil. It is this quality which is sold under the signature of Dr. de Jongh, of the Hague. The residue or deposit is heated, as in the steam factories, to obtain the common brown oil for curriers, so largely used in the leather manufactories of Holland and the North of Germany.

The best kinds of steam-prepared oil are shipped in tinned cases, and occasionally in oak barrels, as the ordinary kinds of oil are. But in Finmark, if the fishing is abundant, they are obliged to ship in fir casks.* The export of all kinds of fish oil from Norway, which usually averages 7,000,000 or 8,000,000 litres, was in 1866 nearly 10,500,000 litres.

One method of making cod-liver oil is thus described in the report of the Select Committee on the working of the Fishery Act of Canada:—The apparatus is simple and inexpensive, consisting of a box made of common boards, which may be lined with tin, as being more easy to wash; a cloth is laid inside the box and upon this the livers are placed; the box is provided with a closely-fitted solid cover. A pot, holding forty or fifty gallons, with a tight-fitting wooden lid, is placed some feet from this box, and a wooden pipe or tube leads obliquely from the lid, and communicates with the box in which the livers are. Twenty-five or thirty gallons of water are put into the pot, and the steam entering the box, eliminates the oil and water resulting from the contents. A barrel is placed beneath the centre of the box, in which a hole is pierced to permit the oil to escape. After the steam has been allowed to remain in the box for two or three hours the cover is removed, the livers stirred up, and a little salt thrown in to precipitate the strong parts of the liver. The contents are allowed to settle for five minutes, after which the oil which comes to the surface is removed. The box is then closed again, and the process repeated every hour. This must be carefully carried out, in order to obtain white and sweet oil of the best quality. When it is apparent that no more oil remains in the livers, they are exposed to the sun, and become fit to be used in making soap. By this method, from the same amount of livers, more than double the quantity of oil is obtained than from the former crude processes; from a cask containing thirty gallons can be extracted fifteen to seventeen gallons of oil of the best quality.

At St. Pierre and Miquelon, where the French share in the Newfoundland cod-fishery, a considerable trade is carried on, not only in the common cod-oil of commerce, but in refined cod-liver oil. The former is simply obtained by the fermentation of the livers in casks placed in the holds of the fishing-vessels, or on shore near the dwellings. About 500,000 kilogrammes a year are shipped of it.

The preparation of brown and white medicinal oil at St. Pierre is becoming an object of much importance, and has been encouraged by the Paris Academy of Medicine, who state that the brown, pale and white oils of the French fisheries of Newfoundland equal the best products of the Norwegian and

* 'Les Pêches de la Norwége,' par Herman Baars.

English manufacturers. That which is made in the months of April, May and June is considered by the French the best, as the livers are then lean, later they become too fat, and yield a less useful oil in a therapeutic point of view.

On the Norwegian coast the catch of each boat varies in the yield from eight to twenty barrels of livers. The fish in the early part of the season are rich in liver, so that from 250 to 300 of the net-caught fish give a barrel of liver, while 50 to 100 more of the fish taken on lines are required. As the season advances, the fish become perceptibly poorer, from 400 to 450 being required to fill a barrel; while on the seaboard or western side of the Lofoden Islands from 600 to 700 are necessary. On the whole, therefore, it may be assumed that the average number of 450 livers is required to fill a barrel. The total produce of cod-liver oil from the Norwegian fisheries in 1869 was estimated at 19,000 barrels, and good marketable roes 17,000 barrels. 200 barrels were prepared as medicinal cod-liver oil. Fresh livers for medicinal oil fetched from 27*s.* to 31*s.* per barrel, old livers from 22*s.* to 26*s.*, and cod roes from 32*s.* to 35*s.* per barrel.

A long and interesting article on the manufacture of cod-liver oil in Norway, by Mr. Peter Möller, a chemist of Christiania, was published in my *Technologist* for 1862 (vol. ii. p. 376), from which I extract the method he recommended to be pursued:—

"The liver is taken as fresh as possible—that is, as soon as it is taken out of the fish,—and is then washed and cleaned with water, and the gall-bladders removed; it is then cut up into small pieces, and thrown into the kettle. When this is nearly two-thirds full, the fire is lighted underneath, and the water in the kettle is brought to a boiling state, and must be kept so as long as the process of melting lasts. The whole mass must be constantly stirred, and pressed with a large wooden spoon, in order to promote the separation of the oil, which as it liquefies is gradually poured into a cask through a strainer.

"The process must be continued in this manner till all the oil is extracted from the livers. The remaining portion of the liver is then taken out of the kettle and laid on one side, in order to yield the brown or currier's oil, after the manufacture of the best and purest oil is completed."

In good years from 12,000 to 16,000 casks of both sorts of oil are exported from Norway a large portion of which is employed for medicinal purposes.

(*To be continued.*)

PHARMACY IN EDINBURGH IN THE OLDEN TIME.*

BY JAMES MACKENZIE.

Gentlemen,—The subject which I now intend bringing before you, viz. "Edinburgh Pharmacy in Olden Times," is one fraught with much interest to all who are engaged in the study and prosecution of this science, exhibiting as it does the rise and progress of pharmacy in our good old city during the last two or three centuries. The circumstances which seem to have conduced to its most primitive existence, are more complicated, obscure and curious than one could well imagine at first sight. A knowledge of medicines and the mysteries which have ever shrouded their preparation, dates from the earliest time. To relieve disease by the use of such means is associated with Christianity itself; hence, for long ages, we find it connected with various ecclesiastical bodies, being then considered an inseparable part of their education and calling. While there was much to recommend its being thus associated, we have good reason to believe it was often used for sinister purposes.

At the very outset, however, we are reminded that pharmacy had for long ages been associated with the "healing art," and the difficulty is to ascertain the exact date when it had a separate existence. On that account we are obliged to consider our subject in its collective capacity, and try to follow it throughout the many changes which records of its history call to mind.

From what we are able to gather, there has ever been a desire amongst the learned and unlearned to try the practice of this science. Here we must notice the fact that wherever ecclesiastical edifices of any importance existed, there the monks and members of the clergy were found pursuing the alchemical art, for the primary purpose of discovering that eagerly-sought-for prize, "the philosopher's stone," which was to transmute all base metals into gold. That, of course, was a fruitless search, but it resulted in the discovery of much that was unknown in chemical science, so that these men, though in pursuit of so absurd an object, were unintentionally laying the foundations of pharmacy, and are the reputed discoverers of some of those chemical preparations which hold no unimportant place in our day,—I refer to such substances as calomel, antimony, etc.

We have, on the other hand, the herbalists,—he or she, as the case might be,—who practised the "healing art" by the application of all manner of vegetable substances. Here, also, mystery was carried to a great extent. The place where such herbs grew, and the particular ray of the sun or moon which must shine on them during the process of gathering, were all matters of the greatest importance; indeed, it was imagined that inattention to such particulars would retard or destroy all the virtue these herbs were thought to possess.

During the fifteenth century, however, a great change passed over Scotland and her capital. There was a reformation in ecclesiastical matters, which extended to many other departments, and, amongst these, pharmacy had its share. A new generation of men sprung up, who appear to have held a position between the former extremes, and who practised surgery in its ruder forms. To this, pharmacy was added as a necessary part; but, not content with that, they were incorporated with the barbers,—to us a strange and laughable combination. Here we may notice that even to the present day, some barbers exhibit a pole and plate above their door, the recognized sign in olden times that bleeding and bandaging were done by them. In our Council Register we are informed that, "On the 5th day of July, 1505, the surgeons being the first company of craft in Edinburgh, they, according to the custom of other European nations, were incorporated with the barbers, by charter." This record or charter contains a full and particular account of their several duties and requirements. In one clause we find the following:—"That na person, man or women, within this burgh, mak or sell ony *aqua vitia* within the samyn, exceptis the said Maisters, Brithers and Freeman of the said craftis, under the payne of escheit of the samyn, but favour." Thus we see whisky was, in 1505, recognized as a pharmaceutical preparation, only to be made and sold by the surgeons. How strangely does the wisdom of our forefathers, in this respect, contrast with the foolishness of their sons! The above charter was confirmed by James IV., on the 13th of October, 1506, and Queen Mary, in consideration of the close and necessary attendance of the members of the Corporation on their patients and studies, did, by her letters patent of the 11th of May, 1567, exempt them from attending juries, watching and warding within the city and liberties of Edinburgh. These grants were confirmed by James VI., on the 6th of June, 1613, as they likewise

* Read at a meeting of the North British Branch of the Pharmaceutical Society, Edinburgh, November 24th, 1871.

were by Parliament on the 17th of November, 1641. Upon application to the Common Council of Edinburgh, they, by their Act of the 25th of February, 1657, erected the surgeons and apothecaries into one community, which, with former privileges, were confirmed by Charles II. and ratified by Parliament on the 22nd of August, 1670, as they were some time after, by letters of William and Mary, of the 28th February, 1694, with an additional grant to practise within the counties of East, West and Mid-Lothians, the shires of Fife, Peebles, Selkirk, Roxburgh and Berwick, which was confirmed by Parliament on 17th July, 1695.

The arts of surgery and pharmacy being thus united, the Corporation laid aside the barber craft, which occasioned the Common Council, by their Act of the 26th July, 1682, to recommend to the Company to take care to supply the town with a sufficient number of persons qualified to shave and cut hair, on such terms as they could best agree on, and that the said persons should be held as dependants on the surgeons, which was accordingly performed, and so continued till the 23rd February, 1722, when the Court of Session, by their decree of this date, separated the barbers from the surgeons in all respects, other than the barbers are obliged to register the apprentices with the surgeons, and to be admitted by them and the barbers. Now the barbers being forbidden to practise surgery, the Common Council in lieu thereof, allowed them to make a spirituous liquor, called aqua vitæ.

In 1621, we find the first mention of apothecaries in Edinburgh, in connection with an order by King James VI. to the Parliament, for a College of Physicians there. Here, then, we find the nearest approach to pharmacy, as a distinct branch, which the well-meaning physicians intended to look after, by proposing to have three of their number set aside for this purpose. Fortunately, however, for the apothecary, this order never became law, though repeated attempts were made by them to gain their purpose. It is evident by this time, that a distinct body of men had begun to practise pharmacy, apart from the surgeons, barbers and physicians, yet practising some of the minor operations in surgery, under the designation of apothecaries. This appears to have been the result of circumstances, more than anything else; at the same time the physicians and surgeons rose in their own and the public estimation, just in proportion as pharmacy was left to the apothecaries. Yet the physicians felt this new arrangement most galling, and were loth to see the apothecary acting independently. We see the progressive development of pharmacy, in the draft of certain particulars which the physicians wanted, when in 1630 they applied to King Charles I., in a renewed attempt to obtain a charter for a college. Here first mention of druggists—or drogists, as they were then called—is made. Then, in 1656, the physicians once more renewed their application to Cromwell; and in the memorial drawn out for this purpose, the druggists are again referred to, and on this occasion they seem to have risen somewhat in the social scale, because they are named before the apothecaries. Whether this was caused by their superiority, or greater troublesomeness to the physician, is not known. It is evident, however, that jealousy was very strong amongst all grades connected with the "healing art." When we look back to the list, which includes the monk, herbalist, surgeon, surgeon-barber, apothecary, physician and druggist, we, as pharmaceutists of the present day, may form some idea of our origin, and the associations connected with pharmacy in Edinburgh.

I will now read some extracts from the Council Register, which will convey to you some notion of the exactions attempted to be enforced upon the pharmaceutists by their brethren in the higher grades of the Esculapian art, which were, however, no more successful than were similar attempts made in this direction during the present year.

The following is an order of King James VI., dated July, 1621:—

"Commissionaris, and Estates of Parliament, we greit you heartilie well,

"For sae meikle, as we are certainlie informet, of the gryte abuse done and practised; be ane number of ignorant and unskilfull persons, quha without knowledge of the sciense and facultye of medicine, being nather learned nor graduat therein, presumes at their awen hand to profess and practice physick and medicine to the gryt and evident hazarde and danger of the lyffes and healthes of many of our subjects, quhilk evill is becume so ryff and frequent, that the samyne is lyklie to produce great harme and detriment, except the samyne be tymouslie prevented," etc. etc.

The order goes on to describe the nature of the constitution of the College, how its professors were to be elected, etc.; but the doctors could not venture, even at this date, to leave the poor druggists out in the cold, with no one to look after them, so they provided that warrant be given to the said College and Incorporation, "To make choice yierlie of three of their number, who sall have the cair and charge to searche and try the freshness and sufficiencie of all drogges, wares and medicaments, being within all and whatsumever apothecaries choppes, within our said burgh of Edinburgh, and gif they be found corrupt and insufficient, to destroy the samyne, and that ye sett down penalties against the refusers or contraveners of the said statute," etc.

"Given at our Manor of Otelandis, the third day of Julie, 1621."

The following is attached thereto:—

"This conteynes your Majesties warrant to the Commissionaries and Estates of Parliament, for the erecting of a colledge of physicians, and prohibiting wemen and ignorant persons practising that arte in Scotland.

"Signed, George Hay, 2nd August, 1681."

It has been truly said, history repeats itself. How strangely does the reading of the restrictions in the above sound in our ears, after what has so lately happened! Though 250 years have come and gone, yet the order of 1621 had much the same fate as the intended Bill of 1871.

The wise and gracious purposes of King James were therefore frustrated, and it is strange to notice the means which were used in those days to accomplish this. It was through the influence of the clergy. The bishops saw their prescriptive privileges were thereby affected, and suspected, whether justly or not, that the physicians, as to their religious or rather their ecclesiastical opinions, had too much sympathy with the popular party, who were not favourable to the episcopal rule. The corporation of surgeons were also alarmed for their own privileges, and very readily lent their co-operation to defeat the design of the physicians. In 1630, the physicians of Edinburgh again renewed their attempt to obtain a patent. Their application this time was to King Charles I., who referred the matter to the consideration of the Privy Council, who in turn ordered the physicians to give in some heads and articles for the erection of a college, which they did in 1633. From these articles it appears that, not daunted by their former want of success, they now demanded greater powers and more extended privileges, and proposed that the institution should have, not a local character and jurisdiction merely, but national. As in former days, however, opposition was raised from the old quarter, hence obstruction and delay resulted.

But, to give you some notion of what they proposed to do with the druggists and apothecaries, over and above looking after themselves and the surgeons, I will read a few extracts from some of the articles which they drew up:—

"Article 5th.—That power be granted to all the particular societies of medicine, of the foresaid incorporation, to appoint yearly, at what time it sall be thought by the said societie most expedient, two censors of their number having with them ane apothiquer of the towne of their residence, to view, try and examine the sufficiency of all medicaments, drogues, compositiones, waters, oiles and chymicall preparations, and to report to the said societies, to the end that whatsoever sall be found by them to be either adulterate or corrupt and carious, may be by them ordeaned to be destroyed and cassed, without any hinderance to be made for that effect be any apothiquer, drogist or sellers of insufficient droges.

"Article 6th.—That power be granted to the said colledge, with the concurrence of two apothiquers whom the said colledge sall please to nominate, to tax and appretiate yearly all drogs, medicaments and compositiones, waters, oiles, and all which be in use to be employed; and that it be ordered that publick records of the severall taxes and appretiationes be made, whereof ane copie sall remaine in the custodie of the said colledge, and every apothiquer sall have ane publickly extant in his buith, that the buyers may have knowledge and insight of the prices, and to fine the exceeders of the said taxes proportionallie to the quality thereof.

"Article 7th.—That prohibition and defense be made to all the apothiquers and droguists, and to all others within the kingdom, to sell any drogues of dangerous quality,—as antimony, opium, scammony, arsenic, mercury, sublimat, hellebore, elaterium, or any narcotic, cathartick, or purging medicaments,—to any whatsoever, except alternately either to the apothiquhers or to the physician of the forsaid incorporation, or licentiats from the said colledge, or to such others as has their warrant and ordinance for the same, with power to the said colledge to fine the delinquents."

Then it goes on to say that these articles are to be "oppenly proclaimed at the mercate crosses within this realme, and be printed by the king's majesties printer, to the effect that none pretend ignorance."

(*To be continued.*)

PRESENCE OF MILK-SUGAR IN A VEGETABLE JUICE.

BY G. BOUCHARDAT.*

By extracting sugar obtained from the juice of the sapodilla (*Achras sapota*) with boiling alcohol, a crystalline substance is obtained, which, after being twice recrystallized from water, possesses all the properties of milk-sugar. It is hard, crunches between the teeth, is slightly sweet, melts at 204°, and gives off gas if this temperature be maintained for some time; it is soluble at the ordinary temperature to the extent of about 14 parts to 100 parts of water, and its solution rotates polarized light to the same degree as milk-sugar; heated with potash it turns brown; it reduces potassio-tartrate of copper, but does not undergo alcoholic fermentation by contact with beer-yeast under ordinary circumstances; it is precipitated by ammoniacal acetate of lead, and when treated with five times its volume of dilute nitric acid produces a certain quantity of mucic acid.

The mother-liquor from which the above substance is obtained yields crystals possessing all the physical and chemical properties of cane-sugar.

The relative proportions of cane-sugar and milk-sugar in the substance employed are as 55 to 45.

The author also states that on treating the extract juice of ripe sapodilla fruit with acetate of lead, precipitating the saccharine matters with ammoniacal acetate of lead, and decomposing the precipitate with sulphuretted hydrogen, the filtered liquor concentrated to a syrup, purified by solution in alcohol, and subsequently treated with dilute nitric acid, readily yields crystals of mucic acid.

* Compt. Rend., lxxii. 462–464, from the *Journal of the Chemical Society.*

THE YELLOWSTONE VALLEY.

Professor Hayden, who has been engaged for four years on a geological survey of the United States' territories, has returned to Washington, and will proceed to prepare his annual report, which will include the survey of the famous Yellowstone Valley. The expedition to that valley left Utah in June, and explored the belt of country to Fort Ellis, Montana, proceeding then into the Valley of the Yellowstone. Professor Henry, Secretary of the Smithsonian Institution, has received a letter from Mr. Elliott, the artist who accompanied the expedition, giving an account of the "Great Cañon," a huge basaltic fissure or rent in the earth, beginning at Tower Creek and ending at the foot of the Lower Falls of the Yellowstone. Hence, it is 25 or 30 miles long. The cañon varies from 1000 to 2000 feet in depth, and along its bottom the river whirls with immense velocity, appearing from above "now a blue and now a snowy riband." The attrition of the stream for ages has worn the sides of the chasm into strange shapes of "towers, points, and pinnacles," and these are "gaily painted by the waters of the numberless warm and hot springs which ooze out from the fissures into a variety of tints and tones, dazzling white, intense red, purple, saffron, yellow, etc., and fairly bewildering the eye, at first, by their singularity and grandeur." The cañon is, moreover, fringed in some places with rows of basaltic pillars, quite regular in form, from 20 feet to 30 feet high, and standing, without crack or flaw, in regular tiers one above the other. The great Falls are more imposing still. They are a "broad, evenly deep sheet of clear ice water, leaping down at one bound 450 feet." Unbroken by any point or division, they rush over the ledge, a vast curtain, as of swift, foaming lace. These are the Lower Falls, the Upper being just the height of Niagara, or 150 feet, and but half a mile distant from the other. Thus, within that short space, the stream makes a descent of 600 feet. But the chief marvel of this section would seem to be the "Geysers of the Firehole Basin." These are at the headwaters of the Madison, and in magnitude and extent of area reduce the famous boiling springs of Iceland to complete insignificance. Mr. Elliott writes:—"I have stood by a crater, and have seen a column of hot (boiling) water six feet in diameter ascend with a single bound, vertically, to a height of 200 feet; pause there for an instant, and fall to its silicified basin in a thousand water streams and a million prismatic drops. This continued for ten or fifteen minutes; then all would be quiet; the water of the cistern became as still as that of a mill-pond, and apparently as inactive. This geyser, which is one of many, we named the Grand. It plays at irregular intervals of twenty-four to thirty hours for ten to twenty minutes. Another, named by Doane 'Old Faithful,' plays at intervals of only an hour apart, throwing up an immense steady column to an elevation of 150 feet." There are fifty geysers and over a thousand boiling springs, according to this authority, within 50 miles of each other; and it is evident that these objects must rank among the wonders of nature.—*Times.*

CARBOLIC ACID PILLS.

The following formula for carbolic acid pills is taken from the *Journal de Pharmacie et de Chimie*:—

Carbolic Acid	3 drops.
Soap Powder	0·60 gram.
Lycopodium	0·06 „
Powder of Gum Tragacanth .	q. s.

For six pills. The first two ingredients make a semifluid mass that the lycopodium does not absorb, but which acquires firmness upon the addition of the gum tragacanth.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 2, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE CHICAGO CATASTROPHE.

"Our pharmaceutical brethren in Chicago have lost by the great fire their College, with its library, lecture-specimens, apparatus, herbarium and furniture." This is the first sentence of a letter from Professor Attfield, published in our correspondence column this week, and to it, as also to the interesting letters of Professor Ebert and Mr. Brady, we call the serious attention of our readers.

So much has been written by the general press about this awful conflagration, and so much public spirit exhibited by our countrymen, that we refrain from picturing the terror and ruin which a calamity so unparalleled must necessarily have inflicted on our English-speaking and warm-hearted brethren of the far West of America.

During the few weeks that we, as a nation, have been cheerfully performing the duty of assisting, in common with other European States, to lessen the widespread misery which this fire has induced, thoughts as to the position of the burnt-out pharmacists of Chicago have, doubtless, passed through the brain of many a druggist on this side of the water.

The letters to which we have referred describe precisely the pharmaceutical situation in that unfortunate city. Its Alma Mater, reared with loving hands and proud hearts, and full of expensive educational appliances, a heap of ruins; the businesses and all the property of six of its wholesale, and forty-six of its retail druggists lost; and the local means of raising the College from its ashes completely cut off.

Under these circumstances we cannot be surprised that through Mr. Ebert, one of its professors, and well known personally to many in this country, British pharmacists should be asked to assist in reinstating it. He conjectures, and in our opinion rightly, that colleges of pharmacy, wheresoever situate, spreading broadcast scientific and practical knowledge, and thus benefiting the profession throughout the *world*, may, in an exceptional case, such as the one under notice, fairly claim some consideration from *every* member of it.

We are sanguine that he will meet with a generous response. Already the President of the Pharmaceutical Society (Mr. Haselden), the Treasurer (Mr. Hills), the President of the British Pharmaceutical Conference (Mr. Brady), and Sir Thomas Dakin (the late Lord Mayor of London), men representing every section of the trade, have willingly consented to act with Professor Attfield as the nucleus of a Committee for collecting books, specimens, apparatus, etc., and funds with which to purchase others.

Parcels, cheques (crossed London and Westminster Bank), and Post-Office orders (payable at High Holborn) will be gladly received on behalf of the Committee by Professor Attfield, 17, Bloomsbury Square, London, W.C., and duly acknowledged in this Journal.

THE REGISTER.—SPECIAL NOTICE.

We have on various occasions called attention to the necessity that every person entitled to be on the Register of Chemists and Druggists should make it his personal business to see that his name and address are correctly given. We are requested by the Registrar again to urge the importance of this matter, and to say that as the Register for 1872 is now in preparation for printing, it is requisite that notice of any former errors, or changes of address since the last issue, should be forwarded *at once* to him at 17, Bloomsbury Square. Local Secretaries also are requested to forward information of any changes that may have occurred in their districts during the year.

As this Register is now the only legal evidence of the right to carry on business as a chemist and druggist in Great Britain, it is important that every entry upon it should be correct, but such accuracy is not attainable without the assistance of all concerned.

SPURIOUS TEA.

At the meeting of the City Commission of Sewers, on Tuesday last, a report was presented from the Sanitary Committee on the subject of the seizure of spurious tea, which well illustrates the present defective state of the law in reference to the adulteration of food. It stated that, upon a full consideration of the circumstances of the most recent seizure, the Committee did not think it expedient to take legal proceedings against the offenders,—experience in past cases giving them little encouragement to do so. They were of opinion that the traffic could be stopped only by the officers of Her Majesty's Customs, and that no local sanitary authority, even if armed with fuller legal powers, would be able to deal with it successfully. They had written to the Secretary of the Board of Customs on the subject, who told them that the officers of that department were not empowered to seize and destroy tea, whether spurious or not, even upon a certificate that it was unfit for human food. They then had an interview with the President of the Board of Trade, who intimated that the Board had no power over the Customs and referred them to the Lords of the

Treasury. They next had a conference with the Chancellor of the Exchequer and Sir Thomas Fremantle, the Chairman of the Board of Customs, but with no better result; both those gentlemen being of opinion that even with qualified inspectors locally appointed, the Customs could not be entrusted with such powers as those suggested, and that such powers if used would have a very injurious effect upon trade, and divert a large amount of business from this country. The Chancellor of the Exchequer considered that nothing further could be done without an express Act of Parliament, and that any application to the Government to introduce such a measure, which probably would not pass, should be made either to the Home Secretary or the Local Government Board. The Committee concluded by expressing regret that there seemed no means open for adoption likely to put a stop to a trade so injurious to the health of the community. The Report of the Committee was approved and ordered to be printed and circulated among the members of the House of Commons and of the Corporation and of the various sanitary bodies in the Metropolis.

The usual Monthly Evening Meeting of the Pharmaceutical Society will be held on Wednesday next, at half-past eight o'clock. The first subject will be the discussion on Mr. Greenish's paper on "Pharmacy in North Germany," adjourned from last month. Professor Redwood's paper on "The Substitution of Proportional Numbers for Specified Weights and Measures in the Description of Processes in the Pharmacopœia," which also stands over from last month, will be the next. A paper by Mr. J. T. Miller on a "Method for the Estimation of Morphia in Opium," and another by Mr. A. F. Haselden, on "The Syrup and Resin of Tolu, Tincture of Cinnamon," etc., are also promised.

Mr. William Robert Grove, Q.C., F.R.S., has been appointed to the Judgeship vacated by the removal of Mr. Justice Collier to the Judicial Committee of the Privy Council. In addition to eminence as a barrister, Mr. Grove has a considerable scientific reputation. From 1841 to 1847 he was Professor of Experimental Philosophy at the London Institution, and he has long been an active member of the Council of the Royal Society. Among many other contributions to scientific literature may be mentioned his famous essay on "The Correlation of Physical Forces," published in 1846 and in subsequent editions. In 1847 he received the medal of the Royal Society for his Bakerian Lecture on "Voltaic Ignition and on the Decomposition of Water into its Constituent Gases by Heat." In 1866 Mr. Grove was President of the British Association at its meeting at Nottingham. He has also devoted considerable attention to the operation of the Patent Laws, and was a member of the Royal Commission appointed to report upon them.

From these antecedents, and the scientific character of Mr. Grove's mind, we may expect that the interests of abstract science, and its applications, will receive, through the influence Mr. Grove will now acquire, official recognition and promotion of the kind that is so much needed, and which can only be rendered by those cognizant of the details of scientific matters.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH, EDINBURGH.

The First Meeting for the present session of the North British Branch of the Society was held in Craigie Hall, 5, St. Andrew Square, on the evening of Friday, 24th November, at 8.30; Mr. H. C. Baildon, President, in the chair. There was a good attendance; in addition to those connected with the Society resident in Edinburgh, there were present Messrs. Frazer, Kinninmont and Davison from Glasgow.

The President addressed the meeting as follows:—

Gentlemen,—Having been placed by you for the second time in the honourable position of President of the North British Branch of the Pharmaceutical Society of Great Britain, at the commencement of the session I would ask your indulgence whilst I endeavour as briefly as possible to recapitulate events of great importance that have taken place since our Annual Meeting, and which will, I doubt not, exercise a very beneficial influence on this Branch of the Society, and will afford advantages not hitherto enjoyed to the rising generation of pharmacists in Scotland.

It is well known that the Council had for years felt deeply the inadequate resources at the command of the North British Branch; although it had a name, it had no permanent "local habitation," no sufficient library of reference, and but a very imperfect museum; and of these deficiencies we were made still more painfully conscious when, whilst attending the Pharmaceutical Conference, our esteemed friend Mr. Henry Deane, a fellow-worker with Jacob Bell in founding the Pharmaceutical Society, at his own request, accompanied our Honorary Secretary to our rooms in Princes Street and saw the poverty of our resources. Having the honour and interest of the Society deeply at heart, Mr. Deane at once expressed his intention, at the earliest opportunity, to bring the subject fully before the London Council. This he did, in a very able letter, which I hope all of you have seen in the 71st number of the Pharmaceutical Journal, and which may be said to have exhausted the subject, suggesting that the Council should provide funds, 1st, for the rent of a suite of rooms, to be occupied exclusively by the Society, and not as at present, with two back rooms, available only for one night in the week; 2ndly, that our library should be largely added to and amply supplied with all needful works on chemistry, pharmacy and botany; and, 3rdly, that we should have a museum worthy of the name, containing an ample supply of specimens for our examinations.

I quote the conclusion of Mr. Deane's letter. He says, "As an old examiner and as an old member of Council, having taken deep interest in the welfare of the Society from its foundation, I venture to place this subject before the Council, believing it to be one of the greatest importance, about which no time should be lost and no reasonable expense be spared. It is not a question of money, nor the numbers passing their examinations here or there, but it is one of necessity, affecting our character for consistency and good sense and of justice to those young men who have to appear before the examiners, whether in London or in Edinburgh."

When this letter came before the London Council, it was very properly referred to a select committee to report upon, of which our Honorary Secretary and Mr. D. Frazer, of Glasgow, were members. As it was believed that a good deal of misunderstanding existed in the minds of some of the gentlemen composing this committee as to the origin and position of the North British Branch of the Pharmaceutical Society, I,—as being one of the three pharmacists in Edinburgh who met Mr. Jacob Bell in 1851, and since the death of Mr. John Macfarlan and Mr. Duncan, the only survivor,—was requested by the Council in Edinburgh to accompany Mr. John Mackay and Mr. Frazer to London, in order that I might give evidence before the Committee as to what took place prior to our agreeing to go to Parliament for a joint Act. At a private meeting in my house Mr. Duncan, Mr. Macfarlan and myself were unanimously of opinion that we were entitled to be recognized as a distinct branch of the Society in Scotland; that we ought to have an examining board, endowed with the same powers as the examining board in London, and that we must be recognized as such under the Act of Parliament then contemplated. Mr. Jacob Bell—looking upon it as of great importance that this union should be effected for one common object, namely, the advancement of pharmacy in Great Britain—considered our views reasonable and proper, and undertook to recommend them to the London Council; and our members of Parliament, in accordance with our instructions, had the 12th clause inserted, with the consent of the London Council, in the Act of 1851, which fully recognized our standing and powers.

Those who possess the 1st series of the PHARMACEUTICAL JOURNAL will find the full particulars of this arrangement in Vol. XI. pp. 49 and 63, and I am sure it will interest them if they refer to these pages. My best thanks are due to the Committee for the kindness and courtesy shown in permitting me to read a paper going pretty fully into the history of our Branch Society from its origin to the present time; and the result of the deliberations of the Committee was the following resolution:—"It is the opinion of this Committee that it is the duty of the Pharmaceutical Society of Great Britain to provide better rooms in Edinburgh for carrying on, in a satisfactory way, the examinations and for the general use of the Society in Scotland; also to augment the library and museum there. The Council further think that a paid officer should be appointed to perform secretarial and other duties for the Society under the direction of the Honorary Secretary." At the meeting of the London Council on the 1st of November this report was brought up, when Mr. Deane's letter was read, and the following resolution, being a conjoined motion by Mr. Hills and Mr. Sandford, was unanimously carried, "That the recommendations of the Special Committee on Mr. Deane's letter on the North British Branch of the Pharmaceutical Society in Scotland be adopted, and that the President and Vice-President be requested to put themselves in communication with the Council of the North British Branch, to ascertain what fresh arrangements are required and at what cost they could be carried out."

I congratulate the members on the entire success which has attended our efforts in connection with Mr. Deane's letter, and I trust that the increased facilities for successful study which will in a few months be available to our students will be taken advantage of to their fullest extent. To the young students in pharmacy I would say, if resident in Edinburgh, either temporarily or permanently, you will soon possess great advantages. With suitable rooms, open every day, an excellent library of reference, and an ample museum, taken in conjunction with the favourable arrangements made for you by our Honorary Secretary for your instruction in botany and chemistry,—and we trust soon to be able to add also in materia medica,—if you do not avail yourselves of your favoured position you will have cause for self-reproach and unavailing regret in after years. I will not believe that this will be so, but, on the contrary, that you will use the present season of youth to enable you to fill an honourable place in your profession, whilst, at the same time, you will have taken the surest road to success in life. Many years ago I recollect seeing in a solicitor's office in this city the following words, framed and placed conspicuously over the mantelpiece, "Lost between sunrise and sunset two golden hours, each set with sixty diamond minutes. No reward is offered, for they are gone for ever." This may be said of every wasted hour of life. I would say to you, in the language of our great dramatist,—

"To thine own self be true,
And it must follow, as the night the day,
Thou canst not then be false to any man."

And again,—

"Take the instant way,
For honour travels in a strait so narrow
Where one but goes abreast: keep thou the path,
For emulation hath a thousand sons
That one by one pursue: if you give way,
Or hedge aside from the direct forthright,
Like to an enter'd tide, they all rush by,
And leave you hindmost."

Industry, with average abilities, will arrive at the goal before genius without it. Let each of you then recollect that, to some extent, you cannot tell to how great, the continued success of the Pharmaceutical Society depends upon you. You possess advantages for the successful prosecution of the science of which the last generation knew absolutely nothing; but how zealously the founders of our Society have worked for you need not be told, nor how deep a debt of gratitude you owe to our honoured founder, Jacob Bell. Carry on, then, the good work, which has changed a trade into a profession, and I doubt not you will live to see the pharmacists of Great Britain equal to, if not in advance of, the pharmacists of any other nation. The North British Branch has been peculiarly favoured in obtaining the valuable assistance of professors and others of the highest standing, who have contributed scientific papers of great interest at our evening meetings. Amongst others, I may mention Sir Robert Christison, Bart., Professors Balfour, D. Maclagan, Crum-Brown, the late Dr. George Wilson, Professor Archer, Dr. Stevenson Macadam, Dr. Angus Macdonald, and the late Dr. Scoresby Jackson, and I trust we may be equally fortunate in the future; and I venture to hope that masters, assistants and apprentices will consider it both a duty and a privilege to be present on these occasions. The attendance has not always been what the Council would like to see; and nothing will afford me more pleasure as your President, than that it should be good during my year of office.

I cannot close this address without reminding you of the very pleasant and instructive meeting in this city, in August, of the Pharmaceutical Conference, which was declared by one of its founders to be the most successful that has yet taken place. It was a very great pleasure to others and to myself to be privileged to enjoy the society of the very *élite* of our profession, who were members of the Conference.

Very able addresses have recently been given by two much-esteemed members of the Pharmaceutical Society, the one by our Honorary Secretary, at the opening of the London session, and the other by Mr. Stanford, at the commencement of the Glasgow pharmaceutical year. Both addresses were well worthy of careful study by all pharmaceutical students, and are replete with valuable information and advice.

Mr. Mackay and myself, as office-bearers of the North British Branch, were much pleased to receive a very kind invitation from our friends in Glasgow to be present at the opening of the session, and which we had great pleasure in accepting. The cordial welcome and hospitable reception given to us were most gratifying, manifesting the kind feeling entertained towards the Council of the North British Branch by our friends in the West.

At the close of the address, Mr. MACKAY moved a vote of thanks to Mr. Baildon, not only for the excellent remarks which he had just made, but also because he had, for the second time, taken the office of President. One of the earliest members of the Pharmaceutical Society, he had ever been one of its warmest and earnest supporters. On a recent occasion Mr. Baildon had proved of essential service in placing before the Special Committee in London certain evidence in regard to the position of the Society in Scotland, and thereby earned the thanks of the members and all connected with the Society north of the Tweed.

This was seconded by Mr. Kinninmont, of Glasgow, who referred to the time and labour spent by Mr. Baildon and others in Edinburgh in connection with the affairs of the North British Branch, and expressed satisfaction that the Board in Scotland was about to be placed in a proper position.

After a few remarks from Mr. Kemp, of Portobello, in support of the motion, it was carried unanimously and by acclamation.

A paper was then read by Mr. James Mackenzie, on "Pharmacy in Edinburgh in the Olden Time," which is printed at p. 444.

At the close of the paper, the President proposed a vote of thanks to Mr. Mackenzie for his interesting paper, which was seconded by Mr. Aitken, and carried with applause.

The donations mentioned in the following list were placed on the table, and thanks voted to the donors:—

Specimens added to the Museum since April, 1871.—Lactucarium from *Lactuca virosa*, grown and prepared at Edinburgh by the donor, Mr. Thomas Fairgrieve,—Twenty-four specimens of Thallium and its Salts: presented by Messrs. Hopkin and Williams, London,—Zanzibar Aloes, Natal Aloes: presented by Mr. D. Hanbury, London,—Five Poison Bottles of green glass: presented by Messrs. Frazer and Green, Glasgow,—Square Poison Bottle, with india-rubber stopper fastener: presented by Mr. G. W. Sandford, London,—Sassafras Nuts, the fruit of *Nectandra cymbarum*,—Liq. Calumbæ, *Jateorrhiza palmata*, Ceylon; Rad. Calumbæ ver., ditto; Rad. Taraxaci Siccat., dried and sliced roots of *Taraxacum Dens-leonis;* Rad. Scammonii, *Convolvulus Scammonia;* Fol. *Sarracenia purpurea;* Red Gum of *Eucalyptus rostrata*, Australia; Gum Resin Sarcocolla (*Penæaceæ*); Olibanum, Gum Resin of species of *Boswellia;* Juniper Gum or Sandarach, resin of *Callitris quadrivalvis;* Gum Succini, Amber; Resina Tolutani, residue after making syrup; Ext. Aloes Socot. Aquos.; Socotrine Aloes, residue after making extract: presented by A. F. Haselden, President Pharmaceutical Society.

The Secretary reminded the meeting that, in accordance with the resolution of the London Council, it was most desirable that a suite of rooms should be obtained with as little delay as possible, in which to carry on the examinations and the general business of the Society; and, as such accommodation was not easily obtained, the Council would be glad to have their attention drawn to any suitable apartments, and he would therefore willingly receive any notice in connection with this subject. He also intimated that two copies of Roscoe's 'Chemistry,' just published, and also the new edition of Wilson's 'Chemistry,' by Madan, had just been added to the library.

Provincial Transactions.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION, 1871-72.

The Fourth Session of this Society was inaugurated on the 3rd of November; the President, Mr. J. H. Atherton, F.C.S., in the chair.

The preliminary business, consisting of the election of members, announcements of donations to the Society, etc., having been disposed of,—

The President delivered the introductory address; dwelling on the importance of the work of provincial associations, and urging upon all the necessity of supporting them, the members, by their subscriptions and attendance at the meetings; the associates by their attendance at the lectures, and by their increased attention to business. He then reviewed the work of the past session; dwelling particularly on those questions in pharmaceutical politics which have engaged the attention of the trade during the past twelve months, congratulating the members on the unanimity and heartiness which had characterized all their discussions. The question of "aid to provincial associations" was thoroughly discussed; statistics given to show the necessity of the establishment of some principle of assistance from the Pharmaceutical Society, on a broad and comprehensive basis. He (the President) argued that certain centres of education should be established, with an area of about twenty miles, so that not only the young men in the large towns, but those in smaller towns and villages might have means of education within their reach and at a reasonable price. The same necessity existed for that education in all classes, and yet how widely diverse were the conditions! He thought that the assistance required would only be of a temporary nature, but it should be generously given. The special need of cheap instruction would not be required in a few years; but he (the President) held that, until five years had elapsed from the passing of the Pharmacy Act, they were bound, in the provinces, to give the best instruction they could for the least money; after that time, existing interests having been considered, proper fees could be charged, and then the provincial centres would be self-supporting. Assistance could not be better bestowed at the present time, than by the proper establishment of these centres,—fitting up rooms for library, museum and classes, and, in some cases, by grants towards lectures, for a year or two, where there was a difficulty in engaging suitable men out of the present funds of local societies. He thought that the generous efforts made by provincial men in the cause of education should not only have the sympathy, but the support of the Pharmaceutical Council, and that instead of throwing cold water on such efforts (and he was sorry to say there was an inclination to do so, by persons knowing little of the requirements of young men throughout the country), every encouragement should be given; their difficulties, educationally, increased in inverse ratio to the size of the town. It was the smaller places where the greatest amount of encouragement was needed, and where the greatest amount of help should be given.

The President then alluded to the apathy existing in many places amongst the students with respect to their attendance at the classes provided for them, and made an earnest appeal to those present to realize their position, and the necessity of getting what education they could while they could. He then dwelt at some length on the relations which do now exist, and which ought to exist, between a master and his apprentice in respect to education; and drew a vivid picture of the different position an apprentice now occupied to what he did some twenty or thirty years ago.

Reference was made to the unsatisfactory nature of the apprenticeship system. The President stated that he hoped and believed that in a little time a more satisfactory condition of things would be established. In conclusion, he announced the arrangements which had been made for the coming session, and expressed a hope that members and associates would unite with the Council in promoting the objects the Society had in view; and that by such unity they might attain strength and endurance to carry out the work successfully.

At the conclusion a cordial vote of thanks was accorded to Mr. Atherton for his able and practical address.

Papers have been promised for the monthly meetings of the Society by the President, Mr. Rayner, Mr. W. P. Williams and Mr. Mayfield.

The Committee beg to announce that arrangements have been made for the delivery of two courses of lectures, in connection with the School of Pharmacy, at the rooms of the Society, Britannia Chambers, Pelham Street, by Dr. Soutar. Inorganic Chemistry, every Tuesday evening at 8.45, commencing Tuesday, October

31st. Structural and Physiological Botany, every Thursday evening, at 8.45, commencing Thursday, November 2nd. Nominal fee to each course, *5s.* The introductory lecture in each course will be free to all connected with the trade. The Council particularly request that all young men, who can conveniently attend, will do so, whether connected with the Society or not.

LEEDS CHEMISTS' ASSOCIATION.

The Members and Associates, with several chemists and druggists, numbering nearly ninety persons, met at the Trevelyan Hotel, Boar Lane, Leeds, on Wednesday, Nov. 22nd, 1871, at eight o'clock; the chair was taken by the President, Mr. E. Brown, who delivered the following address:—

Gentlemen,—The advantages of association have been recognized amongst men from the earliest periods. All social and political organizations depend on the impression that, by mutual concession and co-operation, the interests of all so sharing are promoted. Monarchies, republics and empires are but the development of association on a national scale. Let there be first the sense of profit by union, and then will the system, whether crude or complex, to achieve the objects for which the union is designed, spontaneously follow. The associations for the useful direction of energy and enterprise, of capital and skill, of benevolent and philanthropic effort, with their immensely varied objects, that have of late years been formed with such marvellous rapidity, and many with such surprising results, have been for the most part induced by the increase of population on areas long occupied, or by migration to lands before almost unpeopled, and the opening of regions previously unknown. The circumstances calling into being these associations we cannot sever ourselves from,—circumstances that at once demand and promote degrees of mental activity such as probably have never had a parallel.

We live in an age when even that most rude and destructive of arts, the art of war, requires for proficiency in it much patient and scientific study. Does it not behove us, then, engaged as we are in a peaceful and beneficent occupation, to avail ourselves of the aids and advantages secured by mutual association? There are many aspects other than that whence I have ventured to approach our sphere of thought that might convey impressions of the value of union, but, tempting as they are, we have neither the time, nor is this the occasion, to review them. It may be well, however, at this social meeting, before we pass on to subjects immediately concerning us as pharmacists, to notice a few of those inducements to union or association for the promotion of our social and intellectual advancement that have special claim on our regard. The various associations for objects almost without number that exist demonstrate, if demonstration were required, that the experiment of association is conclusively in their favour. Associations and companies often fail of their object, and so of continuance, either because attempting too much, or of being composed of inharmonious elements. It is to be hoped that our friendly union is not endangered by these sources of non-success. The slight claims on our time, our money and our patience are surely counterbalanced by the advantages of our formation into a society. We do not incur responsibilities that can in any degree make union irksome; while there are advantages in association that cannot be had without it. We do not mine to sink our capital, nor speculate in steamy and gaseous evaporations to give it wings. We do not lay rails or make roads on which our means may run away, nor embark to wreck our resources in mid ocean. We do not bind our several interests so closely that dissolution would be a happy release, nor yet is our affinity so insensible that disintegration should be a natural consequence. To harbour the notion that connection with our association lays a man more or less under obligation to reveal anything that might prejudice his personal interest, so far as that interest is not also common to all, is a delusion that incurs more loss to any one who may entertain it than it can possibly to those who do not.

The whole history of pharmaceutical associations, whether in London or the provinces, goes to establish the fact, that those whose position makes them more independent than others of such union are the most ready to communicate what promotes the welfare of their fellow-members. And if there is one lesson more than another that friendly intercourse with colleagues in our art teaches, it is that the aids and the hindrances, the perplexities and the encouragements, falling to the lot of each one are much the same as those that affect all. Our several circumstances, as our separate formulæ, are left intact by our union; but what contributes to the good of all is by it secured alike for each. The very recognition of mutual interests is hopeful and healthful to us in the conduct of business; a fact the more we appreciate, the less we shall have to suffer. The long and anxious hours we have to give to our occupation, while in some respects hindrances, should be in others inducements to our being associated. Our union may be one of the best steps towards lessening the time and lightening the care of our daily round of duty. To be "out of" fashion in some things might be a virtue, but not to be in fashion in the matter of our association, society tending with events as they do, would be a weakness and a loss. We have not so far achieved by our union results to exult in; but we have results quite sufficient to encourage us to persevere. Since our earliest meetings at 13, Briggate, our progressive steps have been steady if not swift, and while our position now is but a modest vantage to have been attained by the engagements of a succession of years, we can from this position look forward with hope that our association, with increased efficiency, will promote the objects for which it was formed. The incidents and the apparatus of our local society are not without interest. That so many of us have formed friendly acquaintance, and so solved down the trade jealousy that is so much the child of ignorance, is surely cause for satisfaction. We have learnt something of each other's weaknesses, and with this knowledge composed ourselves by deliverance from the dread of mastery, and we have seen something of each other's virtues, and so learned to respect those who, with weapons like our own, are daily fighting the battle of life. This acquaintance, too, must infuse into the competition, unavoidable by the proximity of our places of business to each other, more of honour than without it would prevail, and the public also partake of the benefit thus derived from an improved tone in our business transactions. Our winter evening meetings are times of refreshing mental stimulus, whether to those who lead or those who follow the train of thought directed to the subjects that in those meetings come before us; and the organization of our local society, simple as it is, enabled us to take a practical share in stemming the tide of vexatious parliamentary interference in our shop arrangements that threatened the chemists of this land last session; and, if need be, our association, not as an object, but as an incident, of its existence, would serve a like end again; and here it may be remarked that the chief aim of our association, as is that of the Pharmaceutical Society, however some of its members may have overlooked the fact, is to bring about such a state of things in our body as to render government interference in the conduct of our pharmacies quite unnecessary.

It is at once our interest and desire to accord with the action of the Pharmaceutical Society, most heartily and earnestly; but when some members of that Society are led to esteem certain fetters as decorations incumbent on all practising the art of pharmacy, it is for us, with respect and decision, to affirm our purpose to maintain, if possible, undecorated freedom. The standard of professional education required by the Pharmacy Act comprehends the best regulations for the storage and dispensing of poisons, while the time, study and cash involved in attaining that standard, along with all trade considerations to precautions against accident, are the best guarantees that any open suggestions coming from the Council of the Pharmaceutical Society as safeguards at once to chemists and the public will be welcomed and adopted where requisite and applicable; and before we leave what may be termed the incidents of our association, may be mentioned the facts that our associates are privileged to attend at members' fees the lectures on chemistry given at the Mechanics' Institution and at the Young Men's Christian Association, and, lastly, the handsome donation of £10 from the Pharmaceutical Society for the purchase of books now added to our library.

The apparatus of our association may be expressed in a few words:—Cabinet of materia-medica specimens, library, diagrams and maps; the occasional courses of lectures given, the classes for instruction in Latin held, the room we rent for these uses, and may be added the monthly meetings. It would have been cheering had we been enabled to report that these facilities for improvement were more largely used than they have been, specially by the young men for whom they are chiefly intended; at the same time, these advantages have not been without fruit, in aiding several to fit themselves for passing the degrees of ordeal required by the Pharmaceutical Society. It may not be out of place here to remind those who seek instruction, and would receive from our association what it is capable of yielding, that our classes can consist only of those who attend; that the interest of teacher or lecturer may be raised or depressed by the number and the application of those who form his audience. With the admirable chemical courses accessible to our students, it would be a doubtful gratuity on our part to attempt the establishment of lectures on chemistry; but could we secure, as we should do, a sufficient number of earnest learners to form a good class for the study of materia medica and botany, each one composing such a class would be a benefactor to his companions by contributing his share to inducements to the maintenance of the class he attended. Our association affords facilities for the establishment of some such course, and all who are interested in the success of the association would be gratified by seeing that the gifts and their care designed to make our society a source of good to its younger members, have in this important particular secured practical results.

It has been pronounced in various quarters that now that the Pharmaceutical Society has, in consequence of the Pharmacy Act, become more an examining than an educational body, its educational functions will soon expire. While I am not prepared to endorse that opinion, it cannot but be evident to us all that the Pharmaceutical Council cannot undertake the education of the large number who have to pass the scrutiny of its examiners, and consequently that pharmaceutical education and the various appliances that promote it, must, for the most part, be conducted in the provincial centres, accessible to those aspiring to be the pharmacists of our land.

And now I may be permitted the expression of a few thoughts bearing on the examinations—a subject that concerns us all, whether instructors or instructed; and because so much has been said, and said so well on this topic, I shall occupy but little of your time with it. It may be said that the enlightenment of some, and the ignorance of others, who favour us with their custom, are reasons why we should be equal to the position we assume, and the duties we undertake. Society, whether by its intelligence or its confidence, requires in us the ability to acquit ourselves of the responsibilities of the place we occupy in it; and on this hangs the claim for evidence of proficiency in the art we practise.

We live in times when value of all sorts is being weighed, measured and sifted, and these are the conditions, and not from any ambition on the part of the Pharmaceutical Society, or whim of the Parliament, that brought into being the inevitable Pharmacy Act. We cannot sever ourselves from the circumstance; nor would we. It lays on us obligations, but it brings to us hope. With the demand comes the recompense, and with the test the pledge that merit shall not go unrecognized. Your minds may for the moment revert to the prevalence of shams and delusions in our day—shams in science and in art, in commerce and religion, and indeed in every region of thought and practice that sham can invade; but what do these intrusions of the false on the precincts of the true imply, other than that real worth has a place in the esteem of men? and hence that the counterfeit borrows credit only from its likeness to the standard coin. Gems of "paste" and gold-"washed" jewellery find acceptance, inasmuch as they signify that there are things of more value than they are. Influences similar to those that induced the Pharmacy Act have developed the more extensive measure of State education; so that it is well for us, even for our own sakes, to be informed by appointed examiners of our sufficiency or insufficiency to respond to the expectations of an educated public; not that it is probable that the instruction given in our national schools will lift many above the ordinary mental status of those who practise pharmacy, but the advanced education given to the people will dispose and enable them to look for a corresponding advance in our attainments.

From these observations it will be manifest that the institution of examinations in pharmacy, as in anything else, is not to ascertain whether the candidates can just endure the appointed ordeal, but as data whereon to assure the public of their competence to meet the expectations they would raise in the minds of others by the offices they proffer to render to society at large.

The details of the examinations and the numerous aids to preparation for them, have never been more ably discussed than in addresses that have recently appeared in the pharmaceutical press,—addresses that I would commend to the studious perusal of our associates rather than occupy your time by attempting to reiterate their contents. Having noted the source and the reasonableness of the examinations, permit me to say a word or two on the motives to readiness for them,—they are but appeals to the honour of those who would approve themselves to their countrymen. We ask for respect, support and confidence; and we do not pretend to return for these full value in the wares we vend. The balance to material is to be given in the form of *skill*, and, by examinations, we prove we have secured that article, and so in fairness can expect remuneration for it. It is, then, for us but to demonstrate by our whole deportment that we supplement our goods with our qualifications. Fit yourselves for the place you aim at in society, and that will comprehend fitness for the examinations.

Before closing, I now venture a few suggestions to our students, affecting not only the examinations, but your position and progress. It is well to remember, plain as the fact is, that our shops are neither schools nor colleges. We must learn trade as well as science. From practice we have to filter theory, and our province lies in art applied. These thoughts often present may sustain our aspirations while they suppress discontent.

Do not weary of the routine of your daily occupation; repetition is but the confirmation of what we learn. It takes about two years to convert the recruit into an efficient soldier. The novice might during the first week he wore regimentals understand what it was to march and to halt, to load and to fire, to fall into line and to form solid squares and all the etcetera of ordinary martial drill, and, because he knew so much, conceit himself an able soldier; overlooking the most important part of his training,—the education of his limbs to prompt and easy obedience to command. *Our* limbs, too, require education; we need line upon line, and personal experience in the old proverb that practice makes perfect. We were not born chemists and druggists; we become such by training. The young child is prompted to eat by appetite for food, and to walk from desire to lay hold on what is not within its reach; yet to perform these acts respectably, it has to repeat them countless times. The child has to discover by practice the uses of association in its body. It has to accustom each tendon and muscle to respond in harmony with every other to the mandates of its will, before it can with ease and pleasure acquit itself of the simplest exercise. How evident is it, then, that, to arrive at dexterity in our art, we should educate our bodies to the duties we impose on them. The common expression that some men have more sense in their little finger than others have in their whole body, is not inapt, and illustrates what I wish to impress. To this end I would say, let the eye accompany the hand. He who leaves his hand without the guidance of his eye consigns himself to work in perpetual twilight and cancels his title to success. Proficiency in manipulation once secured, labour becomes a pleasure, and occupation rest.

And now, to turn from physical training to mental culture, I have just two thoughts to set before you,—patience and directness; the one says, hold on and wait; the other says, do not wander. To achieve success nothing can compensate for work; not the best opportunities nor the brightest genius. Ability is mainly the faculty to endure. He who is accustomed to patient and steady application is the man of ability; is the man who, with an object once clearly before him, will persevere until he grasps it. It is to be regretted that power of mental endurance is not more generally trained than it is; so much is "ready done" now in our day-schools to save brain-work, that most young men have to learn what mental application means when they should be availing themselves of its practical advantages. There is no faculty of the mind more capable of education, on the one hand, and more dependent on education on the other, than the faculty of sustaining effort. What gymnastics can do for your limbs, this training can do for your wits. Avoid desultoriness; you can scarcely meet a greater foe. The very diversity of our occupations almost tempts to this weakness; but, on the other hand, it affords sufficient variety to dispose you to directness in application to study. Do not use many books; you have not time for them, and they will only divide your thoughts,—one thing at a time, and that one thing do well. You are engaged in a trade or business, as well as giving yourself to study, so digest a few well-chosen books, that they will put you further on; and do not lose time over every bit of "printed matter" that falls in your way; you might as well set yourself to talk with every person you meet. We cannot each excel in every department; it would not be natural for us to be all alike. Let those who have special aptitudes make these the recreation of their study, and so save strength for those subjects that might otherwise be their victors. Thus cherish patience and directness in application to work and to study, and there will be left no place for doubt; true ability will be yours. So nature ever prompts us to industry and economy; it knows neither slumber nor waste. The life of organisms and affinities is ever vigilant towards opportunity for construction; cellular and crystalline forms set before us alike lessons of activity and appropriation in the materials we handle every day.

In closing these remarks allow me, with all deference and consideration, to add, that as a most important collateral to success,—Beware of and shun any vice as a blight that would destroy all good and noble aspiration, and would sow in your heart the poison seeds of disregard for what is pure and true.

As much as crystals, whether of the square prismatic or of the doubly oblique systems, owe their forms to the forces within that attract around their nuclei in directions peculiar to each, so individual character grows into what it becomes by the inner life that actuates it.

We have briefly reviewed association as affecting national life,—as inducing commercial, scientific, and benevolent organizations. We have noted some of the incentives to association, such as the migratory tendencies of our day, that these and other enterprises affect us. We have observed what association might be expected to do for us, what it is doing, and how it may do more; how students unitedly seeking knowledge for themselves confer advantages on their companions. We have noticed the importance of provincial arrangements for pharmaceutical education. We have seen some of the causes for the establishment of examinations, their reasonableness and consequent motives to preparation for them; the mental qualities and bodily training that our business requires, with a few hints on the education of the limbs, the head, the heart.

Surrounded as we are by energies effecting important changes in the condition and expectations of men, it is for us, associated though we may be, to bear in mind that each one, consciously or unconsciously, receives of and gives something to the character that the age wears. So, like every particle of the material world on which falls the light of heaven, returns the ray suited to its capacity, contributes its share to the whole landscape,—may we with like truth respond to the influences that can best enable us to fulfil the object of our being.

Mr. Smeeton then read a paper on "Early Closing and Prices." He alluded to the acknowledged difficulties attending the discussion of these subjects, arising from the varying conditions under which different businesses were conducted. But he expressed a decided opinion that chemists and druggists, both master and man, worked too long and too late, and charged too little for it. He thought that an improvement in the hours of business would only be effected by each individual acting for himself, without too much reference to the conduct of others. With regard to their charges, they had been stationary while all other prices had increased. Twelve months ago a price-book had been compiled. In Leeds it has worked very well. Some have not kept to it, but all have found the good of it. It only wanted the addition, which was hinted at, but never absolutely insisted upon, namely, that every prescription should be marked by the first who dispensed it, and then we should not have any disparity of prices. It was assumed that the tariff price was charged, but he did not think that exceptional prices, whether higher or lower, were always marked. There were several copies left, and it was proposed to supply them at 3*d*. each, which would make them so cheap that they would be worth buying as a useful memorandum, even by apprentices and assistants for their own use.

At the close of the paper, Mr. Smeeton proposed a resolution, "That this meeting desires to express its strong conviction that our hours of business are needlessly long, and urges upon the chemists of Leeds the propriety of closing their shops at an earlier hour."

Mr. Holmes had pleasure in seconding the resolution. He quite agreed with Mr. Smeeton, and had already given practical effect to his thoughts by closing at 7 p.m. with the exception of Saturday, when he closed at 10 p.m.

Mr. Jefferson (Vice-President) hoped every one present would carefully consider the questions introduced in the last paper. It was very desirable that there should be more unanimity; and he thought, had early closing been the rule of to-day, they would probably have had some present this evening who were with them in spirit but not in person. He had pleasure in supporting the resolution.

Mr. Longfield felt the subject of early closing was one of great importance, and if the public knew that chemists' shops were closed earlier, he had little doubt they would remember the want of medicines as well as of groceries.

The resolution was also supported by Messrs. Stead, Abbott and Manfield, and was carried unanimously.

It was resolved that the President (Mr. E. Brown), Messrs. Abbott, Smeeton, Jefferson, Holmes and Simpson, should constitute a committee to give practical effect to the resolution.

Mr. F. Reynolds announced that the committee were enabled to offer four prizes for the best papers written by associates upon the following subjects:—"The Preparations of Iron, officinal and non-officinal;" "Cinchona Bark, the history, varieties, preparations of, and alkaloids obtained from;" "Rhubarb, its history and preparations;" "Magnesia, and its officinal preparations," the two last subjects to be competed for by associates under twenty years of age. No prize would be given unless two or more papers upon each subject were sent in to the Honorary Secretary, Mr. E. Yewdall.

Mr. W. A. Wood was glad to observe the Society so vigorous, and urged upon associates the necessity of making proper use of the present opportunities.

Mr. Geo. Ward proposed a vote of thanks to the chairman, which was seconded by Mr. E. Thompson, and carried unanimously.

Proceedings of Scientific Societies.

SOCIÉTÉ DE PHARMACIE—PARIS.

At the sitting of this society, on the 4th October, under the presidency of M. Lefort, M. Stanislas Martin presented a report of an analytical investigation on the flowers of false ebony (*Cytisus* sp.) which he had undertaken in consequence of some poisoning accidents that had been caused by them. He had been assisted in his researches by MM. Marmié and Husemann, who had obtained cytisine from the husks and seeds of that tree. M. Stanislas Martin has found that alkaloid in the flowers, and has besides extracted from them glucose and an acid that he has named cytisic acid. He presented to the Society specimens of this substance, and of the flower from which it had been extracted.

M. Soubeiran announced that he had just received from M. Van Gorkom specimens of cinchona barks cultivated in Java. The species represented were *C. lancifolia*, *officinalis*, *Calisaya* and *Hasskarliana;* of the two latter species there were barks, branches and roots. The culture of cinchona in Java, as shown by a report recently issued by the Dutch Government, was in a prosperous state, and did honour to the intelligent supervision of M. Van Gorkom, who had collected this year 11,000 kilogrammes of well-dried barks. Half of this quantity was retained in Java, for use in pharmacy and for the preparation of quinium, the finest barks alone being exported to Europe.

M. Petit read a communication from M. Hardy, chief of the laboratory of the Pharmacie Centrale, in which it was stated that if kirsch gave a blue coloration with guaiac resin, it showed that, besides hydrocyanic acid, it contained traces of copper. The presence of alcohol was necessary to this reaction. If it did not take place in cherry-laurel water containing copper, it was because of the absence of alcohol; and M. Hardy described a process for detecting small quantities of alcohol in water, that was founded on this principle.

M. Petit referred to the blue colouring matter that he had obtained from eserin (physostigmatin), and claimed that, although a passing coloration had previously been observed by MM. Vée and Duquesnel, he was the first to obtain a definite substance, of intense colouring properties, crystallizable, and giving, in a toxicological point of view, a reaction seldom equalled among the alkaloids. He also described to the Society a process that he employed for the direct preparation of sulphate of eserin, without having recourse to the distillation of etherized liquors.

M. Limousin made some remarks upon the method of administering medicines by means of gelatine, now adopted in Sweden and elsewhere, and expressed a doubt whether it was applicable in all cases; for example, an emetic such as ipecacuanha, where it was necessary that the medicine should come immediately and entirely in contact with the fluids of the stomach.

M. Grassi said that, although the Swedish pharmacists claimed to succeed in dividing the doses with great exactitude, he believed that in practice there would be considerable difference in the quantity of the medicine contained in different squares of gelatine, as it was impossible to obtain sheets of that substance of the same thickness throughout.

SOCIETY OF ARTS.

Dyes and Dye-Stuffs other than Aniline.*

BY DR. CRACE-CALVERT, F.R.S.

Lecture II.

Red Colouring Substances (continued).—Munject; Campechy Peach, Sapan, Cam and Bar Woods; Alkanet Root; Safflower; Cochineal, Lac Dye; Murexide.

(*Continued from page* 437.)

Sandal, Cam, and Bar Woods.—The next class of dye-stuffs which we shall have the pleasure of studying together are derived from several varieties of the genus *Pterocarpus*, which are indigenous to the tropical parts of both the new and the old world. It is principally from the East Indies, Ceylon, Madagascar and the coast of Malabar that santal, sandal, or red sanders wood is imported, whilst cam and bar woods are procured from Sierra Leone.

The colour-giving principle of this class of plants is only developed with age, the young branches not containing any, whilst it is found in large quantities in the trunk. Professor Bolley proved that it is the same colour-giving principle which exists in each variety, and he gave it the name of santaline. MM. Wagermann and Haeffely consider that it has the formula $C_{15}H_{14}O_5$. It is a bright red crystalline powder, insoluble in water, but soluble in alcohol, ether, and acetic acid. The latter solvent yields the colouring matter to albumen, which is an important fact, and may one day be rendered practically useful. Santaline is freely soluble in alkalies, giving a violet-red solution, from which acids precipitate the colouring matter.

Sandal-wood is chiefly used on the Continent, where it is employed to give a bottom† to cloth which is to be afterwards dyed with indigo. By this process a very fine blue is produced, having a purple hue by reflected light.

Cam-wood, and especially bar-wood, is chiefly used in England for producing on cotton yarns brilliant orange-red colours, known as mock Turkey-reds. They are, however, neither so fast nor so bright as the real Turkey-red produced from madder, and are easily distinguished from it by yielding their colour to a hot soap solution, or to alkalies.

Alkanet.—The root of the *Anchusa tinctoria* contains a beautiful red resinous principle, to which Professor Bolley assigns the formula $C_{35}H_{40}O_8$, which is inso-

* Cantor Lecture, delivered Tuesday, Feb. 14. Reprinted from the *Journal of the Society of Arts.*

† This term is used in dyeing, to denote that a colour is applied to a fabric with a view of giving a peculiar hue to a dye which is applied after it.

luble in water, but soluble in alcohol, ether, and bisulphuret of carbon. To all these solvents it communicates a fine purple colour, which becomes blue on the addition of an alkali. It is not at the present day employed as a dyestuff, its chief uses being in pharmacy to colour medicines; in perfumery, to colour oils and greases; and in domestic life to give a tint to the lime-wash used for the walls of private dwellings.

Safflower.—Although this dye-stuff has lost much of its value since the discovery of the aniline colours, it is still extensively used in Lancashire for the production of peculiar shades of pinks for the eastern markets. It is also used for dyeing red tape, and I know no more striking instance of red tapeism than the love which is shown for this particular dye by the users of this article. Much cheaper pinks can be produced from aniline, and, notwithstanding that many times the attempt has been made to introduce them, it has in every instance failed, because the exact shade has not been attained.

Safflower is the bloom of a peculiar thistle called *Carthamus tinctorius*, which is cultivated in France, Egypt, Spain, Italy and India. In France and Spain, the small flowers composing the heads of the thistle are picked off and dried in the shade, whilst in Egypt and India they are squeezed, washed with cold water to remove useless materials, slightly pressed into lumps, and dried in the shade; the latter have about double the value of the former. The safflower so prepared only contains three to six parts per thousand of the colour-giving principle.

This principle has received the name of carthamic acid, and has the formula $C_{14}H_{16}O_{14}$. A solution of this acid, when dried on a polished white surface, leaves a varnish, having a beautiful red colour, by transmitted light, whilst it assumes the iridescence of cantharides when seen by reflected light. It is insoluble in water and ether, but soluble in alcohol. This solution becomes yellow on the addition of sulphuric, nitric, or hydrochloric acid. It is also turned yellow or orange by weak alkalies, and the colouring matter in this latter solution undergoes rapid alteration if exposed to the atmosphere. It is owing to the fugitive nature of the colour and its easy modification by acid and ammoniacal vapours, that the delicate pinks produced from safflower have been so successfully replaced by the pink aniline dyes.

To prepare carthamic acid, safflower is introduced into bags and washed, till a yellow colouring matter, which it contains, is removed. It is then mixed with water, to which is added 15 per cent. of the weight of safflower taken of crystallized carbonate of soda. After two hours' maceration, the liquor is run off, and cotton yarn dipped in; then lemon juice or citric acid is added to liberate the carthamic acid, which fixes itself on the yarn. Up to this point, the process is the same as that adopted in dyeing fabrics, but to obtain the acid it is necessary to treat the washed cotton a second time with carbonate of soda, which dissolves out the carthamic acid, leaving a second yellow colouring matter fixed on the cloth. The carthamate of soda thus obtained is decomposed by tartaric acid, and the carthamic acid falls as a brilliant red amorphous powder, which, when mixed with a little water, is sold as safflower extract, and when dry and mixed with ground talc, is employed as *rouge* by ladies.

There is a particular extract extensively used in dyeing, the preparation of which is a secret. Its value depends on the fact that the carthamic acid is rendered soluble in water.

Cochineal, Kermes, Lac-dye, and Murexide.—I shall now call your attention to four colours derived from the animal kingdom, namely, cochineal, kermes, lac-dye, and murexide.

The first three are distinct species of a peculiar tribe of insects called *Coccina*. The females, from which alone the colouring-matter is derived, form a mass nearly destitute of limbs, and remain attached to one spot on the plants infested by them. The males, on the contrary, are very minute and really elegant creatures, furnished with a single pair of filmy wings. The real cochineal is called *Coccus cacti;* kermes, *Coccus illicis;* and lac-dye, *Coccus lacca* or *ficus*. They all contain the same colouring principle. Although the dyes derived from some species of these insects were well known to the ancients, and were much used in Persia and India, the true cochineal has only been known in Europe since the discovery of America by the Spaniards; and since the year 1830 only has it been propagated in the Canary Islands, the island of Teneriffe, Java, and Algiers. The best qualities are still obtained from the republic of Honduras.

The *Coccus cacti* lives on a species of cactus called the *Cactus nopal* or *Opunta coccinilifera*. This plant is indigenous to Mexico, where it grows in the wild state; and from it large quantities of cochineal are collected. It is also extensively cultivated by the native Indians, who often have plantations containing 60,000 plants. The cochineal obtained from the two sources is of different quality; that from the cultivated plant is much superior, and is called *mestique;* that collected from the wild plant is called *sylvestra*.

I will now explain, in a few words, how cochineal is propagated and prepared for market. In the month of May, in the flat lands, and in November in the mountainous districts, the Indians take the stems of the cactus, which they have preserved from a previous crop, and remove from them the young female insects, which are placed on the growing plants, where they grow and multiply with great rapidity. After a period of about three months, the insects are collected into small tin dishes, so formed as to enclose the bottom part of the plant, and by means of a small brush they are swept from each stem successively into it. They are then destroyed, either by being thrown into hot water and afterwards dried in the sun, or in stoves, which gives the black cochineal, called *zacatilla*, or they are placed in a bag and stoved at once, which leaves upon them that peculiar lustrous appearance which characterizes the silver white cochineal, called *blanco*. Although one pound of cochineal contains 70,000 insects, there are millions of pounds imported into Europe every year.

If one of the dried insects be placed in warm water, it swells and takes a hemispheric form, when its structure can be seen. If it is pressed between the fingers, thousands of little red grains are exuded, which, if placed under the microscope, are seen to be minute cochineal insects.

The colouring principle was first isolated in an impure state by Pelletier, who considered it to be an azotized compound. MM. Arppe and Warren de la Rue, however, found that it contained no nitrogen, and that it had the formula $C_{14}H_{14}O_8$. As it had distinctly acid properties, they gave it the name of *carminic acid*. M. Schützenberger proved that carmine is composed of carminic acid and an organic azotized base, called *tyrosine*.

MM. Arppe and Warren de la Rue obtain crystallized carminic acid by the following process. The cochineal is treated with ether, to remove fatty matters, then boiled in water. An acid acetate of lead is added to the solution thus obtained, which precipitates an insoluble carminate. This, after being washed carefully, is decomposed with sulphuric acid, the carminic acid being liberated. The aqueous solution is evaporated to dryness, and the mass treated with alcohol, which, on evaporation and cooling, yields it as a crystalline mass.

As shown by the above process, carminic acid is insoluble in ether, but soluble in water and alcohol. It is dissolved without decomposition by concentrated sulphuric and hydrochloric acids. Carminic acid yields on fabrics, especially on wool, one of the fastest colours known, light and air having no action on it. Chlorine, however, easily destroys it. An aqueous solution of the acid gives the following characteristic reactions. With caustic alkalies, it gives a beautiful crimson-red colour; with oxymuriate of tin, it gives a red precipitate; and with cream of tartar or oxalate of potash, an orange-red precipitate. Alumina removes the whole of the colouring-matter from an aqueous solution. As cochineal is an expensive dye-stuff, it is subject to much fraud and adulteration. One of the most common frauds is practised at Nismes and other places where perfumery is largely prepared. The cochineal in those localities is put into water for a short time, by which a part of its colour is extracted; it is then dried, and either sold as black cochineal, or placed in a sack and shaken with talc or sulphate of lead, and sold as white cochineal. This fraud is easily detected by grinding the cochineal and mixing it with water, when the talc or sulphate of leads falls to the bottom. Good cochineal does not leave above five or six per cent. of ash.

It is often advisable before buying cochineal to determine its tinctorial power. This may be ascertained by two or three methods. In the first, equal weights of the cochineal to be assayed, and of one of known value, are treated with alcohol or a solution of alum. The solutions thus obtained are poured into tubes and placed in a colorimeter. This is an oblong box, which has two apertures at each end and two on the top, in a direct line with the end apertures. The tubes are placed through the openings on the top, and on looking through the end apertures, any difference in intensity of colour between the two liquids can be observed. If a difference is detected, alcohol or water is added to the stronger liquor until there is perfect uniformity of tint. According to the amount of dilution required is the relative value of the cochineals.

A good process was published by the late Dr. Penny, of Glasgow. It consists in exhausting a gramme of cochineal with fifty grammes of potash solution, and this extract is further diluted with 100 grams of water. The solution thus obtained is mixed with a graduated solution of ferricyanide of potassium (one gramme of salt to 200 grams of water) till its colour changes to a dark brown. A solution of bleaching-powder of known strength can also be used for the same purpose. The best method consists in dyeing equal surfaces of flannel in a bath composed as follows:—

For Scarlet Tints.

	Grams.
Water	1250
Cream of Tartar	2
Tin Composition	2
Cochineal	1

For Crimson Tints.

	Grams.
Water	1250
Cream of Tartar	0·75
Alum	1·50
Cochineal	1

The pieces are then washed and dried, and by a comparison of the relative intensity of shade the value of the cochineal is determined.

The chief employment of cochineal is for dyeing wool, but it is also employed in calico printing to produce pinks and reds in steam styles.

It will no doubt be interesting to you to know how to determine whether a pink has been produced from a dyewood, a cochineal, or from madder. All these colours are destroyed by chlorine or bleaching-powder. A boiling soap solution destroys the wood pinks, communicates a crimson hue to the cochineal dye, and brightens the madder colour. Dipped in a rather dilute solution of hydrochloric or sulphuric acid, fabrics dyed with cochineal are not affected, while those dyed with madder or woods assume a yellow tint, which becomes purple when placed in milk of lime. These cloths, however, if subsequently soaped, will yield their colour if dyed with wood, but not if dyed with madder.

Ammoniacal Cochineal.—When one part of ground cochineal is left in contact with three parts of ammonia for several weeks, a chemical action ensues, by which the ammonia loses one equivalent of hydrogen, which unites with an equivalent of oxygen of the carminic acid, giving rise to water and an amide compound, carminamide. Adopting M. Schützenberger's formula for carminic acid, the change may be thus represented:—

$$\underset{\text{Carminic Acid.}}{C_9H_8O_5} + \underset{\text{Ammonia.}}{NH_3} = \underset{\text{Water.}}{H_2O} + \underset{\text{Carminamide.}}{C_9H_9NO_4}.$$

This compound is also used for dyeing, but before employing it for this purpose it is necessary to add 4 per cent. of alumina, in the state of jelly, to the mixture described above. The mass is then slowly evaporated to the consistence of a thick paste. By this means all excess of ammonia is expelled. This preparation is used for dyeing silk, and to produce violet and mauve colours on woollen goods.

Carmine Lakes.—These very beautiful pigments are prepared from a decoction of cochineal, and not from carminic acid, the animal matter which the insect contains, appearing to be necessary to their production. The mode of preparing the finest qualities is kept a secret by the manufacturers; but I will describe two processes, which give very satisfactory results. The first consists in boiling one pound of ground cochineal with two gallons of water, to which has been added one ounce of alum. It is then boiled for three minutes, the liquor is allowed to settle, and, after having been kept for several days, about an ounce of a bright carmine lake is produced. For the alum employed in this process cream of tartar can be substituted. The second process consists in boiling for three hours two pounds of powdered cochineal in thirty gallons of water. To this is added three ounces of pure saltpetre. The liquor is then boiled again and left to settle. The clear liquor is run off, and after two or three weeks yields a fine carmine lake.

As these lakes are expensive, they are often adulterated with starch, kaolin, vermilion, etc. The complete solubility of pure carmine lakes in ammonia affords a ready means of detecting these adulterations.

Kermes.—This colouring matter is also derived from a variety of *Coccina*, which lives on the species of oak called *Quercus coccifera*. The young female animal fixes itself under the epidermis of the leaves or young shoots of the oak, in the early part of spring. As the insect grows, it gradually swells out the epidermis, covering the surface of the leaves or branches with a multitude of excrescences. During this period it deposits its eggs.

In Spain and the south of France, during the month of June, or just before the eggs produced would be hatched, the animals are removed and destroyed by placing them in the steam from heated vinegar.

Although this colouring-matter is seldom used in England, it is extensively employed in the south of France, in Spain, Morocco and Turkey, to dye morocco leather, and to dye woollen cloth with that particular shade which characterizes the cap called "fez," worn by the Asiatics.

If the colour is not so brilliant as that of cochineal, it has the advantage of not being changed by soap or dilute alkalies. It is also employed at Milan, Rome and Florence to colour a very favourite beverage known as alkermes. The colour-giving principle of this insect is identical with that of cochineal, and has been used as a dye in the East from time immemorial.

Gum-lac.—This is another variety of the *Coccina*, which lives especially on the *Ficus*, or fig-tree. They reproduce themselves with such rapidity and in such numbers that they entirely cover the surface of the branches of the trees on which they are deposited. Owing to a resinous fluid which they secrete, they form solid masses, which are often a quarter of an inch thick, all round the branches, and adhere very firmly to them. The natives break off these branches just before the hatching season of the animal, and expose them to the sun to kill the insect. These gum-lac twigs are sold under the name of stick-lac. Those of Siam are considered the best, those of Assam next, and those from Bengal the worst.

There are three kinds of lac in commerce—stick-lac, which has just been described, seed-lac and shell-lac. The resinous concretion is taken from the twigs, coarsely powdered, and triturated with water in a mortar. The greater part of the colouring principle is thus dissolved. The granular portion which remains is dried in the sun, and constitutes seed-lac. Shell-lac is obtained by melting seed-lac and straining whilst hot. It is then dropped upon smooth stems of the banyan tree, and so runs into thin plates, which are known in commerce under the name of shell-lac.

These three lacs have the following composition:—

	Stick-lac.	Seed-lac.	Shell-lac.
Resin	68·0	88·5	90·9
Colouring matter	10·0	2·5	·5
Wax	6·0	4·5	4·0
Gluten	5·5	2·0	2·8
Foreign matters	6·5	..	..
Loss	4·0	2·5	1·8
	100·0	100·0	100·0

The colouring matter of the insect is identical with that of cochineal and kermes, and it has been employed as a scarlet dye-stuff in the East from time immemorial.

Lac-lake and *lac-dye* are preparations imported into this country from India since 1796. They are both prepared by acting on stick-lac by a weak alkaline solution, to which is then added a solution of alum. This produces a precipitate, which, when washed and dried, is ready for use. Although both these lakes are prepared with the same substances, lac-dye is considered much superior in quality. This is due to the greater care bestowed on its preparation. The details of the process are kept secret.

To dye woollen cloths with them, they are dissolved in a weak solution of vitriol, to which is added a little oxymuriate of tin, and the cloth dipped in when the liquid is near the boil. It only requires washing and finishing to be ready for market.

Some years ago, Messrs. E. Brooke and Co., of Manchester, introduced a lac-dye much superior to that imported from India, which they prepare by treating stick-lac with weak ammonia, and adding chloride of tin to this solution, when a fine red precipitate is formed, which, collected, is ready for use.

Murexide or Roman Purple.—Although this colour has now been superseded by those derived from coal-tar, I call your attention to it as an example of the assistance rendered by the progress of chemistry to the art of calico-printing.

In 1776, the illustrious Swedish chemist, Scheele, discovered *uric acid* in human urine. In 1817, Brugnatelli found that nitric acid transformed uric acid into a substance which he called *erythric acid*, but which was afterwards named by Wöhler and Liebig *alloxan*. In 1818, Dr. Prout found that this latter substance gave, when in contact with ammonia, a beautiful purple-red colour, which he named *purpurate of ammonia*—the product known by the name of *murexide* since the researches of Liebig and Wöhler in 1857. These discoveries remained dormant in the field of pure science until the year 1851, when Dr. Saac observed that when alloxan came in contact with the hand it tinged it red. From this he inferred that it might be employed to dye woollen fabrics red, and further experiments showed that if woollen cloth, prepared with a salt of tin, were passed through a solution of alloxan, and then submitted to a gentle heat, a most beautiful and delicate pink colour was obtained.

In 1856, MM. Depouilly, Lauth, Meister, Petersen, and A. Schlumberger, applied it as a dyeing material to silk and wool, and succeeded in producing red and purple colours, by mixing the murexide with corrosive sublimate, acetate of soda and acetic acid.

For printing upon cotton, a mixture of murexide with nitrate of lead or acetate of zinc, properly thickened, was printed on the fabric, which was then allowed to dry for a day or two, when the colour was fixed by passing them through a mixture of corrosive sublimate, acetate of soda and acetic acid.

The uric acid required for the preparation of such large quantities of murexide, was obtained from Peruvian guano. The guano was treated with hydrochloric acid and washed. The insoluble mass was then treated with nitric acid of specific gravity 1·40. When the action of the acid was completed, the mass was treated with warm water to dissolve out the alloxan. It was then carefully evaporated to such a degree that it became solid on cooling. The solid mass had a brown or violet colour.

Parliamentary and Law Proceedings.

PROSECUTION OF A CHEMIST FOR MISREPRESENTATION.

At the Leicester Town Hall, on Monday, 20th November, William Lakin was charged with wrongly representing himself as a doctor of medicine.

Mr. Owston for the prosection, Mr. Fowler for the defence.

Mr. Owston pointed out that under the Medical Act it became necessary that any one practising in medicine should be entered in the Medical Register, and the absence of any name from that Register was sufficient ground for supposing that he was not an enrolled member of that Society, and was not entitled to style himself doctor of medicine, and had contravened the Act. He then described defendant's shop, which, he said, contained all the concomitants of an apothecary's shop, and upon the door-plate was "Dr. Lakin." He also pointed out that defendant had issued a certificate, in which he had signed himself "William Lakin, M.D. (U.S.)."

William Dalrymple, manager of the Leicester Provident Dispensary, who said he laid the information in this case. Defendant resided at 16, New Bond Street. Witness had been in the habit, almost daily up to Nov. 13, of passing his house. He had noticed on a brass plate, at the right-hand side of the door, at 16, New Bond Street, "Dr. Lakin." Had noticed in the window three or four bottles containing coloured liquid, castor oil (the bottles having on them the Latin names), syringes, catheters, pamphlets on medical subjects. Through the door he could see into the shop, and in it were the ordinary fittings of a surgeon's shop. Over the window and door was a board, containing "Dr. Lakin, botanic practitioner."

By Mr. Fowler: As an outside observer it did not strike him as the shop of a chemist and druggist, by the entire absence of scents and other drugs. The books on medicine are not usually exhibited in the shop of an ordinary chemist and druggist. In the ordinary druggist's shop the window was made attractive; defendant's was left careless, as is usual in open surgeries. Open surgeries are not customary in Leicester, but are in London and other large towns. Was not aware that Mr. Lakin was registered as a chemist.

Re-examined: Did not usually find a plate at the entrance of a druggist's shop.

Charles H. Marriott said he was M.D. and F.R.C.S. The title of M.D. was conferred by various universities throughout the world. The only universities in England that could grant that degree were Oxford, Cambridge, London and Edinburgh. The degree of doctor was a very ancient one. He believed it extended as far back as 1384.

Cross-examined: There were many universities out of England that could grant that degree.

Elizabeth Blowers, living at No. 4, Noble's Yard, said she had a child of the name of Arthur Blowers. It died on the 9th of October. It was attended by Mr. Lakin. On the day of its death he gave her a paper partly printed and partly written. She took it to Mr. Warburton. Had several bottles of medicine from Mr. Lakin. Paid 8*d.* for each bottle except one, and that she gave him 1*s.* for. He attended the child that time at her own home. She took the child to his house on the other occasions.

William Hobday said he was deputy-registrar of births and deaths for the east district of Leicester. Wood Street was in that district. Received the certificate produced from Elizabeth Blowers.

Mr. Fowler said Mr. Owston had quoted a number of cases which were said to have a bearing upon the point, but he submitted they clearly disproved, or at any rate rebutted the case his friend had attempted to set up. The question they had to decide upon was this; whether defendant had—according the words of the Act of Parliament, the 40th section—wilfully and falsely pretended to be or take or use the name or title of a doctor of medicine, or any name or description that was required by law for a physician. The question was the false pretence,—had the defendant wilfully and falsely pretended to be what he was not. Assuming everything had been proved, he submitted he should be able to prove there was no false pretence. Admitting, for the sake of argument, that the certificate produced was signed by Mr. Lakin, they must look at the whole description, and they would find it was M.D. (U.S.). He should be able to produce to them a diploma, granted by the College at Pennsylvania. He then called the magistrates' attention to the cases of Ellis *v.* Kelly, and Steel *v.* Hamilton, as being proofs that the defendant was justified in the course he had pursued. Mr. Dalrymple's evidence he criticized as something ridiculous. The complainant, he submitted, had failed to present any false pretence, and concluded by reading a diploma granted to the defendant by the "Eclectic Medical College of Pennsylvania" during the year 1870.

Francis William Crick, of Bedford, "eclectic" practitioner, said he was a member of the College of Pennsylvania. That was a college in the United States, having authority to grant diplomas in medicine. Had not been in Pennsylvania. There was a board of examiners in this country communicating with them. He was not on that board. Had had correspondence with Dr. Buchanan, and knew his handwriting. The handwriting on the diploma produced he knew was the handwriting of Dr. Buchanan. They could be examined by a board of examiners in this country without going over to Pennsylvania. Had been himself examined by the board in this country. The result of the examination was transmitted to Pennsylvania. (Cross-examined:) There must be a personal examination. The preliminary branch of education he went through was general English. He went through his preliminary education at Bedford. The board of examiners sent to them questions by post, and they filled them up at home, and transmitted them to Dr. Payne, of Leeds. They were examined at Leeds in surgery, anatomy and obstetrics. Witness was under the tuition of a competent preceptor for over three years. Did not personally know any preceptor. Never saw the doctors before whom he passed his examination in his life. It was not necessary to be three years under the tuition of a medical preceptor, nor was it necessary for them to go before the medical examiners. He was before the board in Leeds in 1867, but did not know who they were. Could not tell the justices one question they asked him, neither in surgery or botany. Could not tell them what he paid for his diploma, but it was a considerable sum. Was sure it was more than £10. (By the Mayor:) It was something between £10 and £100.

Mr. Owston said defendant had put in a diploma which was a fraud.

The Mayor said the action involved rather an important question, not only for Leicester but for other parts of the country, and the magistrates therefore reserved their decision until Friday week.

SUSPECTED POISONING BY ANTIMONY.

At the adjourned inquest held at Birmingham on Tuesday last, to inquire into the death which it was suspected had been caused by antimony, Dr. Hill made his report of the result of an analysis of the contents of the intestines of another child, which the coroner had ordered to be exhumed (see *ante*, p. 397). Dr. Hill deposed that there was sufficient antimony in the intestines of this child also to cause death, and it was shown that its death was accompanied by symptoms similar to those which marked the decease of the sister. The coroner has ordered the exhumation of another child, and the intestines are to be examined by Dr. Hill. Meanwhile the mother is in the hands of the police. One of two children left out of twelve is said to be dying.

MEETINGS FOR THE ENSUING WEEK.

MONDAY Dec. 4.	*Medical Society*, at 9 P.M.
	Society of Arts, at 8 P.M.—"On the Manufacture and Refining of Sugar." By C. Haughton Gill. (Cantor Lecture.)
	London Institution, at 4 P.M.—"Hearing." By Professor Huxley. (Educational Course.)
WEDNESDAY Dec. 6.	*Pharmaceutical Society of Great Britain*, at 8.30 P.M. Evening Meeting.
	Society of Arts, at 8 P.M. "Sewage as a Fertilizer of the Land, and Land as a Purifier of Sewage." By J. Bailey Denton.
THURSDAY Dec. 7.	*Chemical Society*, at 8 P.M. "On Essential Oils." By Dr. J. H. Gladstone.
	Linnean Society, at 8 P.M.
	Royal Society, at 8.30 P.M.

VACANCIES AND APPOINTMENTS IN CONNECTION WITH PHARMACY.

The Editor will be glad to receive early notice of any vacancies of pharmaceutical offices connected with public institutions, and likewise of appointments that are made,—in order that they may be published regularly in the Journal.

APPOINTMENT.

Edward Parker Wolff, Dispenser to Baron Ferdinand de Rothschild's Evelina Hospital, and Registered Student of the Pharmaceutical Society, has been appointed Head Dispenser to St. Thomas's Hospital.

VACANCY.

There is a vacancy for a Dispenser at St. Thomas's Hospital; Candidates must have passed the Minor examination of the Pharmaceutical Society. Salary, £80 per annum. Hours from 9 A.M. till 6 P.M.

BOOK RECEIVED.

THE POCKET FORMULARY AND SYNOPSIS OF THE BRITISH AND FOREIGN PHARMACOPŒIAS, comprising Standard and Approved Formulæ for the Preparations and Compounds employed in Medical Practice. By HENRY BEASLEY. Ninth Edition. London: J. and A. Churchill. 1872.

The following journals have been received:—The 'British Medical Journal,' Nov. 25; the 'Medical Times and Gazette,' Nov. 25; the 'Lancet,' Nov. 25; the 'Medical Press and Circular,' Nov. 29; 'Nature,' Nov. 25; the 'Chemical News,' Nov. 25; 'English Mechanic,' Nov. 24; 'Gardeners' Chronicle,' Nov. 25; the 'Grocer,' Nov. 25; the 'Journal of the Society of Arts,' Nov. 25; 'American Journal of Pharmacy' for November; the 'Canadian Pharmaceutical Journal' for November; 'Journal de Pharmacie et de Chimie' for October; the 'Chloralum Review' for November; 'Brewers' Guardian' for Nov. 6; 'Midland Free Press,' Nov. 25.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Pharmaceutical Aid for Chicago College.

Sir,—Our pharmaceutical brethren in Chicago have lost by the great fire, their College, with its library, lecture-specimens, apparatus, herbarium and furniture. Worse still, many of its founders, and most of its best supporters in Chicago, in short, six wholesale and forty-six retail druggists have lost their businesses and all their property, and, therefore, the means of raising the College from its ashes. Under these circumstances, they beg for aid from fellow-workers. They do not ask us to send help to themselves; for their railroads and lakes, and their indomitable energy and pluck, are still left to them; moreover, the druggists of New York have sent them £350, San Francisco nearly £200, and so on; but they do ask all interested in pharmacy in Great Britain to aid them in reinstating their College. I am sure they will not appeal in vain.

The accompanying letters show the condition into which pharmacy and the pharmacists of Chicago have been thrown by the great conflagration. In a private letter Professor Ebert tells me that the loss in respect of the College is about £2000. There is a partial insurance, but it is in Chicago offices, and therefore, of little value.

In responding to this appeal, I shall be happy to act with a small committee, representing the wholesale and retail druggists of our cities and provinces. Already the President of the Pharmaceutical Society, Alderman Sir Thomas Dakin, lately the Lord Mayor of London, the President of the Pharmaceutical Conference, and Thomas Hyde Hills, Esq., have consented to act on such a committee. Meanwhile, I shall be glad to receive here, at 17, Bloomsbury Square, London, books and specimens or apparatus for lecture-illustration, with contributions wherewith to purchase the same. Cheques and post-office orders may be drawn in my name; the former being crossed "London and Westminster Bank," and the latter made payable at "High Holborn." I will undertake to forward all parcels, and have good grounds for stating that freightage will be reduced and customs' duties remitted.

The first list of contributors and subscribers will be published next week. Yours faithfully,

John Attfield.

"Chicago College of Pharmacy.

"*To* Professor Attfield,
"*London, England.*

"*Chicago, October* 31*st*, 1871.

"My dear Sir,—The interest you have always shown in our College leads me to lay before you a statement of the loss we have sustained, thinking that in your extensive intercourse with British pharmacists you might be able to secure aid for us in replacing the College in its former position of usefulness.

"We would not make this application but for the fact that nearly all our active members have lost, like the College, all they possessed. In this really lies our weakness, as, otherwise, we could easily build it up again. All our library, cabinets of specimens, herbarium, apparatus and implements for instruction, book-cases, furniture, and many other articles of value, collected by years of effort, with the entire stock of the *Pharmacist*, are gone. The College of late was more prosperous than ever, and its influence was becoming a power for good in the elevation of Western pharmacy. Under such circumstances, we feel that others interested in the promotion of the progress of pharmacy may be induced to assist us in reviving the College, and would ask you to represent us wherever you find those who are interested in our endeavours. We do not lack willing hands nor strong hearts to do the work set before us, and with the assistance and sympathy of our friends, we trust the future of our beloved College may be far better than its past.

"Thanking you for your interest in our welfare, we
"Remain yours respectfully,
"Albert E. Ebert,
"*Corr. Secy. Chicago College of Pharmacy,*
"*Corner of State and* 12*th Streets, Chicago,*
"*U. S. A.*"

The Chicago Catastrophe.

Sir,—So many inquiries have reached me during the past week or two concerning pharmacists in Chicago, and the extent of the losses they have sustained in the late fearful conflagration, that I have thought I might send you the accompanying letter from Professor Ebert, believing that, although not written with any view to publication, it can hardly fail to interest your readers.

The appeal it contains on behalf of the College of Pharmacy can scarcely pass unheeded by English pharmacists. There can be little doubt that our publishers and publishing societies, if rightly approached, would willingly aid in the undertaking; there may be many duplicate or little used pharmaceutical books in the libraries of your readers which would be cheerfully presented to make good the loss; and in other ways your readers will, doubtless, readily contribute.

When in Chicago, in September, I visited the rooms occupied by the College, and found very efficient arrangements for educational purposes, evening meetings, and the like, though necessarily, in a young institution, on a somewhat small scale; too small, I should suppose, for the number of students who appear to have entered at the beginning of the present ill-fated session.

I am, yours very truly,
Henry B. Brady.

Newcastle-on-Tyne, Nov. 18*th*, 1871.

P.S. In the letter appended I have eliminated a few sentences of purely personal character.

"*To* Henry B. Brady, F.L.S.,
"*Newcastle on-Tyne.*

"*Chicago, Nov.* 3*rd*, 1871.

"My dear Friend,—Your most welcome and sympathetic letter has just come to hand, and was opened by our mutual and unfortunate friend Sargent, who is making (like many others of our colleagues whom the "fire fiend" did not spare) my store his headquarters until his (which is being located on the corner of Wabash and 16th Streets) is finished. Mr. Sargent and myself were much pleased to hear from you, and of your safe arrival on the shores of *generous old England*, whom Chicago will hereafter only remember as a distant friend, extending to us the liberal assistance now pouring in at this hour of distress. We all thank her, and shall never forget this friendship of humanity when our troubles are over, and our ship again sails in calm water. I am safe as far as my personal safety and that of my business is concerned, but I may yet become a heavy loser should the insurance companies do no better than they appear to promise at present. The conflagration was fearful, and no pen has yet written an account that has done justice to the ravages of this terrible fire. Our colleagues who suffered (and they number from 40 to 50), like the balance of the populace, saved *really nothing*. All was consumed, there being no time left to attend to anything but personal safety. Among those you met at Mr. Buck's house only two escaped, Mr. Ehrman and myself. Messrs. Buck and Rayner lost both stores; they have again opened on the corner of State and 16th Streets; Mr. Whitfield has opened on the cor. of State and 18th Streets, Mr. Sargent on the cor. of Wabash and 16th, Mr. Parson on the cor. of Wabash and 14th, Bliss and Sharp have removed to their store cor. Wabash and 22nd. The College and its contents were burned the first night. We have *lost all*, with the whole stock of the *Pharmacist*. I have written a letter to our mutual friend Attfield, from whom I had a pleasant and sympathetic letter the day before yesterday, in which I enclose a personal appeal for the Chicago College in the way of contributions of specimens, books, etc. These we cannot purchase even if we had the money, which we do not ask. I know you will plead for our cause, and therefore thank you beforehand. The fire was checked on the corner of Harrison Street, in close vicinity of Ehrman's store. Just imagine for one moment the whole of the south division, from Ehrman's store north, and the whole of the north division as far as we drove that Saturday afternoon in September, *all gone*, excepting one solitary house. Nothing is left of those fine buildings which I was so proud in pointing out to you during our drive and our various rambles while you were here. I have so many friends who were rich and are to-day poor,—nothing left them but their good names and credit (which is something) to start again in life. But many are far advanced in life, and it seems so hard that they again must commence at the foot of the ladder.

Take Mr. —— as an example, one who has struggled bravely, and had just accomplished a long-desired object in getting the whole of the business into his own hands, to be swept away in one night, so that not one cent is left him, but, on the other hand, an embarrassment of about 8000 dollars debt. He was insured for 24,000 dollars, out of which he will realize about 5000 to 6000 dollars. Still he holds out bravely, and is putting up a temporary building on his new location. Bartlett lost nothing, excepting what he had at the College. Your friend, the writer, lost all his apparatus, instruments, books, specimens, and many highly cherished articles which he had been collecting for years, and had taken to the College for use in the just-commenced course of lectures. We had every prospect of a very successful session, having on the opening night some 43 matriculants, and with the expectation of at least a class of 50 students. After the fire, for a week or so, we hoped that we might continue the course, and had made arrangements with the Chicago Medical College for the use of their specimens, apparatus and rooms, but we were doomed to disappointment by the severe illness of Prof. Hambright, which resulted indirectly through the excitement of the fire. He was left very low and prostrated, and his physician ordered him to be removed from the city. This has put a stop to our proceedings for the present, still hoping, however, that, with the aid of our friends, we shall be well prepared to continue next winter. We have had much assistance sent us, 800 dollars from San Francisco, 17,000 dollars from New York city. Still, there is considerable want even of the necessities of life among those who have never been accustomed to asking relief. These are really the greatest sufferers, and it becomes our duty to seek them out, and save them, if possible, from actual want. My own business is good, and am kept quite busy, so that I can find but a few moments to spare at a time to attend to correspondence. The *Pharmacist* we shall have out, if possible, about the 25th of this month. We will have it published in Philadelphia if by that time we cannot find any printer in this city ready to do it. I am busy getting matter ready.... Remember me kindly to all inquiring friends, and believe me, as ever,

"Your friend,

"Albert C. Ebert."

Dispensing Difficulties.

Sir,—I quite agree with "T. B." and also with Mr. Clark as to the inadvisability of making such material alterations in prescriptions as carried out by Mr. Wilkinson, merely for the sake of presenting the medicine in a convenient form for administration. Suppose, for instance, the patient should the next time the medicine was required send the prescription elsewhere; the result would be a great deal of vexation and annoyance to either one chemist or the other, caused by the patient's dissatisfaction with the variable effect of the medicine.

My plan is, whenever a soft extract is ordered, such as rhei, calumb. or gentian, to weigh out the required quantity, transfer it to a slab, and then apply a gentle heat with the gas stove until I think the extract has acquired a proper consistence for working. By adopting this means I have generally been able to turn out a satisfactory pill, and I think in every respect complied with the wishes of the prescriber.

For the second prescription given by Mr. W. in the current number of the Journal, I should use the pulv. ext. coloc. co., allowing, of course, a percentage for the loss of moisture.

Hackney, Nov. 27th, 1871. F. W. S.

Sir,—I am to some extent responsible for the reflections cast on my unhappy city by one or two of your correspondents, as I omitted to report some remarks made by myself and others when Mr. Wilkinson's paper was read. The substitution of hard extract for the ordinary soft form was recommended in the "difficult" formulæ mentioned.

I do not remember, however, that there was any remarkable outburst of indignation when Mr. Wilkinson spoke of reducing the quantity of oil of cinnamon in one case; perhaps some of us failed to distinguish the moral difference between putting the quantity only that could be absorbed by the pill-mass, and adding the full quantity and then squeezing part of it out on the pill machine and fingers, or driving it off by the aid of a warm mortar or slab. Let him that is without sin amongst us (if sin it be) cast the next stone.

We who know Mr. Wilkinson best knew that he was too intelligent and conscientious a man not to communicate with the prescriber when practicable or necessary.

F. Baden Benger,

Hon. Sec. Manchester Chemists' Association.

Manchester, Nov. 28th, 1871.

Sir,—In reply to Mr. Wilkinson's request, that I would prove my assertion that the material alterations he proposes are unnecessary in the cases given, I would submit that if the extracts are, as the Pharmacopœia directs, "evaporated until of suitable consistence for forming pills," there will be no difficulty; but if they are not in a condition fulfilling the above requirement, it is surely better to take the trifling trouble of further evaporation than to adulterate.

A more excellent way of making the iron, etc. pills than the certainly handy one of throwing out anything troublesome, is to subtract five grains of water from the sulphate of iron, and add that quantity of wax to the oil of cinnamon. By this means the whole of the component medicines are combined in a perfectly manageable mass without increase of weight. T. B.

Stockton, 28th Nov., 1871.

Sir,—I see in the Journal of last week that Mr. Wilkinson, in speaking of prescriptions which, if dispensed accurately as prescribed, cannot be formed into pills at all, gives the following as an example, stating that it forms a mass the consistence of treacle:—

℞. Podophylli,
Scammon., ana gr. xij
Ext. Rhei gr. xlviij
Ol. Cinnamon ♏xxiv.
Ft. pil. xxiv.

I find it may be easily formed into firm and tolerably hard pills by using the powdered extract of rhubarb (of course allowing for loss of moisture), and adding to each pill a grain of calcined magnesia and powdered tragacanth, so forming a 5-grain pill. The oil of cinnamon should be dropped upon the whole of the magnesia, made into a mass and divided as quickly as possible, putting the pills into a bottle.

This, I think, is following the suggestion of your correspondent "T. B.," presenting the medicine in such a form as to be taken without inconvenience, and at the same time avoiding making any material alteration in the prescription with the physician's approval.

I enclose some of the pills made in the manner described.

Birmingham, Nov. 28th, 1871. James Spencer.

[*⁎* The pills forwarded by our correspondent appear to be of convenient size, well made and of good consistence.—Ed. Pharm. Journal.]

Prescribing and Dispensing.—Mr. George Mee writes in reference to the article published last week under this title, for the purpose of defending London physicians, and of describing his own experience of the caligraphy, chemistry and posology of their prescriptions. But he is quite mistaken in supposing our remarks to have been applied specially to London physicians.

G. Jenkins.—See the second page of the advertising sheet.

"*Logwood.*"—The preparation is made by Messrs. Savory and Moore.

G. M. Wilkins.—We do not know of any published process. Apply to Mr. Robbins, Oxford Street.

Sydney March.—We know of none.

G. J. A.—It is probable that the free acid decomposes the citrate.

J. P.—After having been in the trade fourteen years, and having passed the Modified examination two years ago, it ought to be unnecessary for you to study in order to pass any examination as to competence as a pharmacist. We do not find your name on the Register, or amongst those who have passed the Modified examination.

T. W.—We have examined the Regulations, and think that you have just cause of complaint.

J. B. B.—A few grains of bicarbonate of soda added to good fresh milk will preserve it for some days.

"*Spes.*"—Probably "Plummer's Pill," but it is difficult to pronounce decidedly in the absence of the prescription.

Communications, Letters, etc., have been received from Mr. G. Wilcox, Dr. De Vry, Mr. G. C. Druce, Mr. W. W. Stoddart, Mr. H. Kingscote, B. S., "Zeno," "A Founder," "Puzzled."

THE SUBSTITUTION OF PROPORTIONAL OR RELATIONAL NUMBERS FOR SPECIFIED WEIGHTS AND MEASURES IN THE DESCRIPTION OF PROCESSES IN THE PHARMACOPŒIA.*

BY PROFESSOR REDWOOD.

One of the questions that will necessarily arise in connection with the preparation of a new edition of our Pharmacopœia, is that of the weights and measures to be authorized or recommended for use in prescribing, dispensing and compounding medicines. The committee by whom the present edition of the British Pharmacopœia was prepared have alluded, in the preface to that work, to two "grave defects" in the system of weights principally employed in the description of pharmacopœia processes, namely, "the absence of any denomination of weight between the grain and the avoirdupois ounce of 437·5 grains, and the fact that the ounce is not a simple multiple of the grain;" and they have given, and to some extent used, a second or alternative system,—the metrical system, in which those, or similar, defects do not exist. This more perfect system having been thus approved, and having been adopted in most Continental countries and in this country for the purposes of science; moreover, the substitution of this system for British weights and measures being now sanctioned by law, and a knowledge of it being included among the qualifications which pharmaceutical chemists are expected to possess,—it becomes important to consider whether we cannot adopt an arrangement in the Pharmacopœia by which the employment of metrical weights and measures would be facilitated and promoted. Instructions for the use of these weights and measures in volumetric testing are given in the present edition of the Pharmacopœia, but with this exception, the British system is used, and the processes are so constructed that the application of the other system, in many instances, involves a good deal of calculation.

Yet, notwithstanding the fact, as thus shown, that there are defects in our system of weights, especially as applied to pharmacy, and some strong grounds for exchanging this system for another, I do not think the time has arrived at which it would be judicious or safe, in the administration of medicine, entirely to replace British weights and measures by those of the metrical system. Such a change, if it were now suddenly made, would be distasteful and embarrassing to a large proportion of those for whose use the Pharmacopœia is intended; and this, I believe, applies quite as much to medical as to pharmaceutical practitioners. There are, however, many physicians and pharmacists who are favourable to, and prepared for, the change, and by whom an arrangement of the Pharmacopœia that should afford easy means for effecting the transition from one system to the other, would be looked upon as a step in the right direction.

Assuming, therefore, that this change is desirable, and indeed inevitable, but that it ought to be brought about gradually, we may profitably consider what are the means best suited for accomplishing such an object.

There are two ways in which a gradual change might be introduced. One is to attach to each of the formulæ of the Pharmacopœia, as now constructed, a separate column of figures, representing the equivalent weights and measures according to the metrical system, leaving it to the operator to adopt whichever system he may prefer; and the other is to substitute proportional or relational numbers for specified weights and measures, such numbers being equally applicable to either system.

There are some difficulties in the way of carrying out either of these methods. If we adopted the first, it would be found that in representing the equivalents of our system in terms of the other, it would be necessary to use such a multiplicity of figures as would prove cumbrous and inconvenient in their practical application. Moreover, to be consistent, the same method of giving the equivalents in terms of the alternative system ought to be extended to every part of a process in which weights or measures are expressed, including the application of tests; and this, if fully carried out, would greatly add to the length and intricacy of the descriptions of our processes, and tend to render them obscure. These objections appear to present insuperable obstacles to the adoption of this as a general method of describing the processes, although there are a few instances in which it might be used with advantage.

With reference to the second method, the principal difficulty in the way of its being applied arises from the defect, already alluded to, in our system of weights, namely, that the ounce is not a simple multiple of the grain; for as the quantities represented in several of our processes, as they now stand, are expressed partly in grains and partly in ounces, it is sometimes impossible to give the proportions of the ingredients in whole numbers. There is also another difficulty, if liquids are to be measured volumetrically, and solid and liquid ingredients are used in the same process, arising from the necessity of referring to two different standards, one for the solids and the other for the liquids; for not only would this entail the use of different words to indicate the signification of the numbers when so applied, but in many cases the numbers would not represent the proportional relation of the parts. These difficulties, however, might be met, and in a great measure obviated, by altering the proportions of the ingredients used in some of the processes, attaching to the numbers short affixes which should define their meaning, modifying the mode of arranging or constructing some of the formulæ, and omitting the application of the method in a few instances.

I have been for some time endeavouring to apply this as a general method to be used in describing processes in the Pharmacopœia; and my object on the present occasion is to explain the way in which I think it might be made to accomplish the desired object; I wish also to elicit the opinions of practical pharmacists and others with reference to it.

The first thing required is a definition of terms to be employed in connection with the numbers representing relative quantities, for as these numbers would sometimes represent weight and sometimes volume, it would be necessary to distinguish one from the other. The term *part* might be used to represent *weight*, and the term *measure* to represent *volume*. These terms are commonly employed with such significations, and if it was clearly defined that *parts*, when used in connection with the proportional or

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, Dec. 6, 1871.

relational numbers, always meant parts by weight, and that *measures*, when similarly used, always meant parts by volume, no mistake would be likely to occur. If, however, it should be thought desirable in some instances to be more explicit, the term *part* might be extended to *part by weight;* but it would be very undesirable to use more words than are absolutely necessary, as these terms would have to be frequently employed, not only in setting out the formulæ for the ingredients, but in the instructions for conducting the processes, and also in describing the application of tests. In cases in which the terms *part* and *measure* would both occur in the same process, the *measure* would be the water-measure of the unit of weight, whatever that might be.

With a clear understanding of the meaning of the terms *part* and *measure*, as thus defined, their application in the construction of formulæ would, in most cases, be sufficiently simple and easy, and the interpretation of the descriptions given by means of them would admit of no doubt.

The following examples will serve to illustrate the application of the proposed method to some of the processes of the Pharmacopœia:—

Antimonial Powder.

Take of

Oxide of Antimony	1 part.
Phosphate of lime	2 parts.

Mix them thoroughly.

Diluted Acetic Acid.

Take of

Acetic Acid	1 measure.
Distilled Water	7 measures.

Mix.

These are two of the most simple cases that would occur; the numbers used representing the proportions of the ingredients, in one case by weight, and in the other by volume.

As another example, we may refer to the process for *spirit of camphor*, in which an ounce of camphor is dissolved in nine fluid ounces of rectified spirit. The formula would be written:—

Take of

Camphor	1 part.
Rectified Spirit	9 measures.

Dissolve.

In this case, whatever weight might be used to represent 1 part, the 9 measures would be nine water-measures of that weight. It is obvious, however, that the numbers here are not strictly proportional numbers, for the spirit and camphor do not bear the relation of 9 to 1 either by weight or volume. The numbers might be more correctly represented as relational numbers. They indicate the relation of a weighed quantity to a measured quantity. Even the terms part and measure, as used in this case, might be taken exception to, if considered apart from the definition already given. Viewed in that way, without reference to the definition, the terms would be more explicit, if for measures was written unit-measures, the measure being a measure of the unit of weight; but even this, without further explanation or definition, would not convey a correct impression, for the spirit, if estimated as spirit, is not 9 measures of the unit of weight, but 9 water-measures or nine times the measure of the unit-weight of water.

It thus appears, therefore, that the terms *part* and *measure*, or, I believe, any other equally and sufficiently concise terms, must be used conventionally, for the specific purpose required, and subject to a definition. When so used, the terms are convenient and appear to answer the required purpose. They are applicable to either of the alternative systems of weight and measure, for while we have the grain and grain-measure, the ounce and fluid ounce or ounce measure, and the pound and sixteen-ounce measure, all of which are recognized and have long been used in this country,—the metrical system includes the cubic centimetre and the litre, which are the water-measures of the gram and the kilogram.

In some of the processes that are more complicated than those I have referred to, difficulties in the way of applying the proposed method appear to exist, which, however, are easily removed by slightly modifying the arrangement of the formulæ. The process for chloroform, as given in the Pharmacopœia, is one of this description. The formula, as it now stands, includes not only the ingredients employed for the production of the crude chloroform, but also those used in the subsequent purification of the product. The description would be rendered more simple and effective, and, at the same time, better suited for the use of proportional and relational numbers, if the formula representing the ingredients contained only those used in the first operation, and the substances used in the purification were merely named when referred to in the instructions for conducting the subsequent part of the process; it would then run as follows:—

Take of

Rectified Spirit	2 measures.
Water	30 measures.
Chlorinated Lime	10 parts.
Slaked Lime	5 parts.

Put the water and the spirit into a still capable of holding three or four times as much as the bulk of the ingredients introduced, and having raised the temperature of the mixed liquid to 100°, add the chlorinated lime and slaked lime, and mix the whole thoroughly. Connect the still with an efficient condenser, terminating in a narrow-necked receiver, and apply heat so as to cause distillation to commence, taking care to withdraw the fire as soon as the process has been well established. When the distilled product amounts to 3 or 4 measures the receiver is to be withdrawn, and its contents mixed with about 5 measures of water in a bottle of ample size in which they can be well shaken together. The mixture is now to be left at rest for a few minutes, when the liquids will separate into two strata of different densities. Let the lower stratum, which constitutes crude chloroform, be washed by agitating it in a bottle with a tenth of its volume of distilled water. Allow the chloroform to subside, withdraw the water, and repeat the washing twice in the same way with similar portions of distilled water. Add to the washed chloroform an equal volume of sulphuric acid, care being taken that the acid thus used is entirely free from nitric or nitrous acid; shake them together in a stoppered bottle for five minutes, then allow the mixture to settle, and transfer the upper stratum, consisting of purified chloroform, to a flask or retort, with about one-twentieth of its weight of dry chloride of calcium and a fourth of that quantity of perfectly dry slaked lime. Let them stand together for about an hour, then, an efficient condenser being attached, distil over the pure chloroform by means of a water-bath. Preserve the product in a cool place in a bottle furnished with an accurately-ground stopper.

The process for ether would be treated similarly, and would be described as follows:—

Take of
Rectified Spirit . . . . . 12 measures.
Sulphuric Acid . . . . . 10 measures.

Mix the acid and spirit together in a glass matrass capable of containing at least twice as much as the bulk of the ingredients introduced, and, not allowing the mixture to cool, connect the matrass by means of a bent glass tube with a Liebig's condenser, and distil with a heat sufficient to maintain the liquid in brisk ebullition. As soon as the ethereal fluid begins to pass over, supply fresh spirit through a tube into the matrass in a continuous stream, and in such quantity as to equal the volume of the fluid that distils over. For this purpose use a tube furnished with a stopcock to regulate the supply, connecting one end of the tube with a vessel containing the spirit raised above the level of the matrass, and passing the other end through a cork fitted into the matrass. When about 42 measures of liquid have distilled over, the process may be stopped. For the purification of this crude ether, mix it with a third of its volume of saturated solution of chloride of calcium and a little slaked lime (about a fourth part of the weight of the chloride of calcium solution), and, having shaken them together in a bottle, leave them at rest for ten minutes, then pour off the light supernatant fluid, and distil it with a gentle heat until a glass bead of specific gravity of 0·735 placed in the receiver begins to float. The ether and spirit retained by the chloride of calcium and by the residue of each rectification may be recovered by distillation, and used in a subsequent operation.

Among processes the descriptions of which would require to be modified much in the same way as the two last noticed are those for the preparation of the alkaloids. These are the most complicated processes we have, and if the use of proportional and relational numbers can be made available in describing them, we may conclude that the method would not fail on account of the complicated nature of the instructions to be given. The process for *digitalin* may be taken as a test of the applicability of the method in such cases. It would be given as follows:—

Take of

Digitalis Leaf, in coarse powder	Of each a sufficiency.
Rectified Spirit	
Distilled Water	
Diluted Acetic Acid	
Purified Animal Charcoal	
Solution of Ammonia	
Tannic Acid	
Oxide of Lead, in fine powder	
Pure Ether	

Digest 100 parts of the digitalis with 400 measures of the spirit for 24 hours at a temperature of 120°, then put them into a percolator, and when the tincture has ceased to drop pour 400 measures of the spirit over the contents of the percolator, and allow it to slowly percolate through. Distil off the greater part of the spirit from the tincture, and evaporate the remainder over a water-bath to the consistence of a soft extract. Mix this extract with 12 measures of diluted acetic acid, and digest the solution thus formed with 1 part of purified animal charcoal; then filter, and dilute the filtrate with distilled water until it amounts to 50 measures. Add solution of ammonia nearly to neutralization, and afterwards add 1 part of tannic acid dissolved in distilled water. Wash the precipitate that will be formed with a little distilled water; mix it with a small quantity of the spirit and 1 part of the oxide of lead, rubbing them together in a mortar. Put the mixture into a flask, and add to it 10 measures of the spirit. Raise the temperature to 160°, and keep it at this heat for about an hour. Then add 1 part of purified animal charcoal. Put it on a filter, and from the filtrate carefully drive off the spirit by the heat of a water-bath. Lastly, wash the residue repeatedly with pure ether, and dry it.

If, with reference to cases such as this, it should be said that the instructions would be more easily followed in carrying out the processes if the quantities referred to were represented by specified weights and measures, the objection might be admitted without material detriment to the value of the proposed method; for these processes, the only ones in which such complicated instructions occur, are not given with a view to their being carried out by pharmacists in general, nor should they be undertaken by any but those accustomed to such operations, and to whom the modified instructions would supply all the information required.

Thus far, and in cases similar to those I have noticed, which constitute a great majority of the Pharmacopœia processes, the application of the proposed method would not be attended with any difficulties that could not be overcome by such slight modifications as I have indicated; and in some of these and other cases it would, I think, facilitate improvement of the processes by causing a more uniform relation and more simple proportions to be established than now exist among the ingredients of compound medicines.

But I must now refer to cases in which more serious difficulties are presented. There are a considerable number of processes in the Pharmacopœia in which the ingredients do not bear a simple numerical relation to each other, and several of these, containing powerful medicines, are very important remedies. Thus, we have *liquor arsenicalis, liquor arsenici hydrochloricus, liquor atropiæ, liquor atropiæ sulphatis, liquor morphiæ acetatis, liquor morphiæ hydrochloratis, liquor sodæ arseniatis,* and *liquor strychniæ,* all containing 4 grains of the active ingredient in a fluid ounce of the solution, or 1 part in 109·375 measures. Now, in these cases and others of a similar description, as the proposed method is not applicable to the existing processes, it would be necessary to make the processes applicable to the method by altering the proportions of the ingredients. In the event of such an alteration being made in the medicines named, it would probably be considered desirable to make them all contain 1 per cent. of the active ingredient. But a proposition to that effect, although much might be said in its favour,—and I should be disposed to advocate it,—would nevertheless raise some questions which ought not to be overlooked. The existing proportions have evidently been adopted to suit our system of weights and measures. Four grains in the fluid ounce, or half a grain in the fluid drachm, are convenient proportions suited to the particular circumstances under which we have been accustomed to prepare, dispense and administer the medicines. The proportions have been made to suit our compounding and dispensing appliances. If the proportions were altered to 1 in 100, we should simplify the numerical relation of the ingredients, but not the proportion of the active ingredients to the measures commonly used for dispensing and administering medicines, for a 1 per cent. solution would contain 4·375 grains in a fluid ounce, or 0·5468 grain in a fluid drachm.

If this method were adopted in preparing the solutions referred to, and other preparations that would come into the same category with them, it would be necessary to provide measures of ample size graduated to grain-measures instead of fluid ounces. Such measures are now supplied by dealers in chemical apparatus, but they are not in common use. Sets of grain-weights up to 10,000 grains would also be desirable. The ease and rapidity with which processes would be performed in which proportional and relational numbers are used would greatly depend upon using the same denomination of weight or measure throughout a process, and where measure as well as weight is indicated in the same process, using a denomination of measure that corresponds to the unit of weight, as for instance, using the grain-measure in connection with the grain, and the cubic centimetre in connection with the gram.

One of the objects contemplated in the proposed change being the establishment of a more simple quantitative relation of the ingredients in compound medicines, it would, I think, be desirable in some cases to depart from the usual practice of measuring liquids. I would suggest, therefore, that in medicines containing solid and liquid ingredients, if the products be of such consistence that they would be prescribed and dispensed by weight, the liquid ingredients contained in them should be apportioned by weight, with the view of simplifying the proportions. Thus, for instance, in confection of opium, as now prepared, neither the opium nor the compound powder of opium is a simple proportion of the whole, because the syrup is used by measure; whereas if the syrup as well as the powder were ordered by weight, the proportions could easily be made simple and definite. The formula now is,

Compound powder of opium	192 grains.
Syrup	1 fluid ounce.

Proportion 1 in 4, nearly.
I would make it,

Compound powder of opium	1 part.
Syrup	3 parts by weight.

Proportion of compound powder of opium 1 in 4, and of opium 1 in 40, exactly.

This is a case in which it would be desirable to extend the term "parts" to "parts by weight," as applied to the syrup, with a view to greater explicitness.

Confection of scammony would be treated similarly, and so also would the pill-masses which contain liquid excipients or essential oils. By adopting this and other proposed changes, we might obviate the necessity there now is of using the term "nearly" in representing the proportions of the ingredients in compound medicines.

I have already alluded, among the modifications required to make the proposed method practically applicable to all the processes of the Pharmacopœia, to the omission in a few instances of the use of proportional or relational numbers. It will be obvious that in cases in which the formulæ are intended to represent the quantities of the medicines ordered which are to be administered at one time, as occurs in the formulæ for *enemata*, reference must be made to specified weights and measures. In such cases, of which there are only a few in the Pharmacopœia, one of two methods must be adopted. We must either express the quantities of the ingredients by weight and measure, putting the two sorts of weight and measure in separate columns,—a method I have already alluded to,—or we may first describe the process by using proportional or relational numbers, and then represent the doses by weight or measure, according to the alternative systems.

In the formulæ for *enemas* I think the former of these methods the best, because each of the formulæ is in fact a prescription, which is inserted in the Pharmacopœia to save the physician trouble. The only change I would propose to make in these formulæ would be the introduction of a second column of figures representing the quantities according to the metrical system; thus,

Enema of Aloes.

Aloes	40 grains.	or	2·59 gram.
Carbonate of potash	15 grains.		0·97 gram.
Mucilage of starch	10 fl. ounces		283·49 cubic centimetres.

The occasional placing in apposition of the equivalents of the two sorts of weight and measure, in this way, would have the good effect of showing the relation existing between them.

There are two other classes of preparations in the Pharmacopœia, in which the processes include the apportionment of the doses, namely, the *suppositories*, and the *lozenges*. I would treat these cases differently from that of the *enemas*.

With reference to the suppositories, the formulæ for all of which are very simple, it would only be necessary to substitute parts for grains in connection with the ingredients, and in representing the weight of each suppository to give it in grams as well as grains:—

Tannic Acid Suppositories.

Take of

Tannic Acid	36 parts.
Benzoated Lard	44 parts.
White Wax	10 parts.
Oil of Theobroma	90 parts.

Melt the wax and oil of theobroma with a gentle heat, then add the tannic acid and benzoated lard, previously rubbed together in a mortar, and mix all the ingredients thoroughly. Pour the mixture while it is fluid into suitable moulds to form suppositories, each of which shall weigh about 15·4 grains, or 1 gram.

In the formulæ for lozenges more considerable alteration would be necessary, but in making such alteration the processes might be simplified, as far as the descriptions are concerned, and the proportions among the ingredients made definite. One instance will illustrate the whole:—

Reduced Iron Lozenges.

Take of

Reduced Iron	10 parts.
Refined Sugar, in powder	250 parts.
Gum Acacia, in powder	15 parts.
Mucilage of Gum Acacia	30 parts.
Distilled Water	a sufficiency.

Mix the iron, sugar and gum, and add the mucilage and water to form a proper mass. Divide into lozenges, each of which shall contain 1 grain, or 6·4 centigrams, of reduced iron. Dry them in a hot-air chamber with a moderate heat.

The only remaining part of the processes and descriptions in the Pharmacopœia that I have to refer to is that which relates to the applications of tests. There is no difficulty here in the employment of proportional and relational numbers, provided the rule be adhered to of always using the same denomination of weight or measure throughout a process; and when measure as well as weight is indicated in the same process, of using a measure that corresponds with the unit of weight. The quantities used in testing are always such as easily admit of the application of this rule, and, in other respects, only a few slight alterations are generally required. The following examples will serve to illustrate the mode of treating cases of this sort.

Vinegar.

Characters and Tests.—A liquid of a brown colour and peculiar odour, specific gravity 1·017 to 1·019. 500 measures of it require at least 451 measures of the volumetric solution of soda, corresponding to 5·4 per cent. of acetic acid ($HC_2H_3O_2$). If mixed with $\frac{1}{45}$ by measure of solution of chloride of barium, and the precipitate, if any, separated by filtration, a further addition of the test will give no precipitate. Sulphuretted hydrogen causes no change of colour. One fluid ounce or 28·349 cubic centimetres, contain 24 grains, or 1·55 grams, of acetic acid ($HC_2H_3O_2$).

Hydrochloric Solution of Arsenic.

Characters and Tests.—A colourless liquid, having an acid reaction. Specific gravity 1·009. Sulphuretted hydrogen gives at once a bright yellow precipitate. 400 measures of it boiled for five minutes with 20 parts of bicarbonate of soda, and then diluted with 2000 measures of distilled water, to which a little mucilage of starch has been added, does not give with the volumetric solution of iodine a permanent blue colour until 808 measures have been added, corresponding to 1 part of arsenious acid in 100 measures of the solution.

One fluid ounce, or 28·349 cubic centimetres, corresponds to 4·375 grains, or 0·283 gram, of arsenious acid.

In this case I have assumed that the process has been so altered as to yield a 1 per cent. solution.

I think I have now referred to the various conditions under which the substitution of proportional or relational numbers for specified weights and measures might be effected. I submit the proposition to the judgment of those members of the medical and pharmaceutical bodies who are anxious to make the British Pharmacopœia a credit to this nation, and available for use in all other countries.

[*The discussion upon this paper is reported at p.* 476.]

A METHOD FOR THE ESTIMATION OF MORPHIA IN OPIUM.*

BY JOHN T. MILLER.

The narcotic power of opium is mainly owing to morphia, the proportion of which in different specimens is subject to great variation. As the appearance of the drug affords no clue to its strength, the pharmaceutist can solve that problem only by the employment of chemical means. A morphiometric method at once "ready, easy, accurate and precise," is still, I believe, as it was when Pereira wrote, a desideratum.

The process given in the British Pharmacopœia is, perhaps, as good as any of the kind, yet it is tedious, and, judging from my own experience, uncertain. Not being satisfied with it, I resolved to try whether a method of moderate accuracy and readiness could be based on the reduction of *iodic acid* by morphia. The scheme did not seem very promising, for that acid is decomposed by many organic bodies besides morphia; but as their action is, for the most part, much slower than that of the alkaloid, I thought it might be possible (supposing such bodies to be present) to separate with sufficient sharpness, their effect from that due to the morphia. It will be seen presently, however, that the chief difficulty met with was not of the kind anticipated.

With a weighed quantity of the sample to be tested, a solution was prepared as free as possible from resinous, mucilaginous and colouring matters; but it was not considered necessary to remove any of the opium principles, as they do not, with the exception of morphia, decompose iodic acid. To a certain volume of this solution some aqueous iodic acid was added, and after the lapse of a few minutes the liberated iodine was washed out by shaking the mixture with carbon disulphide. The *sample colour* thus produced was then compared with another—the *standard colour*—prepared in the same manner, but from a solution of morphia of known strength; and their intensity was equalized by adding carbon disulphide to the deeper. From the data thus obtained the percentage of morphia in the sample was calculated.

When a number of specimens had been thus examined, they were next tested by the B. P. process. The results obtained were higher—sometimes considerably higher—than those yielded by the former method. However, as the precipitates were not pure, each was washed with half a fluid ounce of cold chloroform, dried and reweighed. All had lost more or less in weight; but very little of the matter dissolved out could be morphia, as a fluid ounce of chloroform takes up only about 0·1 grain of that substance. A portion of each washed precipitate was next accurately weighed off and made into a solution similar to the standard, with which it was carefully compared in reducing power, and the amount of real morphia in the precipitate thereby determined. The accordance of the two series of figures was now much closer than before; but a suspicion arose that some of the reduction results were too low, and soon reached certainty. To clear up this point numerous experiments were tried, only a few of which need be mentioned:—

1. Some *narcotine* was added to the standard morphia solution, then iodic acid, and after the mixture had stood a few minutes, it was shaken with carbon disulphide. The feeble colour of the latter showed plainly that it contained less than the usual quantity of iodine.

2. The experiment was repeated, but with this difference, viz. the shaking with carbon disulphide was performed immediately after adding the iodic acid. The full colour was now obtained, the liberated iodine having been seized by the disulphide before the secondary reaction could take place.

3. Similar experiments were tried with *codeine*, the invariable result being a diminution in the amount of iodine set free.

4. *Thebaine* was found to act in the same direction as codeine.

5. Iodine water, when added to a slightly acid solution of *papaverine*, produces a red-brown precipitate, which gives with chloroform a yellow or brown solution; but carbon disulphide abstracts the iodine from the compound and liberates the papave-

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, Dec. 6, 1871.

rine. The presence of the latter in the sample solution is, therefore, of no consequence.

6. Though solution of *narceine* does not reduce iodic acid, yet after being heated with lime or potash, it has that effect. But the proportion of narceine existing in opium appears to be so minute, there can be no risk of error from this source.

The requisite conditions being now better understood, the samples were examined afresh by the reduction process, and this time the results were deemed satisfactory.

This sketch of the course of the inquiry may serve to explain some parts of the process finally adopted, which I will proceed to describe :—

Apparatus.—Three strong tubes of colourless glass, like ordinary test-tubes in form, about eight inches in length and of exactly equal bore, which should be about half an inch. At first I used graduated tubes, but afterwards found it better to employ separate measures of smaller calibre, viz. a pipette to deliver 100 grain-measures; a tube-measure for 50 and 100 grain-measures; and a smaller one for 5, 7·5 and 10 grain-measures.

Standard Solution of Morphia.—Weigh off accurately one grain of pure and well-dried morphia, and dissolve it in 50 grain-measures of diluted sulphuric acid, B. P., and sufficient distilled water to make the volume exactly 1000 grain-measures. This solution will keep without appreciable change for some weeks.

Solution of Iodic Acid.—Place in a flask 100 grains of iodine, 100 grains of potassium chlorate, 1 fluid drachm of strong nitric acid and 2 ounces of water. Heat the mixture until the iodine is perfectly oxidized; nearly neutralize with sodium carbonate, then add an excess of solution of barium chloride. Wash the barium iodate by decantation, and boil it for half an hour with a fluid drachm of strong sulphuric acid and 3 ounces of water. When cold, filter and add water to make the bulk 6 fluid ounces.

Sample Solution.—If the opium is in the moist state, dry 100 grains on the water-bath, and after noting the loss in weight reduce it to *fine* powder. Put 20 grains of the powder into a two-ounce flask with 1 grain of oxalic acid and half a fluid ounce of alcohol sp. gr. 0·838, and having attached a condensing-tube to the flask, place the lower part of the latter in water hot enough to cause the spirit to boil gently, and continue the boiling for half an hour. Filter into a porcelain dish, and wash the residue with half a fluid ounce of hot spirit. Add to the filtrate half an ounce of water, and evaporate down to about a quarter of an ounce, stirring frequently, then add an ounce of cold water. After the mixture has stood for ten minutes or so, remove the precipitated resinoid matter by the filter, and wash it with a little cold water, adding the washings to the filtrate. Boil the latter with 10 grains of slaked lime for two or three minutes, filter, and wash the calcium compounds with hot water. Slightly acidulate the filtrate with solution of oxalic acid, and evaporate it down to about a fluid ounce. After cooling, add 12 grains of caustic potash and set aside for a quarter of an hour; then filter, and wash the precipitate with a drachm of liquor potassæ, diluted with two or three times as much water. Divide the filtrate into two exactly equal portions: pour one of these into a 1000-grain measure, add 100 grain-measures of diluted sulphuric acid, B. P., and water up to the mark and mix well. Finally, shake the small quantity of solution required for experiment—about half an ounce—with a fourth of its bulk of carbon disulphide, and pass it through a filter.

The Experiment.—Measure off with the pipette 100 grain-measures of the sample solution, and transfer it to one of the trial-tubes, add 100 grain-measures of carbon disulphide, and lastly, 50 grain-measures of iodic acid solution; then immediately close the tube with a sound cork and shake briskly for *half a minute*. The rose-coloured solution of iodine quickly subsides, but its brightness is sometimes rather obscured by a slight filmy deposit on the glass. In this case pour the contents of the tube into a clean one. Take next 100 grain-measures of the standard solution of morphia, and using a fresh tube, repeat the operation just described. Compare now the two rose-tinted liquids by holding the tubes side by side between the eye and a white cloud, or placing them against thin white paper attached to a window-pane. If the colours are equal in intensity, the powdered sample contains 10 per cent. of morphia. If unequal, add to the deeper one carbon disulphide in small successive measured quantities—say of 5 or 10 grain-measures at a time, as may seem necessary,—gently mixing it in with a glass rod. When by this means the tints have been rendered equal in depth, the calculation is simple.

Let v = volume in grain-measures of standard colour;

Let v' = volume in grain-measures of sample colour;

then $\frac{v' \times 10}{v} = x$ = percentage of morphia in powdered sample.

And if w = percentage loss of weight in drying, $\frac{100 - w \times x}{100}$ = percentage of morphia in moist sample.

Precaution.—The carbon disulphide used must remain colourless when shaken with solution of iodic acid.

In order to test the ability of the eye to discern slight inequalities of tint, the relative quantities of iodine in the standard and sample colours were sometimes estimated at the end of an experiment by Dupré's method. This was done by removing the supernatant aqueous liquid with a pipette, washing the solution of iodine with distilled water, transferring it to a stoppered bottle, and adding, with vigorous shaking, weak chlorine water from a burette until the colour just disappeared. The results are given in the subjoined table, and show, I think, that the eye has a fair claim to be trusted. When a number of morphia determinations have to be made the use of this iodimetric process is convenient, as only a single daily reference to the standard is then needed.

The time required for determining the morphia value of opium on the above plan is about two hours and a half. As regards accuracy and reliability, I may state, that so far as my experiments have gone —and they have not been few—the results have appeared, after careful scrutiny, to be nearer approximations to the truth than those obtained by the ordinary methods by precipitation. I have, therefore, much confidence in the process. Nevertheless, I am ready to admit that an analytical method which deals, as this does, with a substance so complex and variable in composition as opium, must have an extended trial before its reliability can be placed altogether beyond doubt.

Table of Results.

Sample.	Percentage of crude morphia obtained by B. P. process.	Weight of precipitate after washing with chloroform.	Amount of real morphia in precipitate estimated by reduction process.		Percentage of real morphia in sample as determined by reduction process.	
			Colorimetric.	Iodimetric.	Colorimetric.	Iodimetric.

[*The discussion upon this paper is printed at p.* 477.]

THE SYRUP AND RESIN OF TOLU, AND TINCTURE OF CINNAMON.*

BY A. F. HASELDEN, F.L.S.

The legitimate field of operation for the pharmaceutist is pharmacy, but, wide as that field may be, it is not always easy to supply the demand for original matter; nevertheless, facts not necessarily known to all do occasionally spring up, and which are considered worth recording.

Syrup of tolu, like many other preparations of the Pharmacopœia, would seem at first sight to be a very unimportant one; it has, however, been made more prominent by some pharmaceutists since the introduction of the hydrate of chloral. At any rate, there is more in the mode of preparation than is commonly given credit for. Though it is well known to you, I must, in order to make my observations clear to some, give the Pharmacopœia process. Balsam of tolu is boiled with distilled water for half an hour in a lightly-covered vessel, distilled water being then added, if required, to make up the quantity specified. When cold the liquor is filtered, and the sugar, being added, is dissolved by the aid of a water-bath heat, the product having a specific gravity of 1·330. The result of filtering, when cold, is the separation of small particles of resinous matter, with a mixture of cinnamic and benzoic acid floating upon the surface of the liquor,—a circumstance of which any student would or should be cognisant. If filtered whilst hot, this combination of acid would remain suspended, although not dissolved, in the cold syrup, which, when used as an adjunct in cough preparations, might induce, and has been known to do so, the very irritation or tickling about the fauces which it was intended to allay. In the last edition of Royle's 'Materia Medica' it is stated that the syrup of the P. B. is about twice as strong as that of the P. L.; this is an error of calculation, as the preparations are as near as possible identical. The older and harder the balsam of tolu, the larger the crop of crystals will be. On making the syrup, I separated from one quantity of ℥iij ʒvj of balsam 14 grains of crystals; and three or four months later, from a similar quantity of the same balsam, 34 grains. The quantity of balsam ordered for making the syrup appears larger than necessary, inasmuch as it is not exhausted; but that is not a matter of much moment, the object being, as I am told, to obtain a full-flavoured syrup. Besides this mixture of cinnamic and benzoic acids, which I hope to utilize, though the quantity obtained is small, there is the resin remaining. This I use, as undoubtedly many others do, for coating pills and some descriptions of granules.

In the Conference 'Year-Book of Pharmacy' for 1870, at page 53, may be found the following form for a pill-varnish, viz. Ether, 100 parts; *Balsam* of Tolu 10 parts; Colophonium 1 part; Absolute Alcohol 10 parts: macerate until the resin is dissolved. The tolu balsam must be previously digested four hours in hot water, and then dried and added to the rest. The mode of coating is by putting the granules with sufficient of the varnish, which is found out by practice, into a shallow circular porcelain evaporating-dish, and quickly shaking them round. The process of drying may be quickened by throwing them into a sieve, and keeping up the rotatory motion. Pills in large quantities in the same way; in small quantities, in pots having an egg-shaped bottom. I have employed a similar varnish for several years, but I simplify the form for preparing the solution. In the first place, I omit the colophony, or resin, as being neither necessary nor agreeable; and, instead of digesting *fresh* balsam of tolu in hot water, I take the resin of tolu, the waste product after preparing the syrup. I use less ether and more alcohol, thereby obtaining a less costly result, and one equally good,—the only advantage of a large quantity of ether being the drying of the varnish in a shorter time; but, for general purposes I find it dries quickly enough. If very rapid drying be necessary, methylated chloroform is the best solvent. My proportions are the following:—Resin of Tolu 3 parts; Rectified Spirit 6 parts; Methylic Ether 2 parts; well shake until all that will is dissolved. Use the clear solution. Iodide of iron pills are well preserved by this coating, and also granules of secale cornutum, as suggested by Dr. Skinner, of Liverpool. For preserving secale in a portable state the plan is good; for, if there should be any difficulty in swallowing the granules, they can be readily crushed into a coarse powder and taken with water. I have also employed this solution as a liquid-stopping for the teeth, applied by means of cotton wool, and have found it more manageable and less disagreeable than the various solutions of mastich. If it could be deprived of colour and odour without destroying its adhesive quality, it would be

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, Dec. 6, 1871.

better still. I have tried for this, but, at present, without success.

Following a train of thought, I am led on to oil of cinnamon, which, by exposure to the air or the influence of oxygen, is converted into crystalline matter, hydrated cinnamic acid; and from this I turn to simple tincture of cinnamon, some of which, having been prepared a long time, has become sadly decomposed and altered for the worse. What I am about to state will, I think, be worth the attention of those who may edit the next edition of the P. B. In the London Pharmacopœia there were two tinctures of cinnamon, the simple and compound; the former composed of cinnamon and proof spirit; the latter, of cinnamon, cardamom, long pepper, ginger and proof spirit; the proportion of cinnamon in the compound preparation being only one-fifth of that in the simple. In the P. B. the simple tincture is alone retained. Of the two, I believe that the compound would have been more serviceable. As a warm flavouring menstruum or adjunct, the simple tincture possesses little or no real advantage over good cinnamon water; whereas, if a warmer aromatic in addition to cinnamon water were desirable, the compound tincture would be the very thing; it would answer a twofold purpose, which the simple does not. On the other hand, in addition, I think I can show that there is a positive disadvantage attached to the simple tincture. After long exposure to light in the ordinary position upon the shelf, it becomes much altered; in fact, thick, and throwing down a copious deposit, separable by filtration, leaving a poor solution, very unlike the original; taste and smell much changed, possessing more of a weak storax flavour than cinnamon. Had the menstruum for simple tincture been rectified spirit, the chances of decomposition would have been diminished. Simple tincture of cinnamon is not in daily demand in prescriptions, but it is sometimes. I have seen it prescribed with solution of perchloride of iron as drops (a form of prescribing I have always, as a rule, opposed). The production is not, at any time, a sightly one, being dark green, not unlike ink, even with a bright tincture; but with a decomposed one, though still green, it is not clear. This altered tincture may be rendered bright by filtration (*vide* specimens), but it no longer resembles its primitive condition either in taste or smell. It may be urged that the tincture should not be so old as to have become changed. True, but when a preparation is rarely ordered, its possible defects are forgotten, or overlooked until it is required. The tendency of modern prescribing leans, unfortunately, too much towards novelties, which are frequently dispensed without profit, and not required again until spoilt. But to return to my tincture. I have never seen the compound tincture of cinnamon similarly altered; and I would suggest that a better and more generally useful tincture might be prepared upon the basis of the compound tincture of the P. L., using rather more cinnamon and less cardamoms—for, as it formerly stood, it partook more of the character of cardamom than cinnamon—retaining the other ingredients, and substituting rectified spirit for proof; or if not rectified, at least a stronger spirit than proof. Should it still be considered desirable to retain the simple tincture, I would recommend that it be prepared with rectified instead of proof spirit, as I am of opinion that it would then remain a longer time unchanged.

PHARMACY IN EDINBURGH IN THE OLDEN TIME.*

BY JAMES MACKENZIE.

(*Concluded from page* 446.)

In 1656, the physicians had the matter again revived, during the Protectorate of Cromwell, to whom a memorial was presented. It was then affirmed, that such were the public abuses in matters of medicine that frequent murders were committed, in all parts of the kingdom, by quacks, women, gardeners, and others grossly ignorant.

On the recital of such public abuses the application was again founded in order to obtain a patent. It seems to have been drawn up chiefly by Dr. Purvess, but had the names of seventeen physicians subscribed to it.

The abuses were described under eight distinct heads, which certainly left little unsaid that was likely to carry their point, and, as usual, the poor druggists had a sad time of it, in order to maintain their position with any degree of credit. Under the third head we find the following:—"The unwarrantable vending of drugs, simple and compound, by druggists and apothecaries, not only in common sale but in the dispensing of physicians' receipts, and these generally carious, sophisticated, and every way corrupted, and of this the most deadly poisons, without security taken from the buyer, or any other restraint, as is found by the great difference in medicines in their operatione here from what is found abroad."

But this is not all, for in the fourth abuse mentioned we have the following, which speaks of the exorbitant prices charged for medicines:—"The great gains which the apothecaries have made has so increased their number, that to make them all live there must be a strange extortioning of the lieges; so 'tis no extraordinary thing to charge half-a-crown for a mercurial bolus, not worth three halfpennies; a crown for ane emulsion, not worth a groat; forty pence or 4*s*. sterling for a drop weight of Jesuits Powder, or powdered cinchona, and that to be repeated once in two hours; thus, in an account we find 2700 pounds Scots, or £225 sterling for decoction of sarsa, and £3 sterling for a pint of Lower's Bitter Tincture has been charged and paid; £20 sterling for a course of mercury, and if any of these matters of fact be controverted, chapter and leaf may be cited." See an account of the rights and privileges of the College of Physicians and Surgeons, Edinburgh, supposed to have been written by Dr. Eccles, Edinburgh, in 1707; also Sibbald's Memoirs of the College of Physicians, a MS. in the Advocates' Library.

The physicians were nearly successful in getting from Cromwell all they desired. The patent was made out, sent down to Edinburgh, and everything seemed to be in the most prosperous condition, when once again they were doomed to disappointment; this happened in 1656. In the following year a conference was held in Dundee, at which a deputation of physicians from Edinburgh, and some representatives from the Aberdeen University, met to consider the nature and extent of the powers to be conferred by patent on the physicians. It is said that at this conference the separate interests of the parties were arranged, while the claims of surgery and pharmacy, as may be supposed, engaged no small share of their time and consideration. Thus, in 1657, Edinburgh men were the first to hold what may be termed, at least to some extent, a Pharmaceutical Conference.

Following up this we find, that two young Scotchmen, Andrew Balfour and Robert Sibbald, both of respectable families, went the one to Italy and the other to Holland, in quest of medical knowledge. They afterwards met in France, and being both ardent students of natural history, an intimacy was formed which, on their return

* Read at a meeting of the North British Branch of the Pharmaceutical Society, Edinburgh, November 24th, 1871.

to Edinburgh, was renewed and strengthened. With the view of promoting the study of botany and the cultivation of medical plants, they agreed together to take a small piece of ground in the abbey yards, forming, it is presumed, a portion of the palace gardens. As they proceeded their views expanded, while others became interested in their undertaking. A larger piece of ground was afterwards taken from Trinity Hospital, which has since been known by the name of the Physic Gardens, where, by the unwearied zeal and activity of Dr., afterwards Sir Andrew Balfour, and others, it became the most renowned medicine garden in Great Britain. This was the origin of the Edinburgh Botanic Gardens, now so widely and so justly celebrated, which, curiously enough, as you are all aware, are now under the charge and superintedence of one of the same name as its great founder, Professor Balfour.

During this time the physicians never lost sight of the grand object of their ambition. Meanwhile, the encroachments of the surgeon apothecaries had become insupportable; therefore, to every other and higher motive self-interest infused new vigour into the exertions, which the physicians put forth for the attainment of their object; and, notwithstanding the most strenuous opposition from the surgeons, clergy, nobility and others, and after long discussion of the matter in Privy Council, the charter of incorporation was obtained, *without any restriction on the druggist*, and the great seal appended on St. Andrew's day in 1681.

Immediately on receiving this charter the physicians entered with great zeal upon the fulfilment of the functions assigned to them. At this period pharmacy had a new and important era inaugurated. At their first meetings the publication of a pharmacopœia engaged their chief attention. To purge the list of the materia medica, and to secure accuracy and uniformity in pharmaceutical preparations then existing, were subjects which forced themselves upon their earliest consideration. When we think how rude and manifold the mass of materials were out of which a selection had to be made, we may form some small idea of the importance of the work, both in the interests of pharmacy and the advancement of medical science, in our own city. After years of labour, the first edition of the 'Edinburgh Pharmacopœia' made its appearance in 1699, which contained nearly nine hundred articles of the materia medica. Here, it is worthy of remark, that during the 172 years which have intervened, we have become acquainted with the medicinal properties of innumerable articles before unknown; yet, the pharmacopœia of today has been considerably reduced. In the first Edinburgh edition we see strong proofs of the prejudice and superstition, which lingered even in the master minds of that age. Amongst the approved pharmaceutical preparations some contained from forty to seventy articles. Notwithstanding all this, the first edition of the 'Edinburgh Pharmacopœia' was an improvement upon any which had previously existed, this superiority being fully maintained in all subsequent editions.

From the middle of the last century till the beginning of the present one, we have no records bearing on pharmacy, which adequately convey to our minds its real condition and working. We have learned something, however, from those who in early life knew how things were conducted in the special calling of a druggist, which designation afterwards came to have the word chemist prefixed. Dating from the above period, we find that there were a number of well-conducted drug shops in the city; amongst them we may mention the following, that of Mr. White's, in the Lawn Market, with whom the late Mr. Duncan, that worthy father in pharmacy, served his apprenticeship; Mr. Moncrieff, North Bridge, to whom the Lords of Session and Baronets of that name are related, and with whom that much-respected and public-spirited citizen the late Baillie M'Farlane served his apprenticeship; then Mr. Manderston, of Rose Street, who by the way once occupied the honourable position of Lord Provost; also, Mr. Milner, who carried on business in the first flat of a house in High Street, and many others too numerous to mention. At this time the system of sending out ordinary medicines and the mode of dispensing prescriptions, was conducted in a different style from that of the present day. However respectable those were who carried on business at that time, their free-and-easy system would seem very strange to us. Drugs were sent out in a style we should be very apt to call careless, having no carefully printed labels, such as we use. Pills were put up in small paper bags; liquids with the name of contents or directions written on paper and tied round the neck of the bottle, and very often without any name at all; while the various alkaloids were known only to a very limited extent, and thought of as a chemical curiosity. The introduction of many of these by Edinburgh chemists, and the changing of many of the absurd modes of nomenclature, inaugurated another new era in pharmacy. I cannot pass from this subject without mentioning the advantages the young pharmacists of to-day enjoy, compared with those in olden times, when the large mortar was their constant companion, and all the gums, resins and roots were powdered in this manner. Had they pills to make, the aloes, gamboge, scammony, etc. had all to be powdered first, there being no pill machine to roll them off, only the old rude tile or small portions of the mass rounded between the thumb and fingers. The wants of the lieges, however, were well attended to, because from seven o'clock in the morning till ten or eleven at night, drug shops were found open, but these days have long since given place to a better system of things, which might even yet be improved.

Though we can now look back and criticize the doings of our ancestors, yet, in many respects, we owe them a debt of gratitude, and, certainly, we should prove unworthy sons of worthy sires, had we not made those advances which have obtained for our city that high and honourable position we now hold in the science of pharmacy.

A NEW SWEET VOLATILE PRINCIPLE FOUND IN THE CAOUTCHOUC OF BORNEO.

BY AIMÉ GIRARD.*

This caoutchouc yields a new saccharine substance—designated by the author as *bornesite*—which is crystalline, very soluble in water, slightly soluble in alcohol, melts at 175° without alteration, and, like dambonite sublimes at 205° with slight decomposition. It does not ferment, neither does it reduce the potassio-tartrate of copper, but acquires the property of reducing this reagent by being boiled for several minutes with water slightly acidulated. Treated with a mixture of sulphuric and nitric acids, it forms a nitrated product, insoluble in water, soluble in alcohol, from which it is deposited in the crystallized state, fusible at 30°–35°, and detonating loudly when struck.

Bornesite has the composition $C_7H_7O_6$, and when heated to 120° in a closed vessel with fuming hydriodic acid, decomposes, like dambonite, into methyl iodide and dambose—

$$\underset{\text{Bornesite.}}{C_7H_7O_6} + HI = CH_3I + 2\ \underset{\text{Dambose.}}{C_3H_6O_3}.$$

Dambonite and dambose have no effect upon polarized light, but bornesite possesses a rotatory power of 32° to the right, or nearly half that of pure cane-sugar under similar circumstances. Dambonite and bornesite may be considered as dambosates of methyl, the combination of two molecules of dambose in bornesite creating in the latter the power of rotating a ray of polarized light.

* Compt. Rend. lxxiii. 426–429, from the *Journal of the Chemical Society*.

THE CHICAGO COLLEGE FUND.

The following is a list of the Committee which has been formed and subscriptions and books promised up to December 8th:—

COMMITTEE.

The President of the Pharmaceutical Society of Great Britain.
The President of the British Pharmaceutical Conference.
Alderman Sir Thomas Dakin, lately Lord Mayor of London and Chairman of the Chicago General Relief Fund.
Thomas Hyde Hills, Esq., Treasurer of the Pharmaceutical Society.
Elias Bremridge, Esq., Secretary of the Pharmaceutical Society.
F. Baden Benger, Esq., Provincial Secretary of the British Pharmaceutical Conference.
Robert Bentley, F.L.S., Professor of Botany and Materia Medica to the Pharmaceutical Society.
Dr. John Attfield, Professor of Practical Chemistry to the Pharmaceutical Society.
The President of the North British Branch of the Pharmaceutical Society, Edinburgh.
John Mackay, Esq., Secretary of the North British Branch of the Pharmaceutical Society, Edinburgh.
C. R. C. Tichborne, Esq., Chemist to the Apothecaries' Hall of Ireland, Dublin.
The President of the Midland Counties Chemists' Association, Birmingham.
The President of the Bradford Chemists' Association.
The President of the Bristol Pharmaceutical Association.
The President of the Colchester Assoc. of Chemists and Druggists.
The President of the Glasgow Chemists and Druggists' Association.
The President of the Halifax and District Chemists and Druggists' Association.
The President of the Hull Chemists' Association.
The President of the Leeds Chemists' Association.
The President of the Liverpool Chemists' Association.
The President of the Manchester Chemists and Druggists' Assoc.
The President of the North Staffordshire Chemists' Association.
The President of the Nottingham and Notts Chemists' Association.
The President of the Sheffield Pharmaceutical and Chemical Association.
The President of the Sunderland Chemists' Association.
The President of the Taunton Chemists' Association.
The Secretary of the Exeter Pharmaceutical Society.
The Chairman of a Sub-Committee of English Students.

S. Chapman Betty, London.
Michael Carteighe, London.
John T. Davenport, London.
William Edwards, London.
Daniel Hanbury, London.
Robert Howden, London.
Joseph Ince, London.
T. N. R. Morson, London.
G. W. Sandford, London.
John Williams, London.
William Albert Sanger, London.
A. Bottle, Dover.
T. B. Groves, Weymouth.
Edward Smith, Torquay.
Francis Sutton, Norwich.
Battley and Watts.
Barron, Squire and Co.
Davy, Yates and Routledge.
Evans, Lescher and Evans.
Hearon, Squire and Francis.
Herrings and Co.
Hodgkinsons, Stead & Treacher.
Horner and Sons.
Savory and Moore.

Executive Sub-Committee.
Thomas Hyde Hills, Michael Carteighe, John Attfield.

Parcels of books, specimens of chemicals, or articles of the materia medica, apparatus, and subscriptions (the whole of which will be expended by the Committee in the purchase of similar contributions) may be sent to Professor ATTFIELD, 17, Bloomsbury Square, London, W.C. Cheques, crossed "London and Westminster Bank," and Post-Office Orders, drawn for "High Holborn," may be made payable to JOHN ATTFIELD.

CONTRIBUTORS AND SUBSCRIBERS.

[Duplicates of books, lecture-specimens, etc., will be dealt with by the Committee, at their discretion, for the general benefit of the Fund, unless instructions to the contrary are forwarded with the parcels. Gentlemen are invited to inquire of Professor ATTFIELD, 17, Bloomsbury Square, London, W.C., as to whether or not copies of the books, etc. which they propose to give have already been contributed.]

MEETING OF STUDENTS.

A Meeting of the students, at 17, Bloomsbury Square, was held on Tuesday, the 5th instant, under the presidency of Mr. Davies, for the purpose of raising a fund among present and recent students of pharmacy throughout the country, to assist their fellow-students in Chicago by providing the College of Pharmacy in that city with books, specimens and apparatus, to replace those lost in the late Fire.

A Committee was chosen to carry out the necessary arrangements. Subscriptions (limited to 10*s.* 6*d.*) or contributions of books, etc. will be thankfully received by the Treasurer, Mr. R. H. Davies, or the Secretary, Mr. W. H. Shenstone, at 17, Bloomsbury Square, W.C., and duly acknowledged in the PHARMACEUTICAL JOURNAL.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 9, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE BRITISH PHARMACOPŒIA.

Professor Redwood has brought before the Society a subject of very considerable interest and importance, and one with which he is especially qualified to deal. We print his paper *in extenso*, and recommend a careful perusal of it to all, whether pharmacists or medical practitioners, who are interested in the improvement of the art of pharmacy. The main question under consideration is, as to the desirability of introducing some alteration into the system of weights and measures at present employed in the prescribing, dispensing and compounding medicines, so as to do away, at least to some extent, with what cannot be regarded other than as a reproach to British pharmacy. We are the possessors of a Pharmacopœia which we are justly proud of, since, having regard to all its features, it is unrivalled in the world for accuracy, conciseness and general practical tone, but, so long as the present anomalous system of quantities remains in use, it can never approach much nearer to completeness.

Professor Redwood has suggested the substitution of proportional or relational numbers for specified weights and measures in the description of processes in the Pharmacopœia; but we cannot help thinking that should his suggestion be adopted, it will be only as a temporary expedient, merely paving the way for the introduction of a more perfect system.

We look forward to the day when a decimal system of some kind will be introduced into all dealings with quantities.

The metric weights and measures are being taught to most boys and girls throughout the country, and as the merits of the system come to be more and more extensively recognized, this instruction will become an essential part of primary school education.

We may, therefore, fairly calculate on this general introduction of decimals some twenty or five-and-twenty years hence. In the meantime, a provisional system, adapted to the purposes of the Pharmacopœia and of pharmacy generally, will be acceptable; and the proposals of Professor Redwood seem likely to be subject to little objection beyond that which attaches to change of any kind. It will be seen from the discussion which ensued upon the reading of the paper, that it received a considerable amount of criticism, most of which was replied to, and to some extent successfully combated by the Professor. In addition to the points raised by the speakers on that occasion, we might suggest in reference to one of the difficulties met with in working out the plan, that the specific gravities of all the liquids employed are known, and, consequently, that it would be no difficult matter to arrange the proportions of ingredients in those preparations in which both solids and liquids occur, so that one part of each solid may be represented by an integral number of parts of the resulting solution or mixture, and yet the amount of liquid to be employed may be expressed in measures. Thus, in an instance quoted in the paper, it is proposed to weigh syrup instead of measuring it. But to avoid the dislike which some practical men might have to this, it would be simply necessary to divide the number of parts by weight by the specific gravity of syrup, and substitute in the formula this *measure* for that *weight*.

In the preparation of a new edition of the Pharmacopœia, however, we do not anticipate for Professor Redwood a task of so much difficulty and labour as in the case of the last. Much experience has been gained and much information elicited from recent discussions. Pharmacists will be doing good service in the cause of their art by continuing to bring forward hints as they crop up in daily business, and a topic is now before them which well deserves their careful consideration.

ILLNESS OF THE PRINCE OF WALES.

The *British Medical Journal* and the *Lancet* publish detailed accounts of the inquiries recently made at Londesborough Lodge and in the neighbourhood of Sandringham Hall. Amongst other things that have been ascertained, indicating very defective sanitary conditions, it appears that the water used for domestic purposes at Sandringham is in a very unsatisfactory state, while at the neighbouring town of Lynn it is described as being no better than the effluent water from a sewage farm. These conditions, which are capable of being so pernicious to health, appear to be referable to that want of any adequate means of dealing with domestic refuse, which is an evil not confined to this district, but prevalent to a serious extent throughout the whole country.

CHICAGO.

A dread calamity, the details of which are known to all the world, has happened to this prosperous and energetic city. It would be idle to describe the terrible misfortune which the press has so faithfully portrayed. Houses desolate, families destitute, and business stopped. In face of this *baptism of fire*, England has to herself proved true, and nobly supported her character for benevolence. Help from innumerable sources has arrived. Pharmacy has not stood aloof, and we refer with unmixed pleasure to the efforts at this moment made, both to express intense sympathy, and to have the honour of sharing in the re-establishment of the Chicago Pharmaceutical Museum and Library. An influential Committee has been formed. We do not generally like a *large* Committee—but this is representative. The presence of so many names is simply an indication of hearty fraternal desire on the part of British Pharmacists to aid America. The list on the Committee includes the names of the Presidents of Pharmaceutical Associations in seventeen of our leading towns, all of whom have offered their active services. The President and leading Officers of the Pharmaceutical Society of Great Britain, together with the Officials of the British Pharmaceutical Conference have promised personal assistance. The chief wholesale druggists, including Sir Thomas Dakin, chairman of the Chicago General Relief Fund, have joined the movement; while better than all, the students have espoused the cause and are engaged in collecting books and subscriptions from apprentices and assistants. Fortunately for Chicago, Professor Attfield has undertaken the burden of executive direction. Parcels of books, museum and lecture-specimens, apparatus and whatever thoughtful kindness can suggest, may safely be intrusted to his care. Cheques and money subscriptions will be devoted to the purchase of books and other contributions. Some donations have been received—at present necessarily few. The Council of the Pharmaceutical Society has voted a bound set of Journals and Indexes. Mr. Joseph Ince has presented fifty-four selected volumes—chiefly foreign—some educational. The students' subscriptions vary from one shilling to ten, others from half-a-guinea to ten guineas. We sincerely hope to see a multitude of small contributions.

Let us learn from this fearful visitation, never to mourn as those without hope. The darkest night *must* have its morning; the blackest cloud cannot for ever shut out the sunshine—there is a resurrection power in this life as also in that to come. Should Chicago rise from its ashes, as it most certainly will, more prosperous than ever; should its citizens emerge from their fearful trial rejoicing as a strong man to run a race; should their hour of sorrow have gained them the sympathy and knit them in the closest bonds of union with another country; there may come a time when thanksgiving may replace distress—then let them call to memory the old, old story, when centuries ago three children passed unharmed through the burning fiery furnace, but there was one whose name was love walking in the midst.

A very pleasant feature of the movement that has been set on foot to assist in restoring the library, museum, and apparatus of the Chicago College of Pharmacy is the warmth with which it has been taken up by the students at Bloomsbury Square. As will be seen upon reference to another column, a meeting was held on Wednesday last, and a committee appointed to make an appeal to all the recent and present pharmaceutical students in the country. We hope the result will be a good one, for we are sure the sympathy shown will be none the less welcome to Chicago students as coming from those who are now, or recently have been, themselves students in England.

Transactions of the Pharmaceutical Society.

MEETING OF COUNCIL.

December 6th, 1871.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

MR. EDWARDS, VICE-PRESIDENT.

Present—Messrs. Atherton, Betty, Bottle, Brown, Carr, Greenish, Groves, Hills, Reynolds, Sandford, Savage, Shaw, Smith, Stoddart, Williams and Woolley.

The minutes of the last meeting were read and confirmed.

The President read a letter from Professor Attfield, asking the assistance of the Society towards reinstating the Chicago College of Chemistry in the matter of books and specimens, which had all been destroyed by the late fire; and suggesting that a complete set of the Pharmaceutical Journal, with indices, would be very acceptable.

It was moved by Mr. Sandford, seconded by Mr. Williams, and carried unanimously, that a complete set of the Journal in volumes, with indices, be presented to the Chicago College.

The Report of the Finance Committee was presented, showing on the General Fund Account a balance in the Treasurer's hands of . . . . £1320. 16*s*. 8*d*.
And submitting for payment sundry accounts amounting to . . . . . . £803. 7*s*. 7*d*.
On the Benevolent Fund Account a balance of . . . . £206. 4*s*. 5*d*.

Resolved—That the Report of the Finance Committee be received and adopted and payments made.

Resolved—That the Report and Recommendations of the Benevolent Fund Committee be received and adopted.

Mr. Shaw said he was somewhat astonished some time ago at hearing it stated that many people were under the impression that the Benevolent Fund was more than equal to the demands upon it. If not so, he should like it to be clearly stated.

The Secretary stated that the annuities granted absorbed more than the interest of the money invested. The Fund was therefore not equal to the demands upon it.

A grant of £10 was made to the widow of a deceased member of the Society. (Second grant.)

Resolved—That a list of subscribers and donors to the Benevolent Fund, accompanied by some account of the objects, and rules under which grants from the Fund are made, should be published for distribution.

The reports of several meetings of the House Committee were read, including an estimate for alterations in the basement of the Society's premises, for the purpose of affording additional accommodation for the Professors of Chemistry and Botany, and the Curator, etc.

Mr. Sandford explained at some length the proposed alterations.

Mr. Williams said the matter had received a good deal of attention from the Committee, and he hoped the report would be adopted. The rooms in question had been taken into possession by the Society, in consequence of greater space being required.

Resolved—That the Report and Proceedings of the House Committee be received and approved.

Resolved—That the Report of the Library, Museum and Laboratory Committee be received, and further estimates for printing the catalogue of books in the library be procured.

The Committee reported that they had accepted Mr. Howlett's estimate for three new mahogany cases and a table for the museum.

Resolved—That the Report and Recommendations of the Parliamentary Committee be received and adopted.

The Committee reported that a case of prosecution which had been commenced against an oilman in London, for selling Oxalic Acid, had been settled by the defendant's paying the penalty of £5 and costs into court.

REPORTS OF THE BOARDS OF EXAMINERS.

November, 1871.

ENGLAND AND WALES.

Examination.	Candidates examined.	Candidates passed.	Candidates failed.
Major	3	2	1
Minor	32	22	10
	35	24	11

Two certificates of examination (one from the College of Preceptors, the other from the University of Cambridge) were presented to, and accepted by, the Board in lieu of the ordinary Preliminary examination.

SCOTLAND.

Examination.	Candidates examined.	Candidates passed.	Candidates failed.
Minor	7	2	5
Modified	3	1	2
	10	3	7

One certificate of examination from the University of Edinburgh was presented, and accepted by the Board in lieu of the ordinary Preliminary examination.

The PRESIDENT presented the following Special Report from the Board of Examiners on the Preliminary examinations:—

Rather more than three years have elapsed since the passing of the Pharmacy Act, 1868, which rendered special examinations, and thereby education, compulsory upon all intending to practise pharmacy.

There are three stages in these examinations; the First or Preliminary for those who at the passing of the Act were apprentices or students, or if serving as assistants were under twenty-one years of age, and for all who may hereafter enter the business; 2ndly, the Minor examination for those who intend taking up only the title of Chemist and Druggist; and 3rdly, the Major, for those who desire to obtain the more honourable one of Pharmaceutical Chemist.

It is to the first of these, or the Preliminary examination, that attention is now directed.

The Bye-Laws of the Pharmaceutical Society, section x., paragraph 12, describe the Preliminary examination as being a test of knowledge of the Latin language, English grammar, composition and arithmetic; and the Board of Examiners has defined the extent to which the examination in each subject shall be carried, so that its exact requirements may be understood; it is as follows:—

"The examination is a written one, and comprises Latin, translation into English of a paragraph from the first book of Cæsar (De Bello Gallico), or a passage from each of the following works:—Pereira's 'Selecta e Præscriptis,' and the last edition (Latin) of the London Pharmacopœia.

"Latin Grammar.

"English Grammar, Composition.

"The first four rules of arithmetic, simple and compound, vulgar fractions and decimals.

"Certificates of having passed the local examinations of the Universities of Oxford, Cambridge, or Durham, the examination of the College of Preceptors, or those of any legally constituted examining body previously approved by the Council, *provided Latin and arithmetic are included in the subjects*, are accepted in lieu of this examination."

The 5th of October, 1869, was the day on which these compulsory examinations were commenced, and nine have been held since that time.

At first, the precise nature of the examination not being fully understood, great success was scarcely to be expected; but, as regards subsequent examinations, the details having been fully explained in public, the Board looked, and surely not without reason, for great improvement.

It is with unfeigned regret that the Board is obliged to confess that replies are no better, while the percentage of failures remains the same.

To alter this state of things, alike painful to the Board and disheartening to the candidates, a review of the past is now contributed.

Taking the numbers of four examinations, it will be found that out of 1101 candidates, 714 passed and 387 failed, an average with a trifle over of 35 per cent. of failures. The highest number of any one of those who passed is found to be 285 out of 300, and the lowest 150, just sufficient to pass. In order that a correct opinion of the cause of failure may be formed, it may be as well to give further particulars.

In each subject it has happened upon several occasions that *no* mark has been given, 3, 4 and 5 have been the lowest numbers given out of 100 for Latin; 5, 8 and 10 for English; and 5, 8 and 10 for Arithmetic. This has occurred more frequently in Latin and English than in Arithmetic. In the four examinations of 1871, 170 candidates obtained less than one-*fourth* the number of marks in Latin, 64 in English, and 44 in Arithmetic; 362 less than *half* in Latin, 275 in English, and 204 in Arithmetic. Thus, it is clearly shown by these numbers that Latin and English, especially Latin, are the stumbling-blocks, and more particularly Latin Grammar, for where that is deficient failure in English Grammar and Composition is to be expected. Arithmetic, though occasionally at fault, cannot be said to be deficient; on the contrary, in many cases, it has been the means of passing candidates, the large number of marks obtained for it making up for the deficiency in the other subjects.

A few samples of free translations from the Latin may be given without offence:—

Quod reliquum est balneo aquoso ad idoneam crassitudinem consume—translated, 'what remains is balneum water to be taken at the same time to-morrow;' quartâ quâque horâ—frequently rendered 'every fourth part of an hour;' lactis vaccini recentis—recent vaccination being calmer; summo mane deglutiendus—to be taken in the morning when the pain is raging; et perfice sicut de syrupo althææ præceptum est—and pass through tow upon syrupus althææ and collect the precipitate; fiat haustus, mane deglutiendus—make a draught to be taken as a jelly; 'coccum' is construed 'cocoa.'

There is evidence here of great want of education, besides guess-work. It would be better to give no answer or no translation than one which is destitute of sense. These examples are from pharmaceutical Latin. Cæsar would furnish equally inaccurate ones. To the questions in grammar the replies are little better as a rule, and often given without the least bearing upon the question. Arithmetic is nearly always well done, but the English composition generally falls deplorably short. The real nature of the subject selected is often misunderstood; there is an absence of style,—a want of accuracy of expression; the illustrations are inapt, the words badly selected and too frequently repeated; the construction of sentences is imperfect, while the connection between one sentence and another is obscure, the spelling is faulty, and the commonest rules of syntax are disregarded.

How can this be altered? Two classes have to be considered, those already in the business and those about to enter it. Of the former there are three divisions, viz. those apprentices of one, two, three, or four years' standing, those who were apprentices when the Act was passed and have since become assistants, and those assistants who neglected registering at the time proper to qualify them for passing the Modified examination. Where elementary education has been neglected the case is difficult; where good, a little systematic persevering study will recover much that has been lost. In either case, they should work with hearty goodwill at the grammar and medical Latin, with which, from their business experience, many of these candidates, under ordinary circumstances, should be well acquainted. For apprentices of any number of years' standing, the early education being good, a little perseverance should set all right; but for those who never have been properly educated, there can be but one course—go to school as soon as possible. But how is this to be accomplished? Employers must aid in this good, this essential work. They can materially assist, and in this way: let some time, either morning or evening, be devoted to study; do not say there is no time, but *make* it.

In every town are to be found teachers obtainable at a moderate cost quite equal to the task. Those gentlemen who, knowing what was passing respecting pharmaceutical education and examinations during the last ten years, yet took apprentices without reference to the amount of education they had received, should help in this great work.

It has been clearly shown that Latin is the first desideratum; let its study be raised to a proper standard, and English will soon follow in the same direction. But, let what may be done, it must be with a will and determination to conquer, and that can only be accomplished by industry, attention and perseverance.

Thus far concerning the apprentices and assistants above alluded to who are actually in the business, having regular business duties to perform, who must, if they are *to commence business as chemists and druggists*, pass the Preliminary examination, and after that, in due course, the Minor.

For them a certain amount of sympathy is felt, and for them masters are solicited to give, as they most conveniently can, time for study and help in carrying it through.

There is the other class which claims at the present time some attention,—the class of future apprentices.

It has lately been put forward that the Preliminary should be passed before indentures of apprenticeship are signed; be it so. The Board is of opinion that this point cannot be too strongly impressed upon parents who may be desirous of placing their sons as apprentices to chemists and druggists or pharmacists, nor upon those gentlemen who undertake the responsibility of having apprentices, for, whatever may have been in the past, it is clear that in the future they should pass either the Preliminary of the Pharmaceutical Society or the Local Examination of one of the Universities or other approved examining body before indentures are signed; this accomplished, a source of anxiety, alike to pupils, parents and masters, would be successfully dealt with, and the apprentice would be able to devote mind and body in acquiring a just and proper knowledge of the business, and becoming in every respect a better and more serviceable apprentice to his master, who, at the same time, would feel that he was instructing one in whose educational attainments he could place confidence.

In drawing up this report—setting forth the candidates' weak points and suggesting a possible way of overcoming their difficulties—but one spirit has pervaded the Board and induced it to take this course,—an honest desire to help those who evidently stand in need of it, and at the same time draw attention to that which is most desirable for the future. Although the Board looks upon the number of failures as large, it is believed that other Examining Boards experience the same results; but the Board is most desirous of seeing a reduction in the number of failures.

It is recommended to present candidates that they should read attentively the remarks made for their guidance which have already been published in the Pharmaceutical Journal, Third Series, No. 50, p. 994.

Mr. Carr said he had been much pleased, on recently trying to negotiate an apprenticeship for a young man in whom he took an interest, to find that his passing the Preliminary examination was insisted upon before the indentures were signed. He hoped this would become general.

Mr. Woolley said he had no doubt that this report would be of great national benefit, in pointing out the deficiencies which existed in education at the present day; but he regretted that the Report had not gone also into the question of the Modified examination.

Mr. Brown was glad Mr. Woolley had called attention to this matter, which he thought was an important omission from an otherwise able and very instructive report.

A long discussion followed, in which Messrs. Stoddart, Smith, Groves, Atherton, Savage, Edwards, Sandford, Reynolds, and the President took part; and it was ultimately understood that if Mr. Brown, or any other gentlemen, would furnish data to work upon, the President would endeavour to draw up a special report on the Modified examination.

It was then resolved that the Report should be published in the Pharmaceutical Journal, and that a separate copy should be sent to each Member of Council and Local Secretary.

Resolved—That the following having passed the Minor Examination be elected Associates of the Society:—

Anderson, Alexander	Elgin.
Breckon, Hugh Scott	Whitby.
Bryden, John	Edinburgh.
Druce, George Claridge	Northampton.
Hanbury, Frederick Janson	London.
Hyne, Harry	Bristol.
Mason, Jonathan	Workington.
Peel, Alfred	Manchester.
Walsh, Albert	Richmond, Surrey.
Warner, George Henry Q.	March.
Wooldridge, George	Birmingham.

Three persons, having paid their subscriptions for the present year, and a nominal fine of one shilling, were restored to membership.

Resolved—That the following having been duly registered as Pharmaceutical Chemists, be respectively granted a diploma stamped with the seal of the Society:—

Hughes, James	Swansea.
Peters, David	Llandilo.

Resolved—That a copy of the Journal be sent regularly as published to the Leicester Chemists' Assistants and Apprentices Association.

EXAMINATIONS IN EDINBURGH.

November 28th, 1871.

Present—Messrs. Aitken, Buchanan, Gilmour, Kemp and Young.

MINOR EXAMINATION.

Seven candidates presented themselves; *five* failed, the following *two* passed, and were declared qualified to be registered as

CHEMISTS AND DRUGGISTS.

Graham, John ....Dumfries.
Bryden, John ....Edinburgh.

The above names are arranged in order of merit.

MODIFIED EXAMINATION.

Three candidates presented themselves; *two* failed, the following passed, and was declared to be duly qualified as a

CHEMIST AND DRUGGIST.

McAdam, Robert ....Glasgow.

PRELIMINARY EXAMINATION.

A certificate was received from the undermentioned in lieu of the Society's Examination.

McNaught, Andrew ....Belfast.

(*Certificate of the University of Edinburgh.*)

PHARMACEUTICAL MEETING.

Wednesday, December 6th, 1871.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

The following Donations to the Library and Museum were announced, and the thanks of the Society were voted to the donors:—

Catalogue of Scientific Papers (1800-1863), Vol. V.: from the Royal Society,—Life and Works of Cavendish: from Professor Redwood,—New Remedies; a Quarterly Retrospect of Therapeutics, etc.: from Messrs. W. Wood and Co., New York,—Fine crystallized specimens of Cyanide of Potassium and Permanganate of Potassium: presented by Messrs. Hopkin and Williams,—Bark of *Cinchona calisaya* grown in Java, and infected by Mycelium; five specimens of *C. officinalis* bark, from different localities; Roots of *C. succirubra* and *C. officinalis*, grown in India; Section of a Stem of *C. officinalis* grown in India; Section of a Stem of *C. succirubra*, grown in South America (the whole of the specimens being in illustration of Mr. Howard's paper read at the last meeting): presented by Mr. J. E. Howard, F.L.S.,—Bark of *Rhamnus Frangula*, the Black Alder of Northern Europe: presented by Mr. H. C. Baildon,—a sample of Zanzibar Aloes: presented by Mr. F. J. Hanbury,—Bark of the *Cundurango*, or Eagle Vine: presented by Mr. Rowland Cox,—sample of very fine Asbestos: presented by Mr. Slipper,—German Herb Knife for coarse comminution: presented by Mr. E. T. Agnew.

Dr. TILDEN exhibited to the meeting a cabinet for holding labels on the dispensing-counter, which had been invented by Mr. Shephard, Pharmaceutical Chemist, of All Saints' Road, Westbourne Park, a former student in the institution. He said it was well known that labels often got into a dreadful state of confusion. The principle of the cabinet in question was very simple. Each compartment was fixed on a pivot, and when pulled forward the front part of the case came down and exposed the labels, so that they could be easily removed. When a label had been taken out the door would fall back, in consequence of being weighted at the back. The arrangement was in fact self-acting, and it appeared to him (Dr. Tilden) a very capital one. The cabinet before the meeting was only a model.

Mr. ALLCHIN asked whether the cabinet would be applicable to the general labels used by chemists and druggists?

Dr. TILDEN considered that it would be applicable to any labels, and even to slips of papers for powders.

Mr. HILLS said that he should think it was a very useful arrangement. It was quite new to him, and he thought it might be turned to account in its present form, or perhaps some further improvements could be made in it.

Mr. BLAND asked whether the cabinet was intended to stand in a vertical position? It seemed to him that if it was, that would be a very serious objection, as there were three or four hundred different kinds of labels in use, and the cabinet would occupy an inconvenient amount of space.

Dr. TILDEN said that even the small model before the meeting would hold a very large number of labels.

Professor ATTFIELD considered that the position of the cabinet would be an advantage rather than otherwise, as in most shops there was some amount of vertical unoccupied space at the backs of doors, showcases and elsewhere.

The PRESIDENT then invited a discussion on the paper by Mr. Greenish, on "Pharmacy in North Germany," read at the last meeting.

Professor ATTFIELD said he should like to ask Mr. Greenish whether, in the course of his visit, he noticed any general organization throughout Germany for the representation of pharmacy? The chemistry of Germany was unquestionable. They had taken a very leading position in that country in matters relating to pure chemistry, and also to the application of chemistry to the arts generally, but he was unaware whether there was anything which corresponded to the Pharmaceutical Society here in Great Britain, or to the Pharmaceutical Conference which met once a year in the provinces.

Mr. GREENISH replied that he thought he might say positively that there was nothing of that kind in North Germany, but he believed that now that Prussia had absorbed the minor States, and there was to be one German Pharmacopœia, it was probable there would be more union among the pharmacists of North Germany. There was a Pharmaceutical Society at Berlin, but comparatively few chemists belonged to it, and its meetings were more for trade purposes than for scientific purposes.

Mr. WALTER HILLS said that during a visit of a few weeks to Germany he attended several lectures on chemistry by Professor Hofmann, and he was surprised to find so great a number of students present. The theatre was intended for 220 persons, and there were present, generally speaking, about 250, 30 of whom were standing. Among other novelties there were two ladies, one of whom was a Russian apothecary. The laboratory also was quite full, and he believed that in order to obtain a bench it was necessary to bespeak it before the commencement of the session. Professor Hofmann told him that he had 90 working students in the laboratory at Berlin. As regarded anything approaching to a Pharmaceutical Society in Berlin he believed, as Mr. Greenish had said, that the meetings of that Association were more for trade than scientific purposes. He could speak very highly of the lectures which were delivered in Berlin. They lasted for an hour and a half, commencing about half-past nine in the morning. In reply to a question, Mr. Walter Hills stated that the lectures were for general chemical students and not for pharmaceutical students only. The lectures were paid for, but strangers were admitted to single lectures as a privilege.

The PRESIDENT said there were several points in Mr. Greenish's paper which would furnish material for another very long paper. Among these were the fly-labels; no competition in Germany; the fixed price to rich and poor; the difficulty of getting apprentices and assistants; the necessity of every apprentice having passed a preliminary examination before he entered the trade of chemist and druggist; and the very honourable light in which the Germans held the Pharmaceutical Society. Those were a few points, but there were many more which might very well be extended into another good paper in the hands of some contributor. He should like to see such a production in the columns of the Journal.

The PRESIDENT then called upon Professor REDWOOD to read a paper on "The Substitution of Proportional or

Relational Numbers for Specified Weights and Measures in the Description of Processes in the Pharmacopœia."

[This paper is printed at p. 461, and gave rise to the following discusssion:—]

The President said that the subject was a very important one, upon which he was not at present prepared to offer any remarks. From what Professor Redwood had told them, it was clear that to his mind an alteration might be accomplished without any great difficulty. He (the President) was inclined to abide by the decision of Professor Redwood until he had an opportunity of turning the matter over in his own mind.

Dr. Tilden said that Professor Redwood had had so much experience, and had expended so much thought upon the construction of the Pharmacopœia, that he felt a little hesitation in offering any remarks, but if he might make a slight suggestion, he should recommend the adoption of the name "*pond*" for parts by weight, and "*vol*" for parts by measure. Each of these units must of course have a definite value, which must be distinctly understood. He should further suggest that the weight of a "*pond*" should be a decigram, which was about a grain and a half, and of course a "*vol*" would be a volume corresponding to that weight. He believed that the application of a name, specially employed for this purpose, would be likely to facilitate the use of the system. He protested against the introduction of any more chemical processes into the Pharmacopœia, inasmuch as in the majority of cases they were not followed by manufacturers, and it was well known that pharmacists were not in the habit of making chemical preparations for themselves. It was, moreover, an objection that, in the case of the alkaloids, the process must vary in detail on every occasion in which it was employed. Take the special case, for instance, of digitalin, which had been alluded to, or aconitia, or he might allude to aloes, with which he was specially familiar. The extraction of the crystalline principles from those substances would be effected by processes which would vary according to the quality of the crude drug operated upon, and other circumstances. It was well known that sometimes aconite, for instance, would yield a far larger quantity of aconitia than at others; and he believed that any minute details such as were set out for all the processes of the alkaloids especially, in the Pharmacopœia, were almost superfluous, simply because they were not applicable in every case. Then, in the case of chemical preparations he was not sure whether it was a valid objection; but it was an objection to a certain extent to set out the ingredients one after another, as in the case of chloroform, which was represented in the paper. He knew an instance of a student going to work to make chlorate of potash, and getting the biggest pan he could obtain, and putting into it the lime, the carbonate of potash, the manganese, and then pouring on it the hydrochloric acid. There was a constant tendency to that sort of thing. People making such preparations were very apt to look through the ingredients, weigh them out, and put them all together without reading through the processes. Chemical manufacturers, as he said before, followed their own processes, which they had learnt from experience, and which, on that very account, were superior to any which could be given to them.

Mr. Groves said they all were much indebted to Professor Redwood for bringing this subject forward. No doubt there was room for improvement in the mode of stating the quantities in Pharmacopœial processes, but, with all due deference to Professor Redwood, he thought the proposed plan not sufficiently simple. He should prefer expressing proportions of fluids in minims or fluid ounces, the whole compound equalling 1000 of such. He should much regret adopting any system that would tend to necessitate the weighing instead of measuring fluid in dispensing prescriptions. The loss of time by such an arrangement would be something enormous, and become a very serious objection. In cases where solids were dissolved in liquids, the expression would be x grains in 1000 minims. In mixtures of solids the grain would be the sole unit, and 1000 grains the weight of the whole. Could every item be brought to the centesimal standard, it would of course very much facilitate the work of prescribers. He did not see the advantage of introducing grain-measures into the Pharmacopœia, and should prefer sticking to the old and well-understood minims and ounces. He offered these few hasty remarks with every sense of their imperfection, and without any intention of committing himself to them definitively.

Mr. Bland said he had some difficulty in saying anything upon a subject like this, especially after Professor Redwood, but it seemed to him that some of the difficulties which he had shadowed forth as to the present state of the formulæ in the Pharmacopœia would not be removed or simplified by the alterations proposed. Like very many other persons who were advancing in life, he began to feel more and more a tendency towards a sort of conservative feeling, and he thought there was nothing so bad or so inconvenient for them as pharmacists as to be continually changing. If alterations in the direction suggested by Professor Redwood were to be made it must mean nothing more or less than this, that they must eventually adopt the metric system altogether. So long as the weights of solid substances and the measures of liquids were divided on a totally different system, it would be utterly impossible so to arrange the parts and measures as to avoid confusion with regard to the quantities. He would take as an instance the proposed formula for spirit of camphor. It had been stated camphor 1 part, rectified spirit 9 measures. Well, suppose he was going to make spirit of camphor. He should at once take 4 ounces of camphor and 36 fluid ounces of rectified spirit. But some of his friends whom he saw around him in the wholesale trade would think that was a very peddling little operation, and would be very sorry to lose their time in compounding such a quantity as that. How would they compound it then? They would make perhaps at least eight times that quantity of spirit of camphor, and they would say, "I am to take 1 part of camphor. What does a part mean?" If they took the part to mean a pound, they must immediately alter the relation of the rectified spirit, seeing that the measures by which the spirit was measured were component parts of a pint in the small quantity which he supposed was intended in the Pharmacopœia. The camphor would be estimated by ounces, and the rectified spirit also by ounces. He confessed he looked back with something like regret to the old pint of 16 fluid ounces and the old ounce of 480 grains. Whatever might be their inconveniences and defects, they had the advantage that they were divisible by a large number of factors, and did in that way very much facilitate calculation when proportions of ingredients were required to be used differing from the quantities set forth in the Pharmacopœia.

Mr. Williams said that the formulæ of the Pharmacopœia were intended for retail use, and the large manufacturers might be left to themselves. He certainly thought that the plan suggested by Professor Redwood was an exceedingly good one. It was easier for the mind to grasp the idea of measures or parts by weight as suggested by Professor Redwood than proportional parts of a thousand as suggested by Mr. Groves.

Professor Attfield said he could sympathize with the remarks made by a gentleman who seemed to represent conservative interests, but at the same time he thought there was a good deal to be said on the other side of the question. He himself belonged, in matters of this kind, to a very strongly conservative party,—to a party much older than the conservative party which was represented by Mr. Bland, a party which had been in the habit for many generations, for many centuries, of counting by tens, probably because every member of the race had ten fingers and ten toes. Now it seemed to him, in all these discussions about weights and measures, both of quantity and length and coin, we were coming back to what was the simplest plan, and that by means of which we could measure, weigh and calculate with the smallest amount of trouble; and that was the decimal plan. Whether that decimal plan would prove to be the metric or any other modification he did not know, and he did not very much care: but in the conviction that it was a decimal method which we were all drifting to, whether we liked it or whether we did not like it, he thought that the proposal of Professor Redwood was not only an important step, but the step which the time demanded in that direction. He himself believed that we should eventually come to the metric system of weights and measures, because it was that decimal form of measures and weights which had been adopted by the leading countries of Europe. But we in England were all strongly conservative, and we might not like to employ the Greek and Latin terms which were involved in the metric system of weights and measures; and it might be a generation, and perhaps more, before we should arrive at any desirable position in the matter. But he could conceive no better method of reaching the goal to which we seem to be drifting than by the adoption of this method of Professor Redwood. With regard to what Dr. Tilden had said, he could strongly sympathize with him. He also had found that students, who knew necessarily nothing of chemistry,—who came, in fact, to that institution and others to learn chemistry,—had always had an impression that a formula meant a catalogue of substances to be mixed together, *secundum artem.* He had met with the difficulty which had been alluded to, but it seemed to him that that difficulty was not any argument in favour of the abolition altogether of chemical processes from the Pharmacopœia, but rather one for the recasting of the language of the Pharmacopœia in reference to chemical processes, for the educational value of the latter was considerable. He should be disposed, with a view of meeting that difficulty, to retain the form of language used in describing Galenical preparations, and to somewhat alter the arrangement of paragraphs and sentences in those formulæ relating to chemical preparations, so that there might be an obvious difference to the eye of those who knew nothing of chemistry, between a Galenical formula and a collection of weights and measures of substances which are to be put together, and which, when put together, will act chemically upon each other.

Mr. Allchin said that it appeared to him that the proposition made by Professor Redwood was open to no objection whatever; but, with regard to the introduction of the metric system, there were many difficulties to be overcome. It was not a question for pharmaceutists only, but for the whole medical profession. Men who had been to college, and just passed their examination, did not expect to have to go to school again. There would be a strong opposition to any attempt to introduce the decimal system into the Pharmacopœia.

Mr. Lenton said that, with regard to the present grain and minim, they were really founded on nothing at all. There was no standard for them. But the metric unit was pretty much what Thomas Carlyle would call one of the "eternal verities." He (Mr. Lenton) believed that our calculations would and must at last come to the metric system. Students would find that they could divide by ten more easily than by any other numbers, and he believed that students would offer no opposition to the metric system on the ground of difficulty.

Professor Redwood said that, although unwilling to detain the meeting from the hearing of other papers, yet out of respect for the speakers he must say a few words in reply. He was very much obliged to Dr. Tilden for his suggestion as to the substitution of the two words "*pond*" and "*vol*" for part and measure; but he (Professor Redwood) thought that words already in use in the sense in which he proposed to adopt them, were preferable to new terms. Some persons might be puzzled by "*pond*" and "*vol*" and might think that they were some special quantities instead of terms applicable to any quantities. He entirely agreed with what Dr. Tilden had said with respect to chemical processes in the Pharmacopœia, and he had opposed the introduction of some of those given in the last edition. Wherever a perfectly clear definition could be given of a chemical product, he believed that definition would be quite sufficient. He thought, however, that Dr. Tilden had fixed upon an unfortunate illustration in stating his objection to giving the chemical processes. He had mentioned digitalin, which was precisely a case in which there would be a difficulty in omitting the process. In that instance the process must be stated in order to define what the digitalin was. There were two or three kinds of the substance, varying according to the processes by which it was prepared, and the digitalin of the Pharmacopœia was not the simplest form of the active principle of digitalis. In that case, therefore, the process must be described, as the digitalin could not otherwise be defined. Mr. Groves had objected to the weighing of fluids. Well, it was not part of his (the Professor's) method that they should change from the measuring to the weighing of fluids, except in a very few special cases. He admitted that the habits of our British pharmaceutists were such as would not exactly agree with having to weigh in every case. The method of giving proportional numbers, as adopted in Continental Pharmacopœias, was made very simple if everything was weighed. All that was needed was to give numbers which might represent grams or any other equal weight, the same denomination being applied throughout. He thought, however, that Mr. Groves would find that there was only a small number of cases (not a dozen altogether) in which they would have to weigh liquids according to his (Professor Redwood's) proposition. He could not help thinking that there was a manifest advantage in weighing the syrup in confection of opium, and having a product in which the active constituents bore a definite relation to the whole. He was much obliged to Mr. Groves for suggesting, with reference to spirit of camphor, that which certainly had not occurred to him (Professor Redwood) before; and he certainly concurred that spirit of camphor should be made of such a volume that the camphor should bear a definite relation to the whole product, either weight to measure, or weight to weight. He must here, however, say in his own justification, that his present object had rather been to elicit, from practical men, an opinion as to how far it was desirable to attempt to carry out in the completest manner a method which he had described only in its broad features. It would involve, if applied to the Pharmacopœia, a great amount of calculation and reworking of all the old processes; and he had not thought it necessary or judicious to enter upon a work of that description until he was able to ascertain how far such a method was likely to be received with favour and permanently adopted. Otherwise, he might work for a year or two in the reconstruction of formulæ according to the new method, and then find at last that the method was not approved of and that all the time occupied by his calculations had been thrown away. There were many improvements which might be made in simplifying the processes, but what he had done was chiefly to apply his method to the processes of the Pharmacopœia as he found them. Some of the other points which had been raised had been already answered in the course of the discussion.

A paper by Mr. T. Miller, of Sheffield, "On a Method for the Estimation of Morphia in Opium," was read by Professor Attfield.

[This paper is printed at p. 465, and gave rise to the following discussion:—]

The President said that this paper was a very interesting one, and the results given in the table certainly appeared to be rather satisfactory. The only question which arose in his mind was as to the use of the eye of the operator in arriving at a conclusion. Different operators might arrive at different conclusions on the same specimen, and some people could not distinguish colours at all.

Professor ATTFIELD said Mr. Miller did depend upon the colour of his solution of iodine in disulphide of carbon; but his experiments showed that his eye could be trusted, for he had performed other experiments in which he did not trust his eye, but estimated the iodine by another method. Moreover, Mr. Miller referred to the possibility of any operator not being able to distinguish accurately the differences in nearly similar shades of colour, and showed that this difficulty could be controlled, if an operator wished to control it, by another method,—Dupré's method. It occurred to him that, if there was any objection to this process of Mr. Miller, it was not exactly the usual one against volumetric methods, viz. that it would occupy far more time to prepare standard solutions than to make a gravimetric determination, because, although that was a very tangible and valid objection in many cases, still operators had frequently to examine a great number of samples, and then the volumetric method was immensely useful, and saved an enormous amount of time. That was not an objection which seemed to him to attach to Mr. Miller's method; but it was this, that this process most peculiarly seemed to depend more than most volumetric processes on the observances of a great number of conditions, and, therefore, it was not likely to be so popular a process as when a volumetric method depended upon some definite constant reaction. However, he thought the Society was greatly indebted to Mr. Miller for the labour which he had undergone in carrying out this investigation, because there were many other points of view from which it was excessively interesting. The nature of the reaction was peculiarly so. He believed that many years ago the reaction of iodic acid on morphia was investigated, but without any definite results. There was enough done, however, to show that by careful working the nature of this reaction might probably be made out; and if this paper of Mr. Miller's should lead him, or induce any other gentleman, to continue the investigation and ascertain what the reaction actually was between iodic acid and morphia, and the exact conditions under which the reaction occurred, then his process might have a considerable value, for he supposed every one who had attempted to estimate the amount of morphia in opium (at all events any number of times) would have found a very great deal of difficulty, and would hail with pleasure any suggestion which would be likely to economize the time, and enable him to get at better results than he could now obtain by the current processes.

Mr. WILLIAMS said he thought the paper was a very important and interesting one. He wanted to ask this question:—Was he to understand that the iodic acid solution was merely made from 200 grains of iodine mixed with six ounces of water, after a very complicated chemical process, in which the iodate of barium was thrown down and washed, and afterwards decomposed? Was there no other way of standardizing that solution?

Professor ATTFIELD: Yes, by a weighed quantity of morphia.

Mr. WILLIAMS said it seemed to him that it should be standardized. He thought there were the germs of a good process, but it required working out still more; and the point with regard to the standard character of the iodic solution was one that must be decided in a very different way from the process given in the paper.

Professor REDWOOD said that one objection which seemed to attach to this process, and one which Mr. Miller had, in fact, himself indicated in his first experiments, was that the iodine first set free was soon lost to a great extent. Mr. Miller had attempted to overcome that difficulty, and probably he had succeeded, in some degree, by removing the iodine from contact with the organic matter in the solution as quickly as possible.

Professor ATTFIELD: In half a minute.

Professor REDWOOD said that, although it might be removed in half a minute, still there was a race between two reactions. They knew what iodine as well as chlorine would do when brought into contact with organic substances. There was a loss of free iodine, and the extent could not be known, and the whole of the iodine did not at last contribute to the colour. That seemed to be a fundamental objection; and any of those persons who had had experience in testing for the presence of starch in complex organic liquids by means of iodine, must have met with frequent cases in which they could get no reaction at all, the iodine being disposed of as free iodine before even the colour-test of starch could be produced. He had met with cases of that description in testing for the presence of starch in sarsaparilla solutions, and other complex organic liquids. The reason why Mr. Miller could not at first get any results that were reliable was that the iodine was left in the presence of organic matter, and was so disposed of, and hence did not contribute to the colour. This objection to the process of Mr. Miller might not be so serious as it appeared; but he (Professor Redwood) confessed that he should feel greater reliance on a direct method by which the morphia was got out, so that it could be weighed and tested, than on an indirect method of this description, more especially when it was considered that although the object of the process now described was to economize time and to save trouble, it seemed to be a more complicated process than that given in the Pharmacopœia. He might say that he had himself been working upon this subject for a considerable time, and had made a great number of determinations of the quantity of morphia in opium, by the several known processes, including that described in the Pharmacopœia. He should hail with great satisfaction a good volumetrical method of estimating morphia, but he feared that the process of Mr. Miller was rather an untrustworthy one. He (Professor Redwood) had arrived at the conclusion that the process given in the Pharmacopœia was the best. He admitted with Mr. Miller that the Pharmacopœia process was somewhat tedious, but he thought that the details of it might be modified so as to render it less tedious. The time occupied was taken up chiefly in percolating and exhausting the opium by percolation. The process might perhaps be improved in that respect.

Mr. ALLCHIN said that perhaps he might be allowed to describe a process which he had followed for some years in the estimation of morphia in opium. It consisted merely of exhausting the opium with water, and evaporating down the aqueous solution. He took 100 grains, and evaporated the solution to an ounce and a half. He then dissolved a drachm of sesquicarbonate of ammonia, and mixed the two solutions; collected the precipitate on a filter, and washed it until the solution ceased to pass through coloured. He found that opium gave about 21·5 grains of impure morphia. He was aware that in some cases this would not be a proper way of estimating opium, but it would be very easy for those who prepare opium to introduce a little chloride of calcium to procure a corresponding precipitate. He believed, however, it was a very correct way of estimation. At the time opium was dear he obtained various specimens, and tested them by this process, and, curiously enough, each result corresponded with the price of the opium, proving to him that there was a very correct estimate in the market of the value of the opium. If the sample was likely to contain lime or some salt, it would be necessary to carry the process one step further; perhaps liquor potassæ might be used to dissolve out the alkaloid, leaving the inorganic salt behind.

Mr. GROVES said that there was no doubt that Professor

Redwood had hit the blot in this paper. In the presence of morphia and other organic principles, the iodine would soon displace hydrogen and become invisible. The action of iodine on narceia was very peculiar. They were aware of the dark blue colour obtained by adding to it free iodine. On warming the liquid the colour disappears temporarily, and when it reappears is of much diminished intensity. Fresh iodine restores the colour. This series of reactions can be continued until iodine no longer produces a blue but a brown colour, like that of the periodides of the alkaloids generally. He could not help, however, expressing his admiration of Mr. Miller's paper, whilst entertaining the opinion that it was not truly practical. He should be surprised if such a complicated process could be got through in two hours and a half.

Professor Redwood said it certainly could not be accomplished in that time if the drying were included.

Mr. Groves, continuing, said that the processes for the estimation of morphia in opium were very numerous. He met with a new one every six months or so, but they all failed in one particular, viz. the long time required for carrying out the operation. He had thought of trying if Mohr's method might not be modified, so as to be made alkalimetrical, and at the same time sufficiently accurate for trade purposes. The mixture of lime and opium is of such a texture as to be very readily exhausted with water; and if the amount of percolate were made a fixed quantity, he thought that the addition of a standard acid would indicate the quantity of the lime compound present, from which the quantity of morphia could be calculated, with, of course, certain corrections, such as experiment alone would point out. The rapidity obtainable by some such method would seem to justify a trial or two.

Dr. Tilden said that he was under the impression that iodic acid had been quite condemned as a reagent for morphia, simply because the reaction was not definite, and because iodic acid was similarly decomposed by other substances. They all knew what a complex body opium was. There were at least twenty-five different alkaloids described as having been derived from opium, and until the reaction of every one of these had been ascertained, he should question the accuracy of such a process. That objection would apply to any volumetric process for morphia, because it would be necessary to ascertain the reaction of the reagent on every one of those organic principles before the operator could be sure that the reaction he was examining was due entirely to morphia.

Professor Attfield remarked that another important point, in addition to the action of iodic acid on the alkaloids of opium, was the action of the iodine that was set free on these alkaloids. Dr. Tilden had worked upon the question of the action of iodine on the alkaloids of opium and the formation of the periodides, and perhaps he could say something on that subject, confirmatory or otherwise, of what Mr. Miller had stated.

Dr. Tilden said that iodine combined with nearly all the organic bases, decomposing one portion of them to form hydriodic acid, and forming compounds which in most cases seemed to be tri-iodides, consisting of a molecule of the alkaloid *plus* a molecule of hydriodic acid *plus* two atoms of iodine. Those compounds were perfectly definite and crystallizable substances, so that a certain portion of iodine might be disposed of in that way. It was possible that might account for the disappearance of some of the iodine. Disulphide of carbon would not be capable of removing iodine from such a compound, and so would not become coloured. The compounds were not soluble in the disulphide.

Professor Attfield said that Mr. Miller's remarks were confirmatory of those now made by Dr. Tilden, with one exception. Mr. Miller said that iodine water, when added to a slightly acid solution of papaverin, produced some sort of compound from which disulphide of carbon abstracted the iodine and liberated the papaverin. That seemed to be an exception. It seemed to be the general rule that disulphide of carbon did not attack these combinations.

The President gave a summary of the contents of a paper written by himself on "The Syrup and Resin of Tolu, and Tincture of Cinnamon." [This paper is printed at p. 467.]

The meeting was adjourned to the 7th of February, 1872.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Fourth General Meeting of the Society was held on November 23rd; the President, Mr. E. Davies, F.C.S., in the chair.

The following donations were announced:—Current numbers of the 'Pharmaceutical Journal;' the 'Journal of the Liverpool Polytechnic Society;' an 'Abstract of the Proceedings of the Liverpool Geological Society, 1870–71;' the 'New York Druggists' Circular;' and 'A Metric System of Arithmetic.'

Specimens of alum, illustrating Spence's process of manufacture, were presented to the Museum by Mr. Williams.

Mr. Abraham said that there had been lately in the Pharmaceutical Journal a good deal of correspondence respecting tincture presses, and as the subject seemed to have considerable interest, he would mention his experience with respect to them. He had for eighteen years used an hydraulic press made by Mr. Coffey, and found that it remained as good as new. The diameter of the ram was $4\frac{2}{16}$-inch, of the piston of the pump $\frac{7}{16}$-inch, the area would therefore be as 36 to 1, and the lever would multiply the power twelve times. Altogether, the power of the hand would be multiplied 432 times; and, supposing the pressure of the hand to be 50 pounds, the press would raise about 10 tons. Messrs. Hayward, Tyler and Co. had introduced a compound press which was calculated to exert a pressure twice as great as this. But he did not find that the price of the hydraulic press had been reduced since he bought his. On the other hand, Mr. Staples had described a screw press, which was said to exert pressures as great as these. He did not question the possibility of this, but his preference for the hydraulic press was founded on the facility with which a moderate, gradually rising to a great, pressure could be applied. But if Mr. Staples's press would bear the assumed pressure, any one who would look at the figures of it and of Messrs. Hayward's, as well as of other hydraulic presses, would see that the strength of the latter was greatly in excess of the necessities of the case.

In answer to observations by the Chairman and others, Mr. Abraham said that the form adopted by Messrs. Hayward involved a short ram which necessitated a screw over it, and added to the cost. The force that all who had used the screw press knew to be required to reverse the movement, indicated the force which had to be overcome before any useful pressure could be applied by means of it. He did not think that the leakage ascribed to the hydraulic press interfered with its application as a tincture press, because whatever press was used the tincture would soon cease to flow unless the pressure was renewed. He thought the hydraulic press would invariably be preferred were the price the same, and hoped that cheaper forms might be devised.

Mr. A. H. Mason, F.C.S., showed a specimen of Cundurango.

Dr. Charles Symes then read a paper, entitled "Observations on Practical Pharmacy."

A discussion on the subject of the paper followed, in which the President, Messrs. Abraham, Blood, Redford, Tanner and Armstrong took part.

A vote of thanks to Dr. Symes for his interesting paper was proposed, and unanimously carried.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Fifth Meeting of the Session of this Association was held in the West Hall, Anderson's University, 204, George Street, on the evening of Wednesday, November 29th; the President, Mr. THOMAS DAVISON, occupied the chair, and there was a good attendance.

After the usual preliminary business, in course of which several new members were enrolled, the CHAIRMAN introduced Mr. M. H. Cochrane, F.C.S., who delivered the following lecture on "Coal and its Products."

Mr. Cochrane was frequently applauded in the course of his lecture, several of the beautiful experiments he performed being much admired; and at the close, on the motion of the CHAIRMAN, he was awarded a very hearty vote of thanks.

A short discussion then took place on the present aspect of the early-closing movement, but as the committee appointed at a recent meeting had not been able as yet to give in a final report, it was adjourned till next meeting.

On Wednesday evening, December 13th, Mr. J. L. Macmillan will read a paper on "Adulteration of Drugs."

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

THE CHICAGO COLLEGE FUND.

Sir,—Your leading article of last week has sketched the great loss sustained by pharmacists at Chicago, in the destruction of their college by fire. May I propose that a special appeal be made to pharmaceutical students throughout the kingdom, to assist our fellow-students on the other side of the Atlantic, by subscribing towards the re-furnishing of their college?

Pharmaceutical students, as a rule, are not rich, but they are kind-hearted, and would gladly help those who have been deprived of the means of continuing their studies. A "Students' Subscription List" has been opened here; and if a similar plan were adopted by the students in other schools and classes, and if students working at home would also forward contributions, either to Professor Attfield or the Treasurer or Secretary of our Students' Fund, the result could but be highly satisfactory from all points of view.

R. W. HOUGHTON.

17, *Bloomsbury Square, London, Dec. 4th*, 1871.

THE BETTS SUITS.

Sir,—It may interest some of your readers to be informed that the suit of *Betts* v. *Rimmel* was allowed to remain in abeyance until the result of the plaintiff's appeal in *Betts* v. *Willmott* was known; that the plaintiff has lately been pressed to dispose of the case; and that he has now abandoned his suit by presenting the common petition to dismiss his bill with costs to be paid by him.

FLUX AND CO.

Leadenhall Street, London, 5th Dec. 1871.

THE PRELIMINARY EXAMINATION.

Sir,—I have noticed a comment from W. H. J. in Saturday's Journal, in which, after quoting from a provincial paper, he proceeds to say, "I presume this was inserted as a cheap way of advertising the establishment to which this learned gentleman belongs." It would have been well had W. H. J.'s presumption not run so far. Lord Byron's lines,

> "A man must serve his time to every trade,
> Save censure—critics all are ready made,"

would certainly apply here. Happening to be in that particular neighbourhood about a fortnight since, it was a great pleasure to spend an evening with my old master, who then told me of this young fellow, an improver, having sent this communication to the paper, and expressed himself as very disgusted with the fact, dwelling especially upon the term with facility.

Had W. H. J. been as fully informed as I am, he might possibly have written in a different tone. As an old apprentice of an honourable man, and one who in former years had the especial good fortune to turn out many good business men, I do feel annoyed to think that he should be subjected to such a gratuitous insult, and do hope, that now from a perfectly disinterested party the true facts have come, he may, to a man advancing in years, if on that score alone, offer an apology for that which I feel sure must have caused some pain and annoyance.

November 20th, 1871. VERITAS.

[*** We have also received an anonymous letter, under the initials "*N. B.*," and purporting to be written by the person referred to in the paragraph. As an anonymous communication we cannot publish this letter, and moreover it seems impossible that it could have been written by any one who had passed the Preliminary examination.—ED. PHARM. JOURN.]

DEATH FROM AN OVERDOSE OF HYDRATE OF CHLORAL.

Sir,—In your report of the above case in last week's Journal, Mr. Cox says, "If sal volatile were taken at the same time as chloral hydrate, it would increase the action of the latter." I scarcely think that it would do so, as alkalies decompose hydrate of chloral. If we can increase the power of the latter by sp. ammon. co., why not prescribe them conjointly? the one being so much cheaper than the other. But I fear Mr. Cox's theory is a fallacious one, and will not be borne out in practice.

Brecon. B. S.

"A SWINDLE."

Sir,—A "gent," calling himself my brother, yesterday ordered in my name some three pounds' worth of goods of Messrs. Bourne and Taylor, Castle Street, Holborn,—of course taking a portion of them with him, and requesting the remainder to be sent on to me in the evening. Of course, also, I know nothing at all about it.

Unfortunately, Messrs. B. and T. were not aware that my brother, who is well known to them as an old customer, is an only brother.

The "gent" is about 5 ft. 3 in. high, and dark.

The trick may be repeated, and I will therefore ask you to give it publicity. ALFRED P. BAKER.

33, *Norfolk Terrace, Bayswater, 5th Dec.* 1871.

G. C. Druce.—(1.) Either may be adopted, according to the preference of the operator. (2.) We do not undertake to recommend particular makers: consult a Directory. (3.) Yes; apply to the Secretary. (4.) Trübner, Paternoster Row. (5.) About 4*s.* 6*d.*

"*An Assistant.*"—(1.) We do not know of any such books. (2.) Beasley's Druggists' Receipt-Book (Churchill), and Blaine's 'Outlines of the Veterinary Art.'

Dalrymple v. *Lakin.*—We have received a letter from Mr. Dalrymple, in which he states that our report of the above case was "incorrect in several very important points." We are obliged to him for the trouble he has taken in writing and forwarding another report of the case; but on comparing that with our own report in last week's Journal, we fail to see any difference which materially affects the general aspect of the case. We are compelled to defer the publication of an abstract of the decision in the case until next week.

P. Childs (Newbury).—Your letter conveys an individual imputation. We have therefore referred to the firm in question.

We are compelled by want of space to defer the publication of several communications.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. G. Mee, Dr. Lauder Lindsay, Mr. J. Mackenzie, Mr. C. R. Beckett (Melbourne), Professor Tuson, Mr. S. T. Severs, Mr. J. Bienvenu, Mr. J. M'Neil, Mr. Sharrah, Mr. Wilkinson, Mr. Spencer, Mr. C. Gerring, Mr. J. S. Harvey, Mr. Hustwick, Dr. Crace-Calvert, Mr. A. P. Baker, Mr. E. Fisher, Mr. F. J. Barrett, Mr. P. Sparrow, Mr. Lenton, "Oxygen."

PLEASANT BOTANICAL REMINISCENCES.

BY A. F. HASELDEN, F.L.S.

Papers setting forth the many advantages to be derived from the study of botany are not uncommon, but memory does not serve in reminding me of any written for this Journal upon the *enjoyment* obtained during the progress of botanical study, excepting two most excellent and notable, which formed the principal part, or, it might be said, the whole of Professor Bentley's opening addresses at the meetings of the Conference, of which he was President in the years 1866-7, *vide* PHARMACEUTICAL JOURNAL, Second Series, Vol. VIII. p. 108, and Vol. IX. p. 153. Should the lines which follow lead or induce any to turn back and read those addresses, the writer will have accomplished something. Not taking into account the satisfaction of well-regulated minds from the acquirement of knowledge generally, the study of botany offers gratifications beyond the gain of information, great as that is. The good botanical student will not be content with books, he will work in the school-room of Nature. The first gain will be that of becoming a lover of order, no small pleasure in itself. Without order and method in the progress, a great success must not be expected; persevering regularity in the work must be engendered; it is not a study at the outset, to be taken up now and then, or put aside for months; and it should be accepted in truthfulness and simple-mindedness; in every onward step there will be pleasure, never-ending sources of occupation; and what life, *devoid of occupation, is truly happy?* Mark the beauty of shape, the loveliness of colour, the almost boundless variety of flowers, grasses, ferns, mosses, algæ and fungi, from the very commencement, when learning that the cell is the foundation of vegetable structure; that the simplest plants are composed of individual cells; that those a little higher in the scale are made up of aggregations of cells; and from the formation of cells studying on until the majestic forest oak and beautiful palms are reached, there will be found a constant source of recreation. Think of the variety of forms of roots and underground stems; the differently-shaped leaves, their position on the stem and their office; the stems, the kinds of inflorescence and fruits; the internal and external structure, and the means of propagation. Putting aside generalities, let me draw upon the imagination, and picture the student, the real earnest student, rising in summer an hour or two sooner than the other inmates of the house; suppose him in the country or country town, the fresh morning air wafting gently through the open casement, now see him emerge with botanical case strapped across the back or fastened to the side, a stout stick, with well-curved handle, to help in stretching over a roadside ditch, or in hooking some flowers out of ordinary reach, a strong clasp-knife or small trowel in pocket to assist in digging round the roots, so as to enable him to secure the whole plant if possible,—the true botanist in some cases wants the roots, as well as leaves and flowers. Behold the glow of health upon his cheek as he returns for the morning meal. Unlike the sportsman who shoots the feathered race, or the angler coquetting with the finny tribe, the botanist is sure of sport; even when he does not obtain that which he is particularly seeking, he is certain to find some material for future examination and study. Though the honeysuckle, traveller's-joy or the dog-rose do not welcome him on the hedge, he may find, upon the turfy bank and roadside the slender harebell, yarrow, ragwort and toadflax; and in the meadows and cornfields, the gaudy poppy, the dandelion, daisy and buttercup; if when alone the enjoyment is good, how much more so when kindred spirits work the morning through! and when the noonday heat overtakes them near some village-green, when rest seems almost necessary, they wander on until they reach—

> "The hawthorn bush and seat beneath the shade
> For talking age and whispering lovers made."

Then sitting down upon the welcome bench, each from his box brings forth his stock of flowers, etc., and interchange is made of those which some have and some have not; then, one more experienced than the rest explains as well as he can the prominent points of difference between the specimens, enlarges upon the useful properties of one, and the dangerous peculiarities of another; how they may be best pressed and dried, fixed on sheets of paper, and arranged for the formation of an herbarium. And now wending the way towards home, if in early autumn time they pluck the bittersweet with berries bright and red from the hedge, or perchance the deadly nightshade with black and alluring but dangerous berries. Thus far some of the enjoyment of collecting at different times and seasons; then comes the satisfaction of sorting, arranging and determining the names and orders of some about which there was a doubt; also the innate feeling that the little stock of botanical knowledge is not all by the book. For those more advanced there remains the pleasure to be derived from the more recent discoveries and the communication of information often carried on by friendly correspondents. If an excuse may here be offered for those who do not take kindly to botany, it may be said that from the first this disadvantage has been attached to it, or the study of it, that it was considered as a part of medicine, and so whilst it was originally studied more as the means of discovering the qualities of herbs, etc., in their remedial capacity, the knowledge of them as plants or parts of the vegetable kingdom was not so much a matter of study or recreation, as a search after new remedies. I feel pretty sure that many a student has thrown up botany in disgust when left to himself, from the fact that at every step in the commencement of book teaching he feels as if he were learning the meanings of a long vocabulary of words derived from Greek and Latin roots; and it is rarely that this feeling is overcome, unless the student enjoy the advantages obtained from working under the direction of a professor or in a class with others. Having had the benefit of this, he knows how to work when left to himself. The enthusiastic botanist, like the painter, the musician, the linguist, or the author, is born a botanist; but a strong love of the science may be acquired, and a good acquaintance obtained, when its enjoyable part is better known and appreciated. In order to enjoy botany, it is not absolutely necessary that systems, orders, classes and alliances should at once be attacked. Being reminded that agreeable remembrances of botany should form the subject of this communication, I may sum up: there is, in the first place, the pleasure of acquired knowledge; secondly, that derived from the way in which it is acquired; thirdly, and not the least, the enjoyable association of kindred spirits; lastly, the healthy nature of it. I have purposely avoided the beaten track of mercantile gain and professional advantages, because I feel that there is in the pleasure to be derived more than sufficient to induce a love for the study of botany. I never pass down a country lane without finding amongst the wayside flowers food for enjoyment and contemplation.

Once more let me commend to all students the perusal of Professor Bentley's two addresses mentioned at the commencement of this communication, written with the view of encouraging the young, and reminding them that botany is not really the dry subject it has been too frequently designated, or at any rate that it has attached to it pleasant memories and associations.

A CHAPTER IN MICROSCOPY.

BY HENRY POCKLINGTON.

(*Concluded from page 442.*)

Optical Errors.—Errors of interpretation frequently arise out of certain well-known optical phenomena, and are less easily guarded against, because less expected. "Seeing is believing," says the old saw; but in optics seeing must very frequently be, *not* believing. One of these phenomena we have already glanced at in the case of the oil, air and water globules. A very similar case is that of the lacunæ in bone, so long mistaken for opaque radiating solids. Not unlike also are the cases of the concavity of the blood-corpuscle, the so-called tubular structure of the human hair, and the so-called hexagonal areolation of the valves of certain *Pleurosigmæ*. One rule may serve as guide here. Carefully alter the focus in the way we have just described. If the portion of the structure under view appear brightest when the distance between the objective and itself is *greatest*, and darkest when that distance is least, it may, with tolerable safety, be concluded that it is a superficial elevation. The rule is, of course, modified if the particular portion of the structure possess a different refractive power from its surroundings; but making allowances for this (any variation in this respect may be detected by altering the direction of the illuminating pencil), the rule may be relied upon with safety. The student may practise upon the eyes of insects, provided they be carefully mounted. We would recommend him to secure a really good specimen of the eye of a beetle (one in our possession, mounted by Mr. J. F. Barnett, of Tottenham, is exquisitely done), human hair mounted dry and in balsam, and a slide of *Pleurosigma formosum*, and to carefully study these under all possible conditions as regards the direction of the illuminating pencil. But, after all, the most perplexing phenomena are those due to diffraction. Perhaps, without plunging into mathematics, we may, in a few words, explain the cause of these phenomena before we attempt to discover a safeguard from their misleading tendencies.

These phenomena appear to have been first noted a little more than two centuries since by Grimaldi, of Bologna, but it is only within modern times that they have been thoroughly investigated. They are due to the fact, that a ray of light is, under certain circumstances, inflexed in passing the margin of an object. The phenomena may be easily observed if a diverging pencil of light be permitted to enter a dark room through a narrow aperture, and a knife-edge be held in the path of the pencil just above its point of divergence. The shadow of the object will be split down the centre by a bright line bordered with fringes of colours in harmonic progression; or, a grating of fine wires may be arranged so that no light shall enter the eye but has passed through the grating, when exceedingly beautiful effects, dependent upon the size and arrangement of the wires, will be produced. The phenomena are thus explained:* if the diverging rays, which are inflexed on one side of the pins or wires, meet those which are inflexed on the opposite side in the same phase of undulation (on crest or in trough of wave at same time), they coincide and produce a line of white light; whilst rays, which differ in their path, encounter each other under different phases, and interfere, producing either darkness or a coloured fringe. (The student at the seaside, or near a lake or pond, may study these phenomena at his leisure in visible waves of water.) Very similar in character to diffraction interferences are those known as thin-plate interferences, and we may conveniently study them together.

In microscopy we meet with the one when we study fine striæ, as in diatoms, some of which give a lovely iridescent glow when viewed by an intense beam of white light; the others, in such structures as the ramenta of Ceterach and certain vegetable hairs. Both are met with in certain histological preparations, where fine fibres lie side by side, or are interlaced, or where two membranes are closely superimposed. Very commonly in the barred, or pitted, vessels of plants, it is exceedingly difficult to decide whether the apparent puncture is complete, or whether the primal cell wall is still present, but uncovered by the later deposit, as it is visible only as a narrow band of a faint reddish colour, with, perhaps, a dark band round the centre. In a slide of the vessels of *Tropæolum majus* (nasturtium), now before us, there is a splendid illustration of this class of phenomena; and it was not without long and careful study that the true character of the structure could be made out, We did it at last by the use of homogeneous light, which, being obviously incapable of interference, enabled us to see, by aid of careful focusing, that there was really no complete aperture in the *cell under observation*, but that the later deposits of sclerogen had left the primal cell wall uncovered in those particular portions. This is, of course, a very common structure, the less frequent being the perforate one. The use of monochromatic light, in all cases where there is the least reason to suspect interference phenomena, is strongly to be advised. Careful use of the polarizer without analyser, but with and without selenite, is also, in many cases, of great service. The student may familiarize himself with these phenomena, and the way of dealing with them, by the careful study with low powers in a strong light of such things as these,—gratings of fine wires, meshes of fine threads or wires, films of mica having their surfaces broken up by being bent to a right angle and then reflexed, and, lastly, of such fine powder as the sporidia of *Lycoperdon* (puff-ball), and of various species of *Ustilago*. He will, after a course of such study, be able almost intuitively to pronounce as to the true character of the

* Brookes, 'Natural Philosophy,' 6th edition.

structure producing the interference, and find these very phenomena a great help instead of a plague and a torment.

A class of phenomena accompanying the use of "oblique illumination" should be considered here, but we must confine ourselves to pointing out the form the errors generally assume. The phenomena are strictly analogous to the second images seen when the image of an object is viewed in a thick looking-glass, and were, of course, due to successive reflections from the different surfaces of the mirror and its metallic coating. When such objects as diatoms are viewed by very oblique light from the mirror, these secondary images are very numerous, arising from successive reflections from the surfaces of the thin cover, glass slide, the object itself, and the medium in which it is mounted. These successive reflections produce the appearance known as false striæ, and may be detected by slightly changing the angle of incidence of the illuminating pencil, or by rotating the object in a horizontal plane.

Molecular Movements.—We must notice these very briefly, as our space has nearly run out. These, called often after their discoverer, *Brownian movements*, are hardly to be distinguished from those more properly called vital by any other than an experienced microscopist. Indigo, carmine or gamboge rubbed up in water is admirably adapted to show the movements, and a careful study of them will be the surest means of enabling the student to recognize them. Their want of power of choice (*i. e.* their movements are purely mechanical) is, perhaps, their sole distinguishing feature. The differences between Brownian and vital movements in small particles are so slight, that it is doubtful whether they can be described, or that anything but experience will enable the student to distinguish between them.

Certain sources of error of interpretation arising out of the use of the micro-polariscope and microspectroscope, must be deferred, as must also the discussion of a few other points with reference to the use of the ordinary stand. Enough has, it is hoped, been said to be of use to the student in microscopy, who, like the author, in his younger days especially, is pretty often at his wits' ends.

COD-LIVER OIL, ITS MANUFACTURE AND COMMERCE.

BY P. L. SIMMONDS.

(*Concluded from page* 444.)

In the *Journal de Pharmacie* for March 1866, my brother-in-law, Dr. Soubeiran, gave a description, with illustrations, of the apparatus and processes of manufacturing the oil which he found in operation in Norway, during his visit to the Bergen Fishery Exhibition. These seem to be chiefly two, one employed in many small establishments in Nordland, by which steam is conveyed by pipes from a boiler into closed casks containing the livers. These casks have cocks placed at different heights to draw off the oil as dissolved; the oil first obtained is much lighter in colour than that which comes away at the close of the operation. By this process a milky and turbid oil is obtained, without any bad taste, but which is less esteemed than that procured by more improved processes, as it is less rich in iodine and bromine principles, which become dissolved in the water introduced into the middle of the livers. To obviate this defect, in the larger number of factories established in Norway the livers are heated in boilers with double bottoms, which receive the steam, and in which the filtration proceeds slowly under the influence of heat. When the livers yield no more light oil, they are removed to a caldron holding from three to four barrels, and heated by fire, when a darker oil is obtained of which the Norwegians make great use for lighting purposes. After this the heat is increased, and, by boiling for about ten hours, the brown oil is obtained which is used for various industrial purposes. The resinous-looking residue is sold at about 5*s.* the barrel for manure. Unless care is taken in the selection of the livers and the preparation of the oil, it will often have an unpleasant flavour. Thus the liver of the coal-fish (*Gadus carbonarius*) does not possess the pure flavour and peculiar properties of the true cod-liver oil, and the livers of some of the cod caught late in the season, which have fed on the capelin (*Mallotus grœnlandicus*), yield an oil far from agreeable, and of a totally different flavour.

On the coast of North America many cod are caught with diseased livers, that evidence of a disordered or weak stomach. The sick fish are called "logies," from the heavy, lifeless feel of them on the line as they are drawn up from the bottom. The livers of logy cod are always more or less diseased. They are destitute of oil and of a dark colour, and not unfrequently contain abscesses filled with pus. Young fish are very rarely found to be inwardly diseased, so that, perhaps, after all the logies are aged individuals, whose vital organs are impaired by the gradual decay of nature.

Attention has been drawn from time to time to other fish-oils which might be used medicinally, but looking at the abundance of cod-liver oil in the two great seats of production, there seems little necessity for resorting to these, unless, perhaps, in India and Australia, where a native product might be more easily and cheaply obtained. The oil obtained from a small fish called the oolachan, abundant about Vancouver's Island, and the oil obtained from the *Halicore Dugong* have been recommended as substitutes for cod-liver oil.

Several years ago Mr. Gobley, of the School of Pharmacy, was engaged at Paris in preparing a medicinal oil from the liver of the ray, which was said to be much less disagreeable in flavour and odour than cod-liver oil. About the same time Professor Owen drew attention, in his course of lectures, to the services that might be rendered to medicine by the livers of the numerous sharks and dog-fish which are met with on our coasts, and especially in the equatorial seas, and which are generally rejected by fishermen. The advice of Professor Owen seems to have been followed, for in many localities, as on the coast of Norway, Canada, Australia and the Indian seas, the shark fishery is carried on largely for the oil obtained. The shark fishery of Norway yields annually 5000 barrels of liver.

In India, shark oil from the liver is prepared in great quantity at the ports of Mangalore and Tillichery, and an extensive fishery is carried on at Bombay; twenty years ago as much as 700,000 gallons of this oil was shipped from the ports of the Madras Presidency. M. Collas, principal naval surgeon and chief of the health establishments in

French India, states* that he has found shark-liver oil equally efficacious with cod-liver oil, and, moreover, has noticed its great usefulness as a medicine in certain ulcers of the inferior members, very common in equatorial regions, and against which other medicines were usually found ineffective.

The abundance of sharks in all seas, and especially in those warm latitudes, and the facility of the fishery gives an interest to this subject in a commercial point of view.

The medicinal employment of shark-liver oil opens up, however, a scientific question of some importance. Sauvages, the celebrated professor of Montpellier, has recorded a case of poisoning produced by the liver of *Squalus canicula*. Do these venomous properties belong to certain species only, or are they merely developed in certain conditions? We know that but little care is employed in the East in cleansing the livers or obtaining the oil, and putrefaction soon ensues in tropical climates. We would especially direct the attention of persons occupied with chemical inquiries and natural history to the study of this question, which is one highly interesting in a zoological and sanitary point of view to the inhabitants of warm countries.

THE PHYSIOLOGICAL ACTION OF CHLORAL HYDRATE.

BY M. H. BYASSON.

In a note presented to the Académie des Sciences,† in anticipation of a more detailed memoir, the author gives some of the results of an investigation having reference specially to the physiological action of chloral hydrate. The conclusions, which differ from those of Dr. Oscar Liebreich, and have been founded upon the comparative action of chloroform, formate of soda, hydrate of chloral, trichloracetic acid and trichloracetate of soda upon frogs, rats and dogs,—and incidentally of hydrate of chloral upon men,—are formulated as follows:—

1. The action of hydrate of chloral upon similar organisms is different from that of chloroform.
2. The action is peculiar to that body, and may be considered as the result of two products into which it is decomposed, principally upon contact with the blood, viz. chloroform and formic acid.
3. Trichloracetic acid and trichloracetate of soda differ from hydrate of chloral in their action upon the animal organism, since they both break up into chloroform and acetic acid.

A part of the chloroform formed by the action of the alkaline carbonates of the blood upon the hydrate of chloral is eliminated by the lungs; and a part of the formic acid is found in the urine in the shape of formate of soda. As a practical result of the experiments, the author found that he could distinguish three degrees, produced gradually and successively by increasing doses, but varying in individuals.

(1.) A feebly soporific action and slight sedative effect upon the sensitive nervous system, which may be accompanied by intervals of a peculiar agitation, similar to that produced by some dreams.

(2.) An energetic and powerful soporific action, with diminution of sensibility. Then follows a period of calm slumber of variable duration, but without apparent disturbance to the principal functions of life. By means of successive doses administered when the effects of the previous ones have nearly disappeared, this slumber may be extended during a comparatively long time.

(3.) Anæsthetic action, with complete loss of sensibility and muscular power. Death has generally been found to follow when this stage has been reached, in consequence of the inability of the organism to sustain the increasing action of so large a quantity of the drug until its complete transformation and elimination.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Potassæ Bicarbonas, $KHCO_3$.—A pretty strong solution of carbonate of potassium is exposed to the action of carbonic acid gas, till, in consequence of the formation of the bicarbonate, and the inferior solubility of that salt, a crop of crystals has been deposited. This is one of those cases in which the manufacturer might have fairly been left to his own discretion as to the mode of operating, and the elaborate description of the apparatus to be employed omitted, with no disadvantage, from the Pharmacopœia.

The bicarbonate differs from the carbonate in being less soluble in water, in crystallizing in larger and more distinct crystals, in not being deliquescent, and in giving, with a cold solution of sulphate of magnesium, no precipitate.

Bicarbonate of potassium dissolves in about four times its weight of water.

Potassæ Bichromas.—Chromium is found chiefly in the form of 'chrome-iron-stone,' a compound having the formula $FeCr_2O_4$, or $FeO.Cr_2O_3$, and analogous to magnetic iron ore. This is pulverized and roasted with a mixture of carbonate of potassium and chalk, sometimes with the addition of a little nitrate of potassium, in a furnace through which a current of air passes. The ore is gradually disintegrated with formation of chromate of potassium and oxide of iron.

$$2\,[FeOCr_2O_3] + 4K_2CO_3 + 7O$$
$$= Fe_2O_3 + 4K_2CrO_4 + 4CO_2.$$

The chalk is added to keep the mixture in a porous state by diminishing its fusibility; a little chromate of calcium is thus frequently produced.

The solution obtained by treating the fused mass with water, and acidulating with sulphuric acid, yields red chromate of potassium. [§ In large red, transparent four-sided tables, anhydrous; fuses below redness; at a higher temperature is decomposed, yielding green oxide of chromium and yellow chromate of potash, which may be separated by dissolving the latter in water.

$$(2K_2Cr_2O_7 = 2K_2CrO_4 + 2CrO_3$$
$$= 2K_2CrO_4 + Cr_2O_3 + 3O.)$$

The bichromate dissolved in water gives a yellowish-white precipitate with chloride of barium ($BaCrO_4$), and a purplish-red precipitate with nitrate of silver (Ag_2CrO_4), and both these precipitates are soluble in diluted nitric acid. The solution also, when digested with sulphuric acid and rectified spirit, acquires an emerald green colour.] This last reaction results in the formation of the green sulphate of chromium, sulphate of potassium, and a mixture of aldehyde and acetic acid, as the results of the oxidation of the alcohol. It is quite parallel with that by which valerianic acid is obtained by the oxidizing action of the same mixture upon amylic alcohol. A mixture of potassic chromate with an acid is, indeed, employed very frequently as an agent by which the oxidation of organic as well as other substances is effected; for example, in the conversion of cinnamic acid into hydride of benzoyl (see B. P. Styrax Præp.), and in the volumetric process for the estimation of ferrous salts. Bichromate of potassium is one of a singular class of salts which contain the elements of the normal neutral salt and of the acid anhydride, *e. g.*:—

Bichromate of potassium . .	$\left\{\begin{array}{l} K_2Cr_2O_7, \text{ or} \\ K_2CrO_4 . CrO_3 \end{array}\right\}$
Nordhausen sulphuric acid .	$\left\{\begin{array}{l} H_2S_2O_7, \text{ or} \\ H_2SO_4 . SO_3 \end{array}\right\}$
Bisulphate of potassium . .	$\left\{\begin{array}{l} K_2S_2O_7, \text{ or} \\ K_2SO_4 . SO_3 \end{array}\right\}$
Pyrophosphoric acid . . .	$\left\{\begin{array}{l} H_4P_2O_7, \text{ or} \\ H_3PO_4 . HPO_3 \end{array}\right\}$

CONTRIBUTIONS TO THE HISTORY OF THE OPIUM ALKALOIDS.*

BY C. R. A. WRIGHT, D.SC.

Lecturer on Chemistry in St. Mary's Hospital Medical School.

Part III.

1. *Action of Hydriodic Acid on Codeia in Presence of Phosphorus.*

In Parts I. and II. of these researches the action of hydrobromic acid on codeia and its derivatives has been partially investigated; and as the action of this acid seems to be in some respects similar to, but in others different from that of hydrochloric acid, it appeared to be of interest to examine the action of hydriodic acid also.

Some preliminary experiments on this subject, made two or three years ago in conjunction with the late Dr. A. Matthiessen, showed that when codeia is boiled with a large excess of strong hydriodic acid, no appreciable quantity of methyl iodide is evolved even after some hours' treatment; a brown tarry mass containing much free iodine was produced, but at the time nothing fit for analysis was obtained from this; since then, Dr. Matthiessen and Mr. Burnside† have corroborated the non-formation of methyl iodide under these circumstances.

If, however, phosphorus be added simultaneously with the hydriodic acid, so as to prevent the accumulation of free iodine, methyl iodide is evolved at 100° and upwards in quantity close upon that required for the equation—

$$\underbrace{C_{18}H_{21}NO_3}_{\text{Codeia.}} + HI = CH_3I + \underbrace{C_{17}H_{19}NO_3}_{\text{Morphia.}}:$$

hitherto, however, no body of this latter formula has been isolated from the products of the reaction, the substances ultimately formed being derived from a base containing H_2 more than morphia.

The hydriodic acid was obtained, in the first instance, by the action of hydric sulphide on iodide and water; in the dilute acid thus got iodine was dissolved, and the whole digested at a very gentle heat with phosphorus, more iodine solution being added from time to time; finally, the whole was distilled several times from potassium iodide. A colourless acid of sp. gr. 1·7 to 1·75, and containing 50 to 55 per cent. of HI, was thus obtained, and preserved colourless by keeping a stick of phosphorus in the bottle. The codeia used in these experiments was part of a further supply most liberally presented by Messrs. Macfarlan, of Edinburgh.

On heating on the water-bath a mixture of 10 parts codeia, 30 to 50 of this acid, and 1 of phosphorus, the evolution of methyl iodide is noticed in a few minutes; simultaneously the liquid becomes brown, indicating the separation of free iodine; after two or three hours the brown colour disappears, and the evolution of methyl iodide ceases. If the liquid be heated to gentle ebullition, at first the same effects ensue, but more quickly; the resulting product, however, varies in composition, according to the temperature at which the reaction was effected.

In one experiment 55 grms. of codeia yielded by condensation 22·5 grms. of methyl iodide, the theoretical yield being 24·6 from crystallized codeia, $C_{18}H_{21}NO_3H_2O$; hence upwards of 90 per cent. of the theoretical yield was obtained. In order to prove the elimination of 1-18th part of the carbon in the form of methyl iodide, 4·3045 grms. of codeia, dried at 140° to 150° C., was heated to gentle ebullition with 30 grms. of 55 per cent. of hydriodic acid and about 2 of phosphorus; the vapours evolved were passed through a flask to condense aqueous vapour, and then through a combustion-tube filled with red-hot lead chromate, the CO_2 produced being absorbed in the usual way,—an aspirator being attached at the far end so as to create a diminished pressure throughout the apparatus, and thus guard against loss of methyl iodide vapour by leakage at any of the numerous corks and joints.* After three hours a current of pure oxygen was let through the apparatus to sweep out the last traces of methyl iodide vapour from the flasks, and ensure the perfect combustion of deposited carbonaceous particles.

4·3045 grms. codeia thus gave 0·617 grm. CO_2.

0·3720 grm. codeia, burnt in the usual way, gave 0·9830 CO_2.

	Found.	Calculated.
(A) Percentage of carbon evolved as CH_3I . .	3·91	4·013
(B) Percentage of carbon in codeia used . .	72·07	72·241
Ratio of A to B	$\frac{3·91}{72·07} = \frac{1}{18·4}$	$\frac{4·013}{72·241} = \frac{1}{18}$

In another experiment not carried to a complete conclusion, the CO_2 collected represented 3·7 per cent. of the codeia used.

The methyl iodide produced was found, after washing with water, drying over $CaCl_2$, and distillation, to be free from traces of dissolved phosphorus, to boil at 42° to 45° C., and to correspond in every respect with the ordinary methyl iodide.

If the reaction with hydriodic acid takes place on the water-bath, the resulting product appears to have the composition $C_{68}H_{86}I_2N_4O_{12}, 4HI$; but if the mixture be heated to gentle ebullition throughout, the temperature not being allowed to exceed 110° to 115° from loss of aqueous fluid by evaporation, the substance obtained contains the elements of two molecules of water less, $= C_{68}H_{82}I_2N_4O_{10}, 4HI$; whilst if the mixture be rapidly

* Read before the Royal Society, November 16, 1871.

† Proceedings of the Royal Society, vol. xix. p. 71.

* This device may be applied with advantage to the ordinary processes for combustion, blowing out of the tube as well as loss by traces of leakage being thus avoided.

boiled, so that by evaporation the boiling-point rises to 130° and upwards, the ultimate product contains less oxygen than this last body, being $C_{68}H_{82}I_2N_4O_6, 4HI$. These three formulæ might each be halved; but inasmuch as compounds containing not less than C_{68} have been got from these products by simple treatments, the higher formulæ are more probable.

All three substances are, while moist, colourless tars, drying at 100° to brittle waxy-looking masses, not fusing at 100° when perfectly dry; they are soluble in hot water, a decomposition being thereby produced; while moist they appear to absorb oxygen with avidity, rapidly becoming yellow or orange. They are also extremely hygroscopic, and from the high percentage of iodine contained, the ease with which they decompose on heating, and the difficulty combustible carbon left, their analysis is a matter of some considerable difficulty. From all these circumstances combined, the numbers obtained do not always accord quite as closely as might be expected in the case of crystalline and easily purified substances.

To obtain the compound $C_{68}H_{86}I_2N_4O_{12}, 4HI$, 10 parts of codeia, 30 of 55 per cent. hydriodic acid, and 1 of phosphorus may be heated on the water-bath for three to four hours, at the end of which time the evolution of methyl iodide has entirely ceased: by filtering the syrupy hot liquid through asbestos to separate particles of amorphous phosphorus and addition of a little water when cold, a colourless tar is precipitated, which soon sets to a hard brittle mass: this is broken up and thoroughly washed with water to separate the phosphorus acids produced simultaneously, and finally freed from moisture as far as possible by pressure between filter paper, and dried at 100°.

The same body may also be obtained by dissolving the original substance in slightly warm water, precipitating with sodium carbonate, and extraction of the mass thus thrown down with ether, and agitation of the first portions of the ether extract with hydriodic acid: the tar thus got is identical in all respects with the original substance. After drying at 100° the following numbers were obtained:—

(A) Prepared by the first method:—
0·3785 grm. gave 0·588 CO_2 and 0·173 H_2O.
0·359 grm. 0·2535 AgI.

(B) Prepared by ether process:—
0·357 grm. gave 0·5655 CO_2 and 0·165 H_2O.
0·2635 grm. gave 0·1895 AgI.

(C) Another specimen prepared by ether process:—
0·316 grm. gave 0·493 CO_2 and 0·135 H_2O.
0·2865 grm. gave 0·2025 AgI.

	Calculated.		Found. A.	B.	C.	Mean.
C_{68}	816	42·59	42·36	43·20	42·54	42·70
H_{90}	90	4·70	5·08	5·14	4·75	4·99
I_6	762	39·77	38·16	38·87	38·19	38·41

O_{12}	192	10·02				
	1916	100·00				

$C_{68}H_{86}I_2N_4O_{12}, 4HI$.

The falling short in the percentage of iodine found in these specimens is readily accounted for by the action of the water which necessarily adheres to the tarry product got by either of the above processes; it will be subsequently shown that by the action of water on this body the elements of HI are removed from it.

This compound is apparently formed by the reaction—

$$\underbrace{4(C_{18}H_{21}NO_3, HI)}_{\text{Codeia hydriodate.}} + 14HI =$$
$$= 4CH_3I + I_8 + \underbrace{C_{68}H_{86}I_2N_4O_{12}, 4HI.}_{\text{New body.}}$$

* All combustions given in this paper were made with lead chromate and oxygen; and the iodine determinations by boiling with nitric acid and silver nitrate.

The iodine thus set free is, of course, reconverted into HI by the action of the phosphorus, a mixture of phosphorous and phosphoric acids being thereby produced. The reaction,

$$3I_2 + P_2 + 6H_2O = 2H_3PO_3 + 6HI,$$

requires for 50 grms. of codeia 3·45 grms. of phosphorus to be converted into phosphorous acid; whilst the equation $5I_2 + P_2 + 8H_2O = 2H_3PO_4 + 8HI$ requires 2·07 grms. to be converted into phosphoric acid. In one experiment 2·8 grms. of phosphorus, as nearly as could be estimated, were found to have become converted into the mixture of the two acids, 50 grms. of codeia having been employed.

On attempting to procure the free base $C_{68}H_{86}I_2N_4O_{12}$ from the hydriodate got as above, by precipitation with sodium carbonate, a snow-white mass was obtained containing, besides a small quantity of the desired base (soluble in ether), a large quantity of two other bases derived from this one (but sparingly soluble in ether). The description of the products thus got will be given in a subsequent section.

By treating codeia with hydriodic acid and phosphorus as above described, but at a temperature of gentle ebullition, not rising above 115°, a product is got on filtration through asbestos and precipitation by water containing apparently $2H_2O$ less than the preceding compound. Dried at 100°.

0·302 grm. gave 0·475 CO_2 and 0·135 H_2O.
0·248 grms. gave 0·1845 AgI.

	Calculated.		Found.
C_{68}	816	43·40	42·89
H_{86}	86	4·58	4·97
I_6	762	40·53	40·20
N_4	56	2·98	
O_{10}	160	8·51	
$C_{68}H_{82}I_2N_4O_{10}, 4HI$	1880	100·00	

Hence this substance is formed from the preceding one by the reaction—

$$C_{68}H_{86}I_2N_4O_{12}, 4HI = 2H_2O + C_{68}H_{82}I_2N_4O_{10}, 4HI.$$

If codeia, hydriodic acid (3 to 5 parts), and phosphorus be heated to rapid ebullition, so that most of the aqueous portion distils off along with the CH_3I formed, the boiling-point gradually rises to 130° or a little above, at which temperature the colourless liquid begins again to become slightly brown; on precipitation of the filtered product with water, etc., as before, the following numbers were obtained after drying at 100°:—

Specimen A. 0·3575 grm. gave 0·589 CO_2 and 0·168 H_2O.
0·402 „ 0·307 AgI.
Specimen B. 0·358 „ 0·583 CO_2 and 0·164 H_2O.
0·369 „ 0·2815 AgI.
Specimen C. 0·3855 „ 6·635 CO_2 and 0·178 H_2O.
3·363 „ 0·276 AgI.

	Calculated.		Found. A.	B.	C.	Mean.
C_{68}	816	44·93	44·92	44·41	44·91	44·75

$C_{68}H_{82}I_2N_4O_6, 4HI$

Hence this substance is formed from the preceding one by the reaction—

$$C_{68}H_{82}I_2N_4O_{10}, 4HI + 8HI =$$
$$= I_8 + 4H_2O + C_{68}H_{82}I_2N_4O_6, 4HI.$$

(*To be continued.*)

NOTES ON CARBOLIC ACID.

BY WILLIAM C. BAKES.

Few substances have acquired greater popularity, and given such general satisfaction as carbolic acid. For a long time it was exclusively used by the medical profession, but the public having heard of its antiseptic and disinfectant properties have adopted it in various forms as one of their household requisites.

Its use as a remedial agent dates from 1859, when M. Le Beuf, of Bayonne, France, employed the then crude carbolic acid in the form of a saponaceous emulsion. He assisted in the work of M. Lemaire, of Paris, who has made it the foundation of a laborious research. The two investigators sent to the Academy of Medicine a paper on the value of the emulsion as an application to gangrenous ulcers. M. Lemaire continued his investigation, and published an elaborate treatise in 1863, in which he narrated a series of experiments in which carbolic acid was employed as a means for the destruction of low forms of animal and vegetable life, as a preventive of fermentation and putrefaction, as an external application in cases of ulcerating and suppurating surfaces, as well as an internal remedy in zymotic and other diseases. While carbolic acid was attracting attention as a disinfecting agent, experiments were being made as to its use in the arts. Laurent, in 1841, after a series of investigations, produced picric acid by the action of nitric acid upon carbolic acid. Picric acid is used as a yellow dye, and from it are derived picramic acid and isopurpurate of ammonium, yielding rich brown and garnet hues.

In 1865 Professor Lister began the use of carbolic acid in surgical cases attended with suppuration, and gave the result of his investigations in several communications to the *Lancet*, in the March and July numbers of 1867.

To the pharmaceutist the preparations of carbolic acid are of some interest, and demands are often made for the various combinations without any definite formula.

A valuable work of 356 pages has recently been published, entitled 'The Antiseptic System: a Treatise on Carbolic Acid and its Compounds,' etc., by A. E. Sansom, M.D., of London, which contains much useful information, relating not only to the chemistry of carbolic acid, but to its general employment in medicine. In the appendix a series of formulæ are given as follows:—

1. *Liquefied Carbolic Acid.—A.* Calvert's purest (No. 1) acid, liquefied by placing the bottle containing it in hot water, 9 parts; water, 1 part. Mix well.—*Calvert.*

B. Pure carbolic acid, 15 parts; alcohol, 1 part. Mix well. This keeps fluid at all ordinary temperatures.—*Sansom.*

For many purposes, especially for dispensing, it is convenient to keep the acid in a liquid form, otherwise the crystals must be melted by heat each time that the acid is employed.

2. *Solution of Carbolic Acid in Water.*—To obtain uniform solution, it is better to slake the carbolic acid with four times its bulk of hot water, and then to add a sufficiency of cold water; or the carbolic acid may be first mingled with alcohol, which causes more ready solubility, before the addition of cold water. Water will not dissolve more than one-twentieth of its bulk of carbolic acid.

3. *Alcoholized Carbolic Acid* (Acide Phénique Alcoolisé)—Alcohol (90°), crystallized carbolic acid, equal parts. Mix, and keep in a well-stoppered bottle. Used for making carbolized solutions, etc. Being more fluid than carbolic acid, it more readily penetrates the tissues. Useful in poisoned wounds, for application to smallpox pustules, etc.—*Lemaire.*

4. *Etherized Carbolic Acid* (Ether Phéniqué).—Sulphuric ether, 100 parts; carbolic acid, 1 part. Used for insufflation in catarrh of Eustachian tube.—*Lemaire.*

5. *Carbolized Vinegar* (Vinaigre Phéniqué).—Ordinary vinegar, 4 parts; carbolic acid, 1 part. Mix. For use, instead of aromatic vinegar, as a disinfectant, etc.—*Quesneville.*

6. *Glycerinum Acidi Carbolici.*—Carbolic acid, 1 ounce; glycerine, 4 fluid ounces. Rub them together in a mortar until the acid is dissolved.—*British Pharmacopœia.*

7. *Carbolized Glycerine* (Glycerine Phéniquée).—Pure glycerine, 100 parts; carbolic acid, 1 part. Mix. For impetigo, chronic eczema, lichen, prurigo and pemphigus.—*Lemaire.*

8. *Syrup of Carbolic Acid* (Sirop d'Acide Phénique).—Simple syrup, 100 parts; carbolic acid, crystallized, 1 part. Mix.—*Chaumelle.*

9. *Carbolic Acid Liniment.*—For counter-irritation.

A. Alcohol, 50 parts; carbolic acid, 1 part. Mix.—*Lemaire.*

B. Olive oil, 7 parts; carbolic acid, 1 part. Mix.—*Sansom.*

10. *Compound Disinfectant Solution.*—Water, 1000 parts; carbolic acid, 10 parts; sulphate of zinc or sulphate of iron, 3 parts. Mix. Carbolic acid has no chemical action on sulphuretted hydrogen or carbonate of ammonium. When it is employed alone as a disinfectant, deodorization does not take place until the gases have disappeared by diffusion. The sulphates change the sulphuretted hydrogen into sulphides, and the carbonate of ammonium into metallic carbonate and ammonium sulphate,—all inodorous compounds.—*Lemaire.*

11. *The Süvern Deodorant.*—Good quicklime, $1\frac{1}{2}$ bushels, put in a cask, slaked, and well stirred; coal tar, 10 lb. Mix thoroughly, then add magnesium chloride, 15 lb., dissolved in hot water. Mix again, and add hot water until the mass is liquid enough to drop slowly from a stick plunged into it, and then withdrawn. The magnesium chloride forms deliquescent calcium chloride. Magnesia being liberated, this prevents caking and adherence to pipes, which is a defect when lime alone is used.—*Parkes.*

12. *Carbolized Earth* (Terre Coaltarée).—Common loam, passed through a sieve, 100 parts; coal tar, 2 parts. Mix intimately. Disinfectant for crops and for destruction of noxious insects.—*Lemaire.*

13. *Solution of Carbolic Acid for the Toilette.*—Crystallized carbolic acid, 10 parts; essence of millefleur, 1 part; tincture of *Quillaya saponaria*, 50 parts; water, 1000 parts. Mix. The saponin replaces soap with advantage. The above should be employed, diluted with ten times its bulk of water, for disinfecting the skin, for washing the hands after any risk of contagion or inoculation, etc.—*Lemaire.*

14. *Tincture of Saponin*, as used in the foregoing preparation, is thus made: Bark of *Quillaya saponaria*, 1 part; alcohol (90°), 4 parts. Heat to ebullition, and filter.—*Le Beuf.*

15. *Carbolized Water for the Teeth.*—Water, 1000 parts; essence of meat, 2 parts; tincture of saponin, 50 parts; pure carbolic acid, 10 parts. Mix. A dessertspoonful in a quarter of a tumblerful of water, serves as an excellent preparation for cleansing and preserving the teeth.

16. *Carbolized Ointment.*—Purified lard, 100 parts; carbolic acid, 1 part. Mix. Considered of some service in skin affections; but, modified as it is by the fat, it cannot replace the aqueous solution of carbolic acid.—*Lemaire.*

17. *Carbolized Amylaceous Ointment.*—Pure starch, 3 parts; hot water, 20 parts. Mix, in the ordinary way (the starch being made first into a paste with cold water, and then hot water added), to a stiff consistence; then add olive oil 1 part, glycerine 3 parts, carbolic acid 1 part, and thoroughly mix in a mortar. When cool this is a soft jelly, which can easily be applied as ordinary ointment. It is much more efficacious than one the basis of which is entirely fat, and it is an agreeably cool application.—*Sansom.*

18. *Carbolized Oil.—A.* Crystallized carbolic acid, 1 part; boiled linseed oil, 4 parts. Dissolve.—*Lister.*

B. Pure carbolic acid, 1 part; olive oil, 6 parts. Olive oil is better than linseed oil as a vehicle, as the latter is more prone to oxidation.—*Calvert.*

19. *Carbolized Putty.*—Carbolized oil, about 6 tablespoonfuls; common whiting (chalk), sufficient to make a firm paste.—*Lister.*

20. *Antiseptic Lead Plaster.*—Olive oil, 12 parts (by measure); litharge (finely ground), 12 parts (by weight); beeswax, 3 parts (by weight); crystallized carbolic acid, 2½ parts (by weight). Heat half the olive oil over a slow fire; then add the litharge gradually, stirring continually until the mass becomes thick or a little stiff; then add the other half of the oil, stirring, as before, until it becomes thick again. Then add the wax gradually till the liquid again thickens. Remove from the fire and add the acid, stirring briskly till thoroughly mixed. Cover up close, and set aside to allow all the residual litharge to settle; then pour off the fluid, and spread upon calico to the proper thickness. The plaster made in this way can be spread by machine and kept rolled in stock, and if in a well-fitting tin canister will retain its virtues for any length of time.—*Lister.*

21. *Antiseptic Lac Plaster.*—Shellac, 3 parts; crystallized carbolic acid, 1 part. Heat the lac with about one-third of the carbolic acid over a slow fire till the lac is completely melted; then remove from the fire and add the remainder of the acid, and stir briskly till the ingredients are thoroughly mixed. Strain through muslin, and pour into the machine for spreading plaster, and when the liquid has thickened by cooling to a degree ascertained by experience, spread to the thickness of about one-fiftieth of an inch.

Afterwards, brush over the surface of the plaster lightly with a solution of gutta percha in about 30 parts of bisulphide of carbon. When the sulphide has all evaporated, the plaster may be piled in suitable lengths in a tin box without adhering, or rolled up and kept in a canister.—*Lister.*

22. *Antiseptic Cere-cloth.*—Cloth or thin calico is saturated with cerate (made after the following formula), by simply drawing a portion through it while in a fluid state, or in pieces of any length and width, by rolling, by means of a machine, the calico over cylinders containing cold water, as fast as it has taken up the cerate.

A. Strongest Cerate.—Calvert's pure carbolic acid, liquefied, 3 fluid ounces; olive oil (coloured red with alkanet root to distinguish the cerate), 1½ fluid ounces; yellow wax, liquefied, 1½ fluid ounces; paraffin, liquefied, 6 fluid ounces. Mix.

B. Medium Strength.—Pure carbolic acid, 2 fluid ounces; olive oil, 2½ fluid ounces; yellow wax, 2½ fluid ounces; paraffin, 5 fluid ounces. Mix.

C. Weakest.—Pure carbolic acid, 1½ fluid ounce; olive oil, 1 fluid ounce and 6 drachms; white wax, 1 fluid ounce and 6 drachms; paraffin, 7 fluid ounces. Mix.

23. *Antiseptic Muslin Gauze.*—Paraffin, 16 parts; resin, 4 parts; crystallized carbolic acid, 1 part. Melt together. Cheap muslin gauze is dipped in the melted mass and well wrung or pressed while hot. A good substitute for oakum as an antiseptic covering for wounds, unirritating to the most sensitive skin, highly retentive of the acid, and almost destitute of odour. It should, when used, be folded in about eight layers. It loses the paraffin and resin when washed in boiling-water, so the same gauze may be used repeatedly.—*Lister.*

24. *Protective against Local Irritating Effects of Carbolic Acid in Antiseptic Dressings.*—Varnish oiled silk on both surfaces with copal varnish. When dry, brush over with a mixture of starch and dextrin, to give it a film of material soluble in water, so that it becomes uniformly moistened when dipped into antiseptic lotion. When not at hand, common oiled silk may be used as a substitute for it, if smeared with an oily solution of carbolic acid, and used in two layers, to make up for its inferior inefficiency.—*Lister.*

25. *Antiseptic Adhesive Plaster.*—Dip ordinary strapping in hot solution of carbolic acid, made by mixing 1 part of 1 to 20 lotion with 2 parts of boiling water. Will adhere to a moist skin, so that it may be employed under spray when advisable.—*Lister.*

26. *Carbolized Powders.*—Pure liquefied carbolic acid, 5 parts; alcohol, 5 parts. Mix. Add by degrees 100 parts of one of the following powders: Lycopodium, starch, charcoal, plaster of Paris. The proportions of carbolic acid can be increased or decreased as desired.—*Sansom.*

27. *Antiseptic Catgut Ligature.*—Catgut of the thickness required is to be kept steeped in carbolized olive oil (1 pint in 5), with a very small quantity of water diffused throughout it.—*Lister.*

28. *Aceto-Carbolic Solution for Tinea and Scabies.*—Acetic acid (pyroligneous), 8°, 20 parts; pure carbolic acid, 5 parts; water, 75 parts. Mix the two acids and add the water. The acetic acid favours penetration through the epidermis. For tinea, apply the liquid once a day over the diseased parts by means of a brush. For scabies, sponge all the parts. The clothes, etc., of the affected individual should also be treated with the liquid.—*Lemaire.*

29. *Carbolized Gargle for Diphtheria, Tonsillitis, etc.*—Carbolic acid, 20 minims; acetic acid, ½ drachm; honey, 2 fluid ounces; tincture of myrrh, 2 fluid drachms; water, 6 fluid ounces. The carbolic and acetic acids to be well shaken together before the other ingredients are added.—*Charles Sedgwick, jun.*

30. *Carbolized Mixture for Zymotic Diseases.*—Carbolic acid, acetic acid, of each 1 drachm to 1½ fluid drachm; tincture of opium, 1 fluid drachm; chloric ether, 1 fluid drachm; water, 8 fluid ounces. A tablespoonful every four hours until the fever has subsided.—*Dr. Alex. Keith.*

31. *Mixture of Quinine and Sulpho-Carbolate of Sodium.* Quinine sulphate, 1 grain; sulphuric acid, 5 minims. Dissolve, and add to the solution of sodium, sulphocarbolate, 20 grains; in water, 1 fluid ounce.—*Author.*
—*American Journal of Pharmacy.*

THE POLLUTION OF RIVERS.

(*Concluded from page* 428.)

The Commissioners have not rested content with publishing an account of the evil; they have also endeavoured to point out how it might be remedied, and that inexpensively, and sometimes with actual profit. The utilization of the waste liquors of manufacturers appears to admit, in some cases, of being practically carried out. This will be best shown by giving some particulars as to their composition.

Thus, a sample of the waste water from one of the vats in Messrs. Bright and Co.'s carpet factory at Rochdale, contained a large proportion of nitrogenous organic matter and ammonia, sufficient to render it valuable for irrigation, as seen from the following analysis:—

100,000 parts contained:—

Total solid matters in solution	103·10
Organic carbon	14·924
Organic nitrogen	·925
Ammonia	1·144
Total combined nitrogen	1·867
Arsenic	·012

The following is an estimate of waste stuff from the weekly manufacture of rather more than 500 pieces of broad cloth in the Stroud district:—Grease and dirt (removed from raw wool), 12 tons; urine, 14 tons; oil in carding, 2 tons; glue, 10 cwt.; pig's dung, 2½ tons; pig's blood, 2¼ tons; urine (collected from house to house), 25 tons; soda, 1 ton; soap, 2½ tons; Fuller's earth, 2½ tons; dye stuffs, 20 tons; alum, 2 tons.

The composition of the waste liquor from flannel washing proves to be, in the case examined, a most valuable manure, one hundredweight of it being worth, for this purpose, more than one ton of London sewage. The discharge of such liquors into rivers is a reckless waste. The following analysis of a sample of wool-suds (the liquid in which raw wool has been scoured) is an illustration of both the very noxious character of this liquid, and the great value which it possesses for agricultural purposes, as evidenced by the very high proportion of total combined nitrogen which it contains:—

100,000 parts of this liquid gave:—

Total solid matters in solution	1099·4
Organic carbon	132·48
Organic nitrogen	9·88
Ammonia	54·61
Total combined nitrogen	54·85
Mineral suspended matters	870·95
Organic suspended matters	2611·65
Arsenic	Traces.

In dealing with the subject of the remedies to be applied, the Commissioners call attention to the importance of keeping the very foul portion of the waste liquids separate from those of comparatively larger volume, but possessing so slight a polluting character as to render them admissible into watercourses without injury.

Such a separation of polluting from comparatively innocuous liquids would present no formidable difficulties to the manufacturer, whilst it would greatly facilitate the purification of the really noxious portion of the discharges, inasmuch as the volume of polluting water requiring remedial treatment would be immensely reduced. Moreover these liquids, both on account of their greater concentration and by reason of their containing a larger proportion of combined nitrogen, have a considerable manure value, while the extraction of highly polluting matter, as for instance the oil from the soapsuds obtained in the washing both of the raw and manufactured material, yields, in some cases, a handsome profit. Partly on this account, and partly because of proceedings in equity or of actions at law, instances are not wanting of more or less successful attempts at the purification of these refuse liquors.

The great concentration and consequent small bulk of the more highly polluting liquids produced in the woollen manufacture, also render feasible a method of disposing of them which would be utterly impracticable in the case of more dilute and voluminous foul waters, namely, by evaporation. Under even moderately favourable circumstances 1 lb. of coal will evaporate one gallon of water, consequently, in cases where the volume of the highly polluting liquids is known, the cost of thus disposing of these liquids is easily ascertained. In a case where the aggregate amount of such polluting liquor daily discharged is 240 gallons, the daily expenditure of 240 lb. of coal would entirely prevent such pollution. At the somewhat extravagant price, in many districts where this occurs, of 15*s.* per ton of coal, this most effective and simple mode of purification, or rather prevention, would cost rather less than 1*s.* 8*d.* per working day.

The method of evaporation is not recommended exclusively, however, but as an adjunct to other modes of purification, and especially in utilizing the waste heat from furnaces.

In the purification of refuse liquids by chemical agents, the principal operation at present conducted is the recovery of grease from the soapsuds produced in the washing operations of the woollen manufacture. But the Commissioners report that it is carried out in a very crude and imperfect manner. They consider that there are many well-known processes in technical chemistry which point to a much more effectual mode of separating these oily matters. A method suggested by them is, that after the addition of slight excess of sulphuric acid, the liquor should be briskly agitated with bisulphide of carbon, which would dissolve out the diffused minute oily globules in the form of an emulsion that would rapidly subside to the bottom of the vat, whence it could be drawn off into a still, and the bisulphide of carbon volatilized by a steam heat, condensed, and recovered for further use. At present the grease-extracting process is carried out only with a view to profit, and the so-called "purified" effluent water proved to be in all cases a most filthy and polluting liquid.

But the Commissioners consider that the best and most profitable mode of cleansing the foul liquids of woollen factories will be found in their application to land, and that their utility would be augmented by previously mixing them with several times their volume of town sewage. They also report favourably upon a system of intermittent filtration through porous earth, described in a former report, for the purification of sewage and the waste liquors from calico printworks and woollen factories.

After an exhaustive review of the information they had been able to collect, the Commissioners recommend (1.) That the casting of solid matters of whatever kind into rivers and running waters, or the placing where it is liable to be washed into the river by floods, be absolutely prohibited under adequate penalties. (2.) That the discharge of polluting liquids, which transgress certain limits, into any river or stream be prohibited under adequate penalties, a reasonable time being allowed for the execution of the necessary works for purification. (3.) That all rivers and streams in England be placed under the superintendence of a central authority or board, to be composed of not more than three persons, who shall be duly qualified to deal with all questions connected with the pollution of water and with water supply. (4.) That power be given to this board to inspect manufactories, reservoirs, sewerage, and other similar works; and to cause to be constructed, at the expense of the owners of the same, whether corporate or private, any necessary purifying apparatus, in case the said owners neglect or refuse to provide such apparatus for themselves. (5.) That, subject to proper regulations to prevent abuse, additional powers be given to corporations, local boards, manufacturers and others, upon compensation being made, to take land compulsorily, under "provisional order," for the purpose of cleansing sewage or other foul liquids. (6.) That it be the duty of the central board to exercise a surveillance over both the quality and quantity of the water supply of towns. (7.) That it be the duty of this central board to investigate all schemes for water supply; and also all proposals for public works connected with river conservancy.

It is also recommended that the following liquids should be deemed polluting and inadmissible into any stream:—

(*a.*) Any liquid containing, *in suspension*, more than 3 parts by weight of dry mineral matter, or 1 part by weight of dry organic matter in 100,000 parts by weight of the liquid.

(*b.*) Any liquid containing, *in solution*, more than 2 parts by weight of organic carbon, or ·3 part by weight of organic nitrogen, in 100,000 parts by weight.

(*c.*) Any liquid which shall exhibit by daylight a distinct colour when a stratum of it one inch deep is placed in a white porcelain or earthenware vessel.

(*d.*) Any liquid which contains, *in solution*, in 100,000 parts by weight, more than 2 parts by weight of any metal except calcium, magnesium, potassium and sodium.

(*e.*) Any liquid which, in 100,000 parts by weight, contains, *whether in solution or suspension*, in chemical combination or otherwise, more than ·05 part by weight of metallic arsenic.

(*f.*) Any liquid which, after acidification with sulphuric acid, contains, in 100,000 parts by weight, more than 1 part by weight of free chlorine.

(*g.*) Any liquid which contains, in 100,000 parts by weight, more than 1 part by weight of sulphur, in the condition either of sulphuretted hydrogen or of a soluble sulphuret.

(*h.*) Any liquid possessing an acidity greater than that which is produced by adding 2 parts by weight of real muriatic acid to 1000 parts by weight of distilled water.

(*i.*) Any liquid possessing an alkalinity greater than that produced by adding 1 part by weight of dry caustic soda to 1000 parts by weight of distilled water.

CREASOTE PILLS.

The following formulæ for the preparation of creasote pills are taken from the *Journal de Pharmacie et de Chimie*:—

Creasote	1 drop.
Soap Powder	0·25 gram.
Crumb of Bread	0·20 „
Lycopodium	0·05 „

For six pills. The soap powder forms with the creasote a homogeneous mass, to which the crumb of bread gives plasticity.

Or, better still—

Creasote	3 drops.
Crumb of Bread	0·60 gram.
Lycopodium	0·06 „
Mucilage of Gum Tragacanth	q. s.

For six pills, each of which will contain half a drop of the active constituent. In these proportions the manipulation is easy, and the appearance leaves nothing to desire.

IMPROVED STREET SURFACES.

The improved appearance of some of the leading City thoroughfares must be pleasing to the sight of sanguine sanitarians. The Poultry pure, Cheapside cleanly, Moorgate Street, Old Broad Street, London Wall muddy no more, and Lombard Street immaculate and free from dirt as the proverbial China orange, against which it has been so often pitted.

Asphalte and 'squeegee' have accomplished these desirable results, with the aid of the street orderly system introduced by Mr. Charles Cochrane twenty-five years ago, but which has made but little progress beyond the City walls, notwithstanding the sanitary advantages derivable from it.

Who would be 'jolted over the stones' if a smooth and noiseless road-surface was available? Stunned, bewildered and deafened by the din of the traffic in a granite-paved street, with what a sense of relief the pedestrian seeks refuge on asphalt! Merchants, bankers and tradesmen petition for peace and repaving, their prayers being as rapidly granted by the Commissioners of Sewers as economical considerations will allow.

Impermeable road surfaces of this nature present so many obvious advantages that it is to be hoped they may soon be largely extended through our Metropolis and provincial towns. The few drawbacks occasionally evident are not insurmountable; the slipperiness of surface apparent at certain times will, no doubt, be obviated as further experience is gained. The system is at present in its infancy, and the material used capable of considerable improvement; although up to the present time, notwithstanding the fact that twenty-seven asphalt paving schemes have recently been introduced, the Val de Travers and Limmer pavements are as yet unrivalled. —*Milk Journal.*

HULL CHEMISTS' ASSOCIATION ANNUAL SUPPER.

The Annual Supper of this Association was held on Wednesday evening, December 6th. Between forty and fifty gentlemen were present; the chair was occupied by Mr. Atkinson Pickering.

In replying to the toast of "Success to the Hull Chemists' Association," the Chairman alluded to the active part taken by the Association in opposing the Pharmacy Bill introduced during last session of Parliament. He considered that chemists and druggists, as a body, should make such rules and regulations for the management and governance of their own business as very varying circumstances required. One great object of the Chemists' Association was the establishment of a School of Pharmacy, and the security sought for was more likely to be obtained through such means than through any code of laws that could be devised by the Privy Council.

The toast of "The Medical Profession" having been drunk, Mr. J. H. Gibson expressed the pleasure it afforded him to visit the Society on such occasions. When first he came amongst them, there was a feeling almost of suspicion, at all events the profession had not the real confidence in the chemists and druggists which now existed between the two bodies. But by the organization that had taken place and the increased qualifications required from chemists and druggists before commencing business, their position had been much improved; and he believed that the feeling of confidence between them and the medical profession would grow and be an advantage to both. Some years ago it was a practice, and he must say a bad one, for chemists to prescribe over the counter. Even now, in cases of emergency, this might have to be done; he, therefore, hailed with satisfaction the advance that chemists and druggists had made in their knowledge of the virtues and properties of drugs.

SUNDERLAND CHEMISTS' ASSOCIATION ANNUAL DINNER.

The Annual Dinner of the members of this Association was held at the Crown and Sceptre Hotel, on Wednesday, December 6th. About thirty gentlemen were present. Mr. Alderman Thompson, President of the Society, occupied the chair. After the usual loyal toasts, Mr. J. J. Nicholson proposed "The Medical Profession," coupling the toast with the names of Dr. Abrath and Mr. George Welford, jun.

Dr. Abrath said he thanked them sincerely for the honour they had conferred on the medical profession. It afforded him great pleasure to meet the dispensing chemists; and he regretted that there was not more unity between the dispensing chemists and the medical practitioners of this town. He would like to see both professions on the same footing as they were in France and Germany. Here one robbed the other. Medical men had no right to dispense, and chemists had no right to prescribe. The law required to be altered, and if it was, he believed it would be for the benefit of both parties. He then alluded to the adulteration of drugs, and said that in France and Germany they were examined by Government inspectors, and the public were thus protected. It was the wholesale dealer who adulterated; and until this country reformed her laws with regard to drugs and medical men and dispensing chemists, she would remain the country of quackery.

Mr. Welford, jun., also replied, and said he agreed with Dr. Abrath as to each profession keeping to their own special sphere of labour.

The Chairman said he had spoken on this subject eighteen months ago, when, in his capacity of chief magistrate, he had dined with the medical gentlemen of the town, and he had at that time given expression to an opinion that there should be only one class of dispensers, and that they should be apart from the medical profession.

Mr. Turnbull gave "The Pharmaceutical Society of Great Britain," which was responded to by Mr. Sharp, who remarked that its members need never expect to secure the confidence of the medical profession, unless they took care to keep abreast of the intelligence of the day. He dilated upon the labours of the founder of the Society—Jacob Bell,—and the debt of gratitude that all classes of chemists and druggists owed to him and his fellow-workers.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 16, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE END OF THE BETTS SUITS.

A SHORT letter in our correspondence columns last week, from the solicitors who had charge of the defence to the Betts Suits, stating that Mr. BETTS had applied to have his Bill in the case *Betts* v. *Rimmel* dismissed, the costs to be paid by himself, records what is probably the last stage in this long and vexatious litigation. As this case and the twin case of *Betts* v. *Wilmot* at one time created considerable excitement among pharmaceutists, it will not be out of place to accompany this last act of the drama with a few remarks upon this glaring instance of the abuses possible in the present state of the law of patents.

The details of this dispute have so often been referred to in this Journal, that there is no necessity to repeat them here. The broad facts are that we have seen a patentee attacking a manufacturer for an alleged infringement of his patent,—the manufacturer not having made the article nor having a reliable test for distinguishing a capsule coated with tin by heat from one coated with tin by pressure; and even the patentee himself acknowledging that he could not tell one from the other.

Further, the patentee, not satisfied with getting his pound of flesh from the innocent manufacturer, pounced at the same time upon the customers of the latter, they being, if possible, still more blameless, and so sought his remedy from two sources.

But, fortunately, by dint of great exertions on the part of the defendants, the patentee was ignominiously defeated. He was forced to confess that he himself supplied the incriminated articles, which were made at his own house in Paris and sent by him to those who nearly became his victims.

And now the end of it all is, that the patentee simply withdraws from the prosecution, paying only the taxed costs, and justice is satisfied! But what is to compensate honest tradesmen for six years' anxiety from such wanton attacks? Why should one man have a right causelessly to inflict on another such losses in time, money and reputation?

We are glad to remember that the evil has been mitigated to some extent by the spirited and united manner in which the members of the trade concerned met the attack. The expenses of such litigation are very heavy,—we trust that, insatiable as Mr. BETTS appears to be, he will now be satisfied with his share of them,—and few tradesmen would have been prepared to incur the loss necessarily following even a successful defence. But had a system of compromise been generally carried out, the appetite no doubt would have been indefinitely sharpened by that which it fed upon. We, therefore, think that we may congratulate the defendants and the Defence Committee that—the necessity having arisen—the time and money employed by them have not been altogether thrown away.

PHARMACEUTICAL ETHICS IN NEW YORK.

AT a meeting of the New York College of Pharmacy on the 19th October, a "Code of Ethics" that had been drawn up was discussed and adopted. The greater part of this code is doubtless in accord with what is approved and carried into practice by most respectable pharmacists in this country, but we reproduce it for the purpose of illustrating the principles upon which our New York brethren aspire to have all pharmaceutical dealings in their city to be based, and the steps they are prepared to take to secure that object.

Preamble.—The members of the College of Pharmacy of the City of New York, considering it necessary that some mutual understanding should exist in regard to the moral principles guiding them in their profession, hereby agree upon the following Code of Ethics:—

1. We accept the U. S. Pharmacopœia as our standard and guide for all officinal preparations, and recognize a variance from its rules only in exceptional cases, where sufficient authority has proved some other process more reliable to attain the same end.

2. Although not a legitimate part of our business, custom and the necessity of the times warrant us in keeping on hand the patent medicines of the day; yet we earnestly recommend the propriety of discouraging their employment when called upon for an opinion of their merits.

3. We discountenance all secret formulæ between physicians and pharmacists, and consider it our duty to communicate such to each other when required.

4. We distinctly repudiate the practice of allowing physicians a percentage on their prescriptions; and we agree not to have a secret understanding with physicians to the pecuniary detriment of the public.

5. We will endeavour, as far as lies in our power, to refrain from compromising the professional reputation of physicians, and we expect the same comity from them.

6. Since the professional training of the pharmacist does not include those branches which enable the physician to diagnose and treat disease, we should, in all practicable cases, decline to give medical advice, and refer the applicant to a regular physician.

7. The growing demands of the age require that those who follow the profession of pharmacy should be educated up to a higher standard. Therefore, we consider it our duty, individually and collectively, to encourage the advancement of knowledge in our profession generally, and particularly by stimulating our assistants to attend the lectures of the College, and by aiding and assisting them to do so.

8. Considering it expedient that some rule be adopted to enforce the provisions of our code, we hereby agree,

if any just cause of complaint be found against a member of this College of having violated the rules or the spirit of our Association, to bring the case before a special or the next general meeting of the College, when the accused, after being heard in his own defence, may be expelled by a two-thirds vote.

THE CHICAGO COLLEGE FUND.

We are glad to be enabled to say that already the response to the appeal on behalf of the Chicago School of Pharmacy has been very favourable. The Committee has just issued a preliminary circular, and we purpose announcing the resulting subscriptions in our issue for next week.

We are informed by Professor Attfield that Dr. J. L. Soubeiran has written that he and his colleagues at the College of Pharmacy at Paris desire to contribute to the Fund, and that he will shortly forward a case of books to London for that purpose.

In consequence of the illness of H.R.H. the Prince of Wales, the Royal Society and the Society of Arts will not hold meetings next week. Mr. Collins's lecture on Economic Botany before the latter Society will be therefore postponed.

It is announced that the Great Exhibition of Arts, Manufactures and Science, at Moscow, will be opened on the 11th of June, 1872. The applications of persons desiring to become exhibitors must be made to the Committee of the Exhibition in Moscow before the 12th of January, 1872.

At a special meeting of the Board of Trustees of the Philadelphia College of Pharmacy, it was resolved that, should it be found impracticable to resume the lectures at the Chicago College of Pharmacy during the coming winter, matriculation tickets, and such lecture tickets as they may have paid for should be offered to the matriculants of the Chicago College, free of charge, for the present session.

In connection with the Philadelphia College also, a movement was recently set on foot to obtain the earlier closing of dispensing stores than heretofore. After several meetings and canvassing the city, the pharmacists of Philadelphia have resolved to close in future at 10 P.M., and a circular has been issued soliciting the co-operation of the public.

A decision having been recently obtained by the Parisian pharmaciens of the first class, to the effect that pharmaciens of the second class could not carry on business in Paris although holding diplomas granted by the Minister of Public Instruction upon the certificates of competency accorded by the professors and fellows of the École Supérieure de Pharmacie at Paris, an appeal was carried to the Court of Appeal of that city. The Court decided in favour of the Appellants, relieving them from the damages that had been pronounced against them in the lower court, and condemning the pharmaciens of the first class in the costs of the suit. It is stated that the pharmaciens of the first class intend to appeal to a higher court.

Provincial Transactions.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

An ordinary Monthly Meeting was held in the Memorial Hall, Albert Square, on Friday evening, December 1st; Mr. George S. Woolley in the chair.

Professor W. C. Williamson, F.R.S., delivered a very interesting lecture on "The Natural History of the Mineral Substances used in Medicine." The structure and probable mode of formation of various rocks, mineral veins, etc. were explained, after which, the Professor, aided by a splendid collection of mineralogical specimens, described the sources of the metals used in medicine. The attendance of associates was much larger than usual, and the lecture was listened to with evident pleasure and interest.

HALIFAX CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Annual Meeting of the Halifax Chemists and Druggists' Association was held on Thursday, December 7, 1871; Mr. Stott, President, in the chair.

After the minutes of last meeting had been passed, the Secretary read the report of the Committee for the past year, of which the following are the principal topics. Like other local societies, the Halifax Association had to regret a falling off in the attendance at the Latin and chemistry classes, and a lukewarmness on the part of apprentices to avail themselves of the means placed at their disposal for adapting themselves to the altered circumstances of the times. It was pointed out that the time may come when, if they persist in neglecting the opportunity in their youth, they will be weighed in the balance and found wanting. This is plainly shown by the large number of youths plucked by the examiners every quarter. The report urged upon members to impress upon their apprentices that youth is the best time for study, and to deprecate the bad policy of trusting to something turning up, and, probably, at the last having to make up for lost time by cramming. The possibility of the Pharmaceutical Society soon ceasing to be an educating body was referred to, and an opinion expressed that such an act would place more responsibility on local associations and individual chemists, if not make a total change in the apprenticeship system altogether. The Association had offered active opposition to the proposed poison regulations. The Committee respectfully called attention to the value and importance of chemists and druggists' associations, banded together for their trade interests and mutual good. Had the trade been as formerly, without any cohesion in the body,—nothing more, in fact, than a rope of sand,—it is not assuming too much to believe that the Poison Bill, introduced by the Government, would have been passed. It was anything but a pleasant sight to witness the manner in which the Council dealt with the poison difficulty; pitted and divided against itself, it failed to exercise any amount of influence for good on the right side, and it behoves them to consider whether they could look to the Council as their guide in the future. In conclusion, an appeal was made for continued support to the Association. Though thinly attended, the meetings had not been held in vain. They had rounded off a few of the many sharp corners and angles that protruded a little too far, and the mingling together had been the means of dispersing not a few doubts and jealousies that had existed.

Mr. Farr, in moving the adoption of the report, congratulated the Society on having reached its fourth year of existence, which showed that it was built upon a firm basis. He was very much pleased at the success of the recent early closing movement, and thought the thanks of the trade were due to the Committee if they had done nothing more than give them one hour more for study, recreation and social intercourse.

This resolution was seconded by Mr. Jessop, and carried unanimously.

Mr. Stott (Sowerby Bridge) was re-elected President, Messrs. Dyer and Farr Vice-Presidents, and Mr. Robert Brook, jun., Honorary Secretary.

The President then thanked the Society for the honour again conferred upon him, remarking that he believed he was the oldest in the trade in that part, and that he was one of the original four hundred that formed the Pharmaceutical Society. He regretted that so many failures occurred in passing the Preliminary, and strongly urged upon members that no apprentice should be indentured until he had succeeded in the first examination. He rejoiced that Government had not succeeded in carrying the Poison Bill, but warned the Society to keep a sharp look-out next Session of Parliament. He strongly objected to the principle laid down by Mr. Wilkinson, that of deviating from prescriptions, as being perfectly unjustifiable. This is a point of great importance that should be attended to, or great mischief might result. On the other hand, it is the bounden duty of the prescriber, as stated by the *Lancet*, to see that the proper and necessary quantities of ingredients are ordered to secure the end aimed at, and not compel the dispenser to seek an interview with the physician.

BRISTOL PHARMACEUTICAL ASSOCIATION.

A General Meeting of the Association was held on Friday, December 8, 1871; Mr. Townsend, President, in the chair.

The President announced his intention of shortly making a specific appeal to his fellow-members for subscriptions towards a fund that was being raised for the purpose of sending some help to the pharmacists of Chicago who had suffered sadly by the late calamitous fire. He would call upon Mr. Stoddart for the lecture he had kindly promised them, upon "Potable Water: its Importance and its Impurities."

Mr. Stoddart then delivered his lecture, of which the following is an abstract, and, at its conclusion, received a cordial vote of thanks:—

After touching upon the importance of the water question, the office of water in the animal and vegetable economy, its physical properties, and the sources of supply, the lecturer drew attention to some celebrated Bristol wells, such as Jacob's well, All Saints' well, the Quay pipe, etc. Having shown how rain percolated through the earth to the wells, he remarked that so long as there were no houses on the top of Clifton Hill, no doubt Jacob's well contained very good water, but supposing the houses above it on the hill should throw out refuse, nothing could save the well from being contaminated. He had known a case in Unity Street, where it was ascertained that several children had typhoid fever on account of drinking the water from a well which was below the level of the Float, and into which injurious matter from the Float had made its way. There were wells in St. Paul's, in a bed of sand, which extended several square miles ten feet below the surface of the ground. This substance was so porous that any liquid matter percolated through it very rapidly; and as there were two churchyards in the district, he had no doubt that if all the wells were examined which were sunk in that bed of sand, they would find some of the water was nothing but animal solution. The well at the end of Terrell Street, when it was in the garden of the monks of the priory, which stood where St. James's Church now stands, undoubtedly gave very pure water, but since Kingsdown had been covered with houses, the whole drainage of Kingsdown went into that well, and the water was not fit to drink. It was almost impossible to have pure water in a city from a well, because impure matter would sink down into the source of supply. There was a danger arising from our sewers, which was often overlooked,—the noxious gases which arose to the top of the pipes, and which made their way very often under pressure of the tide into houses, and generated disease. As a matter of fact, the top of the hill was not so healthy as the bottom, although it was generally thought the reverse was the case. Three years ago zymotic fevers were more prevalent on the higher ground than they were on the lower. They had in Bristol a splendid fall for the sewage, but the houses were built so as to take the greatest care of these gases, and the wonder was the inhabitants were not all poisoned. One or two places in Bristol had actually been built with ventilating shafts, so that the gases could escape, and this should be the case in all houses to prevent the gases poisoning the air. That morning he had been astonished at reading that the Prince of Wales had been drinking Bristol water. He had seen in the *Times* a most exhaustive report upon the water of Scarborough and the neighbourhood. He found also that Lord Londesborough had been in the habit of using the Bristol water—the water from the Hotwells pump. More than that, an analytical chemist, having examined the Scarborough and other waters, found the Bristol water splendidly wholesome, the only water of the whole that was wholesome. That was admitted in the *Times* of that morning. Many persons might say that the illness of the Prince of Wales had been caused by the Bristol water; but if they read the report he had alluded to, they would find that the illness was undoubtedly caused by the gases which escaped from the sewers. The report was very plain and unmistakable on that point. Mr. Stoddart, referring to the water supplied by the Bristol Water Works Company, said they could not be too thankful for it. According to the report of the commission on the water of the United Kingdom, there was no better water, take it altogether, than that supplied by the Bristol Water Works. It came in hermetically-sealed pipes, into which no sewage could penetrate, from splendid reservoirs. The water was as pure as the water from the much-vaunted chalk wells of the East of England, and was as free from impurity as water could possibly be. The lecturer alluded also to the fallacy of popular tests, and showed that appearance and taste were not to be trusted; and concluded by drawing various sanitary deductions. The lecture was illustrated by specimens, photographs and diagrams, shown by the oxycalcium light.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

Dyes and Dye-Stuffs other than Aniline.*

BY DR. CRACE-CALVERT, F.R.S.

Lecture III.

Blue Colouring Substances.—Indigo, Orchil, Cudbear, Litmus, Prussian Blue and Ultramarine.

Indigo.—This most valuable dyeing substance was used as a dye-stuff in India and Egypt long before the Christian era, and the Romans were acquainted with it, although they only used it as a pigment, not knowing how to render it soluble, and so available for dyeing. It is only since the sixteenth century, or from the time of the discovery of the passage to India round the Cape of Good Hope, that it has become generally known in Europe; and its employment as a dye was greatly retarded by the opposition it met with from the large vested interests of the woad cultivators, who induced the English, French and German governments to pro-

* Cantor Lecture, delivered Tuesday, Feb. 21. Reprinted from the *Journal of the Society of Arts*.

mulgate several enactments against its use. So severe were some of them, that Henry IV. of France issued an edict condemning to death any one who used that pernicious drug called the "devil's food." It is only since the year 1737 that the French dyers have had the right of using indigo without restriction.

Indigo exists in several varieties of plants, among which may be mentioned the *Polygonum tinctorium* and the *Isatis tinctoria*, or woad; but, as in the case of nearly all the dye-stuffs already spoken of, it is found most abundantly in plants of the leguminous order. It is extracted commercially from the genus *Indigofera*, varieties of which grow abundantly in India, Java, China and in some of the South American States.

To extract the indigo which the plant contains, it is mowed when in full flower, made into bundles, and carried into large vats containing water. Fermentation ensues, which is allowed to proceed for eight or nine hours, when the liquor, which was yellow at the beginning of the operation, assumes a dark green colour, forming a blue scum on the surface. This liquor is then run off into shallow vats, where it is violently agitated with sticks, stirred by men or women, or with a dasher, which produces the same result, the conversion of the white soluble indigo into blue insoluble indigo. A little lime-water is now added, and the whole allowed to rest. The blue indigo thus deposited is boiled with water, when a scum, composed of vegetable and animal matters, comes to the surface and is removed. The blue paste is thrown on a filter, pressed and placed in wooden frames, which are divided into small squares, where the indigo is allowed to dry first in the sun and afterwards in the shade. The quality of the indigo produced depends mainly on the care bestowed on its manufacture.

Until 1855 we had no correct ideas as to the state in which the indigo existed in the *Indigofera* plants, nor of the changes which it underwent during the process of extraction. It had been stated by M. Chevreul, many years before, that white indigo was oxidized into blue. But in the above year, and subsequently, in 1857 and 1865, Dr. Schunck published a series of papers, in which he described the true nature of the chemical changes which take place in the manufacture of indigo. He operated on the *Isatis tinctoria*, or woad, which contains the same colour-giving principle as the *Indigofera*, and is the only plant yielding indigo that grows freely in this country.

By these researches he demonstrated that indigo existed in the plants, combined with a sugar, forming a glucoside, to which he gave the name *indican;* this compound, under the influence of fermentation in the manufacturing process, was unfolded into indigo and sugar. By treating the dried woad with ether or alcohol, Dr. Schunck obtained indican, and, among other processes for its extraction, gives the following simple one. He treats the pounded dried woad leaves with ether in a displacement apparatus, and distils off the greater part of the ether. The remaining green liquor is then evaporated at a moderate temperature, a little cold water added to the syrupy residue, and the insoluble chlorophyl and other matters separated by filtration. The yellow liquid thus obtained is evaporated, either spontaneously or in vacuo.

Indican is a yellow, transparent, glutinous solid. As may be seen from the above, it is soluble in alcohol, ether and water. When boiled with caustic alkalies it evolves ammonia, but its most remarkable and interesting property is that of yielding indigo blue when treated with strong acids. If sulphuric or muriatic acid be added to its water solution, no change whatever is perceptible for some time; but on heating to near the boiling-point, the solution immediately becomes sky-blue. On boiling for a short time, the solution becomes opalescent. On continuing to boil it acquires a purple colour, and then, provided the solution is tolerably concentrated, a copious deposit of dark purple flocks is formed. These are collected on a filter and washed with water. By treating the washed flocks with alcohol, Dr. Schunck obtained pure indigotine, and a reddish-blue substance was dissolved, called by Berzelius indigo-red, and by Schunck indirubine, which may be considered as a product of the decomposition of indican.

The colour-giving principle of the plant may be considered, like those of the dye-woods, as a glucoside, yielding by its decomposition a colourless principle, which is afterwards converted into a colour. Dr. Schunck explains by the following formula the decomposition of indican into indigo:—

$$\underset{\text{Indican.}}{C_{26}H_{33}NO_{18}} + \underset{\text{Water.}}{H_2O} = \underset{\text{Indigo.}}{C_8H_5NO} + \underset{\text{Indiglucine.}}{3(C_6H_{10}O_6)}.$$

In 1864 he published a most valuable paper, throwing much light on the manufacture of indigo, and the management of what is called a woad vat. In it he gives the chemical actions which take place, and explains why, if the indigo manufacturer does not take the greatest care in conducting the process of fermentation, to extract the indigo from the plant, he will either get an inferior quality of indigo, or a great decrease in the yield of the product, or even in some cases entirely lose the colouring matter. He shows that these results take place when the fermentation in the vats is allowed to be either too rapid or too prolonged, in which cases not only is indican decomposed, but the *indiglucine*, or sugar, is converted into alcohol and acetic acid; and he shows that the indigo combines with this alcohol and acetic acid, yielding a compound which does not permit the indigo it contains to be oxidized on exposure to the air. This explains the loss of indigo in its manufacture. Dr. Schunck represents the change by the following formulæ:—

$$\underset{\text{Indigo.}}{C_8H_5NO} + \underset{\text{Alcohol.}}{8(C_2H_6O)} + \underset{\text{Acetic Acid.}}{3(C_2H_4O_2)} + CO_2$$
$$= C_{31}H_{39}NO_4 + 13H_2O.$$

He produced this compound more easily by treating pure indigo blue with alcohol, to which was added an alkaline solution of protoxide of tin, until the indigo was dissolved, acetate of soda was then added, and the whole digested at a moderate temperature. The indigo blue after some time ceased to be deposited on exposure to air, having entirely disappeared, and been converted into the new compound.

Pure indigo, or indigotine, can be prepared from indican, by the process already described, or by reducing indigo to powder, placing it in a small dish on which is a cover, and applying a heat of about 300° or 400° F., when beautiful prismatic needles of indigotine are sublimed, which are removed mechanically. It is insoluble in water, alcohol or ether, or in weak acids or alkalis, but is slightly soluble in creasote, carbolic acid, and anhydrous acetic acid, to which a very small quantity of sulphuric acid has been added. From this latter solution, the indigotine may be precipitated by the addition of water. It is the only solution of blue indigo that can be applied directly on a fabric.

Indigotine, when heated, gives off beautiful violet vapours, having a characteristic odour. Under the action of oxidizing agents, such as nitric acid, it yields three distinct products, *isatin*, $C_8H_5NO_2$; *indigotic* or *nitrosalycilic* acid, $C_7H_3(NO_2)O_3$; and picric acid, $C_6H_33(NO_2)O$. The first is formed by simple oxidation, whilst in the second and third, part of the carbon is oxidized, and hyponitric acid is substituted for part of the hydrogen. These chemical reactions lead me to call your attention to some very interesting scientific deductions, showing indigo to bear a very close relation to aniline and carbolic acid, both products derived from coal-tar. If indigotine is heated with potash in a small retort, aniline is produced, and distils over. When indigo is heated for some time with caustic potash solution of sp. gr. 1·35, it yields anthranilic acid, which may be considered as a phenyle-carbamic acid. Anthranilic acid again, being heated to 570° F., gives salycilic acid, which may be considered as a compound of carbonic with carbolic acid. Lastly, indigotine, like carbolic acid, yields on treatment with excess of nitric acid, picric or trinitrophenic acid.

These facts have produced on the minds of chemists a conviction that indigotine will one day be artificially prepared from carbolic acid, and recently MM. Emmerling and Engler have accomplished the scientific artificial production of indigotine from a compound acetone, discovered in 1857 by M. Friedel, to which these gentlemen have given the name of acetophenone. Their process consists in acting on this compound with fuming nitric acid, when two nitro-compounds are produced, one crystalline, the other syrupy. To the latter, after its evaporation to the state of a resinous mass, they add ten parts of reduced zinc and one part of soda-lime. The mixture is heated in small tubes, when a little water evaporates, and a dark-coloured substance sublimes, which contains indigotine in small quantities. This result is certainly a triumph of scientific chemistry, and brings us another stage nearer the commercial artificial production of a most valuable dye.

A great variety of substances, by adding one equivalent of hydrogen, convert blue indigo into white indigo, which is a colourless substance, without taste or odour, insoluble in water, but soluble in alcohol and ether, and in solutions of the alkalis and alkaline earths. On this point I may observe that, many years ago, I devised a process by which many pounds' worth of indigo were recovered from the refuse bottoms of the blue dip vats, the preparation of which I shall explain further on. I found that indigo was susceptible of forming insoluble compounds with the lime and protoxide of iron. White indigo dissolves freely in strong sulphuric acid, giving a dark purple-blue liquor.

Many substances are employed commercially to convert blue indigo into the white indigo soluble in alkalies. Thus, I may mention lime and protoxide of iron, caustic alkali and protoxide of tin, or sulphuret of tin or arsenic, and zinc and caustic alkali; also organic substances, such as grape sugar and bran, which enter easily into fermentation. The following formulæ show the difference of composition of the two indigos:—

$$\underset{\text{Indigotine.}}{2(C_8H_5NO)} + \underset{\text{Hydrogen.}}{2H} = \underset{\text{White Indigo.}}{C_{16}H_{12}NO_2}.$$

I shall now have the pleasure of proceeding to describe some of the methods employed by chemists to determine the relative commercial value of samples of this expensive dye. The best qualities of indigo from Bengal, Java and Guatemala are light, have a uniform texture, and a fine coppery hue, which is increased by friction. The following analysis, made by M. Chevreul, shows the composition of a fair sample of commercial indigo:—

Indigotine	45
Matters soluble in alcohol	30
Matters soluble in ether	12
Resin soluble in hydrochloric acid	6
Mineral matters	7
	100

Commercial indigos are often adulterated with mineral matters of various kinds. This fraud is easily detected by calcining a known weight of the sample, which ought not to leave a residue of more than 10 per cent. The most common adulteration, however, is the addition of starch. This can be detected by boiling some of the pulverized indigo with a weak solution of hydrochloric acid. The insoluble starch is thus converted into soluble dextrine, which yields a beautiful purple colour with iodine.

There are several processes employed to determine the amount of indigotine in commercial indigos. I shall here only give the outline of three. The first consists in dissolving one gramme of the dry pulverized indigo in twelve grammes of concentrated sulphuric acid, and heating the whole at a temperature not exceeding 120° F., when the indigo combines with the sulphuric acid, and becomes perfectly soluble in water. It is then diluted with water, so that the whole occupies one litre. The operation is repeated with one gramme of pure indigotine, which serves as a standard of comparison. A solution of bleaching powder, or bichromate of potash—the first proposed by M. Chevreul, the latter by Dr. Penny—is prepared of such a strength that one hundred volumes of the solution will completely destroy the whole of the colour produced by the gramme of indigotine. Part of the same liquor is then applied to the solution of the commercial indigo, and the number of volumes required to destroy the colour represents the percentage of indigo. Thus, if 60 divisions are required, it is assumed that there is 60 per cent., if 70 divisions, 70 per cent. This method of estimating the indigotine is not to be relied on, as it always gives a much higher percentage of colour-giving principle than exists in the indigo, owing to the hypochlorous acid of the bleaching-powder, and the chromic acid of the bichromate not only decomposing the indigotine, but acting on several colouring matters which are included in the portion soluble in alcohol in M. Chevreul's analysis.

The second process gives better results; it is due to Professor Fritzsche, and consists in introducing one part of indigo, finely pulverized, and one part of grape sugar, into forty-eight or fifty parts of boiling alcohol, to which are added two parts of a concentrated solution of caustic soda. The whole is put into a bottle exactly large enough to hold it, and left to cool. By exposing the colourless liquid to the atmosphere, the reduced indigo which is in solution absorbs oxygen, and the indigotine is precipitated under the form of beautiful prismatic crystals.

The third process, devised by myself, I have found to give satisfactory results. It consists in introducing into a flask one part of finely pulverized indigo, two parts of green copperas, and two hundred parts of water containing 10 per cent. of caustic soda. The whole is kept at the boil for a short time, and allowed to cool. The clear liquor is exposed in shallow vessels to the atmosphere, when the soluble indigo is oxidized, and precipitates as pure indigotine. The residue in the flask is submitted to the treatment three times. The whole of the indigotine thus obtained is collected on a filter, dried, and weighed.

A commercial process, founded on the above method, is carried on by Messrs. Haas and Co., who sell indigo so purified under the name of refined indigo. An inferior quality is also prepared by heating indigo, at a moderate temperature, with weak muriatic acid, which dissolves lime and other mineral matters, as well as any starch it may contain; it is slightly washed and boiled with weak caustic soda, to dissolve the chlorophyl and other resinous impurities.

I shall now call your attention to three commercial preparations of indigo, obtained by the action of sulphuric acid on it. The first is called *sulpho-purpuric acid* or *phenicine*, which is made by adding one part of indigo to four parts of highly concentrated sulphuric acid, heating for a short time, varying from half an hour to an hour, or until a small quantity of it mixed with a large quantity of water gives a deep purple colour. Great care must be bestowed on this part of the operation, so as to avoid the formation of a compound, to which I shall have again to call your attention, *sulpho-indigotic acid.* The acid mass produced is thrown into about 40 or 50 parts of water, when a beautiful purple precipitate is produced, which is collected on a filter, and slightly washed with weak muriatic acid. To dye wool with this sulpho-purpuric acid it is necessary to add to the bath a little muriatic acid, when it yields to the wool a fine dark purple-blue, that can be converted into various shades of purple by passing the wool so dyed in a bath containing a small quantity of carbonate or acetate of soda, which removes a small quantity of sulpho-indigotic acid that may be present, and gives rise to *sulpho-purpurate of soda*, which is a faster dye than the acid.

Sulpho-indigotic Acid is manufactured by dissolving one part of indigo in ten or twelve parts of concentrated sulphuric acid, and heating the whole at a temperature of 120° F. very carefully for some hours. The operation is completed when a small quantity dissolves entirely in cold water.

The acids above described, when obtained perfectly pure, have the following formulæ:—Sulpho-purpuric acid, $C_{16}H_{10}N_2O_2, SO_3$; sulpho-indigotic acid, C_8H_5NO, SO_3.

Berzelius admits a third compound, called *hypo-sulpho-indigotic acid*. These acids are transformed into neutral salts of soda, and sold under the names of neutral paste and carmine of indigo. They are prepared by neutralizing the sulpho-acids with carbonate of soda, and the paste so formed is thrown on a woollen filter to remove the sulphate of soda which it contains, as well as a green colouring matter, which is doubtless modified chlorophyl. The paste is then washed with a solution of chloride of sodium. It is a curious fact that carmines of indigo, which are perfectly soluble in pure water, are altogether insoluble in water containing either sulphate of soda or chloride of sodium.

Whilst speaking of the sulpho-indigotates, it may be useful to notice that the sulpho-indigotates of potash and soda are soluble in 100 to 150 parts of water, the sulpho-indigotates of lime, magnesia, and alumina are freely soluble, whilst those of baryta and lead are insoluble.

(*To be continued.*)

Parliamentary and Law Proceedings.

Prosecution of a Chemist for Misrepresentation.

Dalrymple *v.* Lakin.

In this case the defendant had been summoned before the Leicester magistrates, under the Medical Act, for having illegally practised as a doctor of medicine.*

On Friday, December 1, at the request of the Mayor, the judgment of the Bench (which went fully into all the facts of the case) was read, the substance of which was as follows:—"In the case now before us, it appears that the words 'Dr. Lakin' are on a plate at the side of the door; that the words 'Dr. Lakin, botanic practitioner,' are over the window in large letters, extending the whole length of the front of the house; that the defendant is in possession of an American diploma; and that in a certificate of death he describes himself as 'M.D. (U.S.).' With respect to this certificate, we think no one can successfully contend that a person who actually describes himself as M.D. (U.S.)—evidently meaning a doctor of medicine of the United States—is guilty of the offence of wilfully and falsely assuming the title of doctor, so as to imply that he is a recognized physician in England; and the words 'botanical practitioner' would probably be viewed in the same light as 'mechanical dentist' were in *Ladd* v. *Gould*, as they do not appear to be such words as would be used by any medical man who wished it to be known that he was a legally-qualified practitioner, and registered under the Act. Although we could have wished that the facility with which foreign diplomas are obtained, and their utter worthlessness in many cases as tests of medical proficiency, had been more fully brought under the notice of the Court of Exchequer, yet, after the decision in *Ellis* v. *Kelly*, which opened the door for the admission of foreign diplomas for the purpose of negativing the charge of a false pretence, and the view of the right to use the word 'doctor,' taken even in a work regarded as one of the organs of the medical profession, in which it is broadly stated that a person in the possession of the degree of M.D. under a diploma from the College of Pennsylvania, however obtained, has the right to call himself a 'Doctor of Medicine' if he pleases (see *Lancet*, September 23, 1871, p. 457),—we do not feel justified in convicting the defendant of the serious offence of having by 'wilful falsity' used the title of doctor, he being in possession of a diploma from an incorporated college in the United States, which has the appearance of being, although not legally proved to be genuine; as the possession of such a document may have led the defendant to believe, in common with some members of the medical profession in England, as shown by the publication to which we have referred, that he was entitled to use the prefix of 'Dr.' to his name, and this may under a penal statute be an answer to the charge of having 'wilfully and falsely' assumed such title. We think it will not be out of our province to add that if the Medical Act were intended to give any security to the public that medical practitioners should be persons of education and science, it has to a great extent failed in its object; and that to be effectual it requires material amendment, as the offence created by the Act is not that of practising without being registered,—for which there is no penalty,—but of wilfully and falsely using a name or title implying that the party has been registered, an offence which, considering the interpretation put on the words 'wilfully and falsely' in the cases referred to, it is exceedingly difficult to prove in a court of law."

* See *ante*, p. 457.

Action for Recovery of Apprenticeship Premium.

Court of Common Pleas, Westminster, Dec. 4.

Before Mr. Justice Byles and a Common Jury.

Fowler *v.* Curtis.

Mr. D. Seymour, Q.C., and Mr. Collins were counsel for the plaintiff; Mr. Serjeant Parry and Mr. J. O. Griffiths for the defendant.

This was an action to recover damages for a breach of covenant in an apprenticeship deed. The plaintiff was apprenticed to the defendant, a chemist, druggist and dentist in the Haymarket, for the term of three years and a half. Towards the close of the first year the defendant became unwell, and was advised to dispose of his business, which he did, and was consequently unable to continue to instruct the plaintiff in the art and mystery of the profession. The defendant paid into Court the sum of £130, part of the premium of £170 received from the plaintiff, retaining £40 for the instruction and other benefits received during the first year of the term. The plaintiff was dissatisfied with this, representing to the jury that the first year's instruction was little more than the drudgery of minding the defendant's shop from early morn to late at night.

The jury found that £130 was insufficient, and gave to the plaintiff £40 more,—in effect, finding that the plaintiff was entitled to the return of the entire premium.

Suspected Poisoning.

On Tuesday, Dec. 4th, an inquest was held at Hoxton, to inquire into the circumstances attending the death of William Dent Russell, aged seven months.

Amelia Russell, wife of William Russell, a cabinet-maker, said that deceased was her son. He had a cough for some time past, and she often gave him some mixture which she had obtained from a chemist. After administering some of it to the child on Thursday, he became suddenly ill, and died at four o'clock on Friday morning in great agony. Her husband was very unkind to the deceased, and often said he wished it was dead. Her husband used oil of vitriol in his business.

Mr. Walter Rumbold, M.R.C.S., said he had made a post-mortem examination of the body, and found that the lips, mouth, throat and stomach were shockingly burned by sulphuric acid (oil of vitriol), and death was the result of poisoning from such acid.

William Dent Russell, the father, made the following statement:—I use oil of vitriol for lime-light. I last used it six weeks ago. I kept it in the coal-cellar. I was tipsy on Monday, but on Tuesday, Wednesday and Thursday was sober. I work for Sanders and Co., of Oxford Street. I cannot account for the death of the deceased.

The Coroner, addressing the jury, said that it would be better to adjourn for further inquiries to be made. It certainly appeared as if the acid had been put in the bottle by design, and the evidence given tended to show that the father wished to get rid of the poor infant. The case accordingly stands adjourned for further evidence. —*Daily Telegraph.*

Reviews.

RESOURCES OF THE SOUTHERN FIELDS AND FORESTS, MEDICAL, ECONOMICAL AND AGRICULTURAL; being also a Medical Botany of the Southern States; with Practical Information on the Useful Properties of the Trees, Plants and Shrubs. By FRANCIS PEYRE PORCHER, M.D., formerly Surgeon in charge of City Hospitals, Charleston, Lecturer on Materia Medica and Therapeutics, etc. New edition. Revised and largely augmented. Charleston: 1869. Trübner and Co., London. Post 8vo, pp. xv. 733.

It is an old saying and a very true one, that "necessity is the mother of invention." It often occurs that when a source of supply fails, we turn our eyes nearer home, and find almost at our feet that which, but for the foreign supply failing, we should have overlooked. But let us explain what this has to do with the book before us. When the Southern States of America declared a war of independence, as a necessary result all their ports were blockaded and their foreign supplies cut off. The Southern authorities, fully appreciating the varied and rich flora by which they were surrounded, instructed Dr. Porcher to use his best efforts to find substitutes for the foreign vegetable products, applicable to the wants of the surgeon as well as to the planter and farmer. For this duty our author was the better qualified, inasmuch as, for a period of twelve years previously, he had paid great attention to the subject, and had practically tested many of the substances he enumerates. The results of his labours are here given, and the book is intended as a handbook of scientific and practical knowledge as regards the medical and economical products of the plants of the Southern States, and capable, if need be, to serve present or future wants, thus rendering them, in a great measure at least, independent of foreign supplies.

The author only claims for his book the title of a compilation; but though this is the case to a great extent, yet he has spared no pains to render it as complete as possible, extending his note taking from the pages of Ray, Culpepper, Thornton, Woodville, Lindley, Royle, Pereira, and Merat and De Lens, to the latest floras and local plant catalogues. Under each plant he gives a copious list of authors, to whom reference can be made for fuller information. The articles which meet with the fullest notice are the seven staple articles, viz. cotton, rice, sugar, tobacco, wheat, corn and turpentine, as also those more or less likely to figure largely, as grapes, wine, sorghum sugar, tea, esparto, flax, mustard, castor and other oils, starch-yielding plants and timber and furniture woods. Cryptogamous plants are dealt with somewhat curtly, the author giving, as his reason for so doing, a previous publication of his, which appeared in the seventh volume of the 'Transactions of the American Medical Association.'

The information is arranged in Natural Orders. This naturally leads to many cross-references; and though, perhaps, on the whole, as good an arrangement as any, yet we should not have been sorry to have seen an attempt at grouping, under good headings, the various substances according to their properties; as in a book such as this, destined for general use, the latter arrangement would have appealed more to the sympathies of unscientific readers. The author gets over the difficulty by treating certain substances at length under the plant characteristically rich in such products. Thus under the oak and hickory we have an account of potash and potash soap and their manufacture; under salsola and fucus, soda and soda soap; under pine and willow, an account of charcoal; and oils in general, under *Sesame.* This is the name given to the seeds of *Sesamum indicum.* The author gives an account of this plant under the trivial name *Bene.* This is to be regretted, as it more properly belongs to *Moringa pterygosperma*, and in Europe is so understood. In justice, however, we may state, that so far as we have examined it, the index is a very trustworthy and ample one. Under *Papaver*, we have a long account of the manufacture of opium. *Argemone mexicana*, an almost cosmopolitan plant, the oil of whose seeds has been highly recommended by some as a specific in cholera, is not highly spoken of. The root of *Panax quinquefolium* is valued for its stimulant, stomachic and tonic properties. It meets with a ready sale in China, being much cheaper than that of *P. ginseng*, a Chinese imperial monopoly.

Thea viridis, grown in South Carolina, is well spoken of. Oranges, limes and citrons are cultivated in the warmer regions.

The fruits of *Stillingia sebifera* are largely used in candle making. In the account of the American indigo plant (*Baptisia tinctoria*), tinctorial plants and dyeing are treated generally. The bark of the root of *Robinia pseudo-acacia* is recommended as a tonic in large doses; it is emetic and purgative, and the inner bark is recommended as a source of fibre, the seeds as oil, the flowers as a yellow dye, and the wood for shipbuilding. Under *Anacardiaceæ*, the account of the poison oak (*Rhus toxicodendron*) and shumac (*R. glabra*) are very interesting. The leaves of *R. copallina* were used by the soldiers in camp to increase the bulk, and render milder, ordinary tobacco. Sassafras tea, as a substitute for green tea, was a great favourite with the Southern States' officer during the war. In *Sarracenia* the author has no confidence as a specific in smallpox. Under another well-known plant, *Sanguinaria canadensis*, references are given to no less than twenty-five writers on the subject. The leaves of *Opuntia vulgaris* are used for hardening candles instead of wax. There is also a good account of *Acer saccharinum*, and the manufacture of the sugar from it. The seeds of *Æsculus pavia*, L., contain much starch, and the washings of it are very narcotic; ten grains of the powdered rind being considered equal to three of opium, and the roots are preferred to soap for washing and whitening woollens, blankets and dyed cottons. Under the head of *Linum usitatissimum*, oils are treated of generally. *Hibiscus esculentus* is spoken of as being twice as mucilaginous as *Althæa*, and of great uses in culinary and medical preparations; the seeds roasted are used as a substitute for coffee, and are also used on account of their albumen in clarification in St. Domingo.

Rice, formerly at least largely grown in Carolina, meets with a very full account. Since the war little or no Carolina rice has been exported to this country. That which commonly passes under that name now is produced in Berbice. We may mention, though the fact is not noticed by our author, that Carolina is believed by some to have owed the introduction of her rice to Madagascar; certain it is that the varieties are remarkably alike.

The trivial or vernacular names are appended to the plants, in many cases identical with those given in other countries to widely different plants, thus showing the necessity in quoting a native name, to append the name of the locality or country in which it is used. Nothing is more natural than for a person leaving one country, with its scenes and associations vividly impressed on his mind, on arriving in a new one to endeavour to perpetuate these associations by naming the surrounding objects in accordance therewith. By reference to the index we find from thirty to fifty plants are mentioned as alteratives, antiperiodics, aromatics, astringents, cathartics, diuretics and narcotics.

But here we must draw our lengthy notice to a close. Though events happily have not driven the Southern States to the dire necessity of finding in their own area all the supplies for the real and artificial wants of their inhabitants, yet the information cannot but prove of value. Though the book is not original, yet the author has brought together, in an available form, the scattered literature of the subject, and has not failed to indicate his authorities,—a virtue, sad to say, regarded as somewhat antiquated, the work of the clever paraphrast passing often as original.

The Chemists and Druggists' Diary and Pharmaceutical Text-book, 1872. London: 'Chemist and Druggist' Office.

A "sign of the times" has reached us in the shape of the annual issue of this useful book. As this is the fourth occasion upon which the publishers have provided a diary specially prepared to meet the convenience of chemists and druggists, it is only fair to infer that the speculation in past years has been a successful one. We venture to predict that the present will be no less so, and that many more times the 'Chemists and Druggists' Diary' will appear with the fogs, frosts and snows of the closing year to help to supply our wants in the new one.

In one respect, at least, the Diary just published is an improvement upon its predecessors: the size of the page is doubled. This alteration, although not going quite as far as our suggestion last year, allows a much larger space for each day's entries. In the pages set apart for literary matter the principal feature this year is a collection of pharmaceutical formulæ of compounds, Continental in their origin, but frequently demanded from the pharmacist in this country. They are arranged under the respective headings of "France," "Prussia," "Austria," "Saxony," "Russia," and "Denmark, Norway and Sweden." These formulæ have been compiled by Messrs. Joseph Ince and S. W. Rich, of London; F. Froedman, of St. Petersburg, and H. Fölker, of Dresden. As we have a guarantee that no formula is given that has not been frequently used by the writer himself, there is here, doubtless, a great quantity of valuable information brought within a small compass, though we are inclined to doubt the propriety of classing some of it under the respective countries. For instance, there does not appear to be anything peculiar to the formula for "foie de soufre," or "liver of sulphur," that may not be found in the potassa sulphurata, B.P. The ingredients are the same in the same proportions, and the manipulation does not appear materially to differ. Under the heading "United States," are given a list of all the preparations of the U. S. Pharmacopœia, which have no direct representatives in the B. P., and a list of differences in the preparations which are common to both Pharmacopœias.

Among the other matter specially interesting to pharmacists, we may mention abstracts of Acts of Parliament likely to affect them;—a "Table of Maximum Doses," and an "Approximate Table of Solubilities." Solubilities have frequently given rise to difference of opinion, and the word "approximate" gives a certain amount of latitude: but we think this is overstepped in some cases in this table, *e. g.* when the solubility of acetate of potash in cold water is given as one part of the acetate in two of water.

The Diary is published in two forms, one being interleaved with blotting paper and in superior binding. Besides the subjects mentioned above, it contains a fair quantity of the information usually accompanying almanacks.

Obituary.

PROFESSOR SPOONER.

It is with regret that we have to announce the death of Professor Spooner, who for many years occupied the most prominent position in the veterinary profession. Professor Spooner entered the Royal Veterinary College as a student in the year 1828, and after attending the then limited course of study in that institution, obtained the diploma entitling him to practise as a veterinary surgeon. He afterwards established classes for private instruction outside the College walls, and conducted them with great success for about nine years. During a part of this period he held the post of veterinary surgeon to the Zoological Society. The first collegiate appointment he received was that of Demonstrator of Anatomy to the Royal Veterinary College, and after passing through the grades of Deputy-Professor and Professor, he ultimately rose to the position of Principal. This last office he held for eighteen years, and until he died of disease of the heart on the 24th ult., Professor Spooner was a most eloquent lecturer as well as a clear expositor of veterinary science, and to him a large proportion of the present generation of veterinary surgeons are indebted for much of their professional education. As a witness in cases of veterinary jurisprudence few, if any, could equal him; and from his great and varied experience, his testimony and opinion were highly valued by judge, jury and client. Professor Spooner became President of the Royal College of Veterinary Surgeons in 1858; he was also a member of council, and an *ex officio* member of the board of examiners. By many his loss will be keenly felt, for they will be deprived of a sound professional adviser and a staunch friend.

MEETINGS FOR THE ENSUING WEEK.

Monday, Dec. 18. ......*Medical Society*, at 9 P.M.
London Institution, at 4 P.M.—"Locomotion, Voice and Speech." By Professor Huxley. (Educational Course.)

Thursday, Dec. 21. ......*Chemical Society*, at 8 P.M. "On Eulyte and Dyslyte." By H. Bassett.
Linnean Society, at 8 P.M.
London Institution, at 4 P.M.—"The Philosophy of Magic." By J. C. Brough. (Holiday Course.)

VACANCIES AND APPOINTMENTS IN CONNECTION WITH PHARMACY.

The Editor will be glad to receive early notice of any vacancies of pharmaceutical offices connected with public institutions, and likewise of appointments that are made,—in order that they may be published regularly in the Journal.

APPOINTMENT.

Mr. F. J. Barrett, Pharmaceutist to the South Staffordshire General Hospital, has received the additional appointment of Chemist and Analyst to the same Institution.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Shall the Pharmaceutical Society cease to be an Educating Body?

Sir,—In response to the editorial invitation that those who hold decided views on this question would communicate them, I make bold to offer a few remarks, though fully sensible of their imperfections. Before so doing, however, I would observe that an important subject as this is deserves the fullest consideration, and it is very desirable that it be freely discussed in all its bearings and positions.

When authorities such as Mr. Mackay and Mr. Schacht speak so plainly and with such confidence, it is time we looked the contingency fairly in the face, and henceforth determine to set our house in order, so that when the time comes we may be prepared to acquiesce in whatever change is deemed most desirable. Thoughtful practical men, men who have the interest of the Society at heart,—and I rejoice to say such are by means few,—must, I think, sooner or later adopt the view expressed by Mr. Schacht, that the duties of teacher and examiner ought not to coexist in the same body. It is a recognized fact that an examination by a Board entirely separate from the teaching faculty is productive of results more valuable and reliable as a test of merit than where the two offices are combined. This principle is accepted by different educational bodies, national and private. In these days the schoolmaster who is wishful to have a thoroughly practical and unbiassed examination for his pupils arranges with such a body as the College of Preceptors, or examiners appointed by one of the universities, to undertake that duty. Governmental, diocesan and some denominational schools—in fact, the majority of educational bodies—are periodically examined by their different inspectors. The Pharmaceutical Society is an exception to this rule. With the one hand it educates, with the other examines those it has educated. However, since 1868, its position and duties are clearly defined. Before that date it was a voluntary body, doing a voluntary work; now it has compulsory powers, and is bound to execute certain duties in return for its privileges, the head and front of these duties being examination, but by no means education. Personally, as an old student of the Society, I shall be sorry to see it deprived of those educational powers it has used through good and evil report for so many years with such undeniable success; but if the majority decide that the separation of functions is beneficial, individual feeling will give way.

Supposing it to be generally admitted that the severance is needed, where are we to look to for the educational part to be carried out? I answer, turn over the pages of the Pharmaceutical Journal,—say during the latter part of the decade of 1850,—and note the scanty number of provincial chemists' associations, whose titles and doings there appear. Afterwards turn to the Journal of the present time, and contrast the large number of associations that are now in healthy, vigorous existence, and already providing a useful technical education. In my opinion, it is to these associations that we must ultimately look for the supply of trained pharmacists; and it seems to me that they will eventually occupy the same position in regard to pharmacy that the different medical schools do to that profession. Suppose we take it for granted that the local schools fulfil the duty of preparing students for examination, it should then be arranged that these schools be the only recognized source of pharmaceutical education after a regular apprenticeship, and that without certificates of attendance on a certain number of classes and lectures at one of them, no student should be eligible for examination,—a similar proceeding to that adopted by most of the medical examining bodies of the present day. The fees received would, I have little doubt, in a short time be sufficient to defray all expenses, and until then the parent Society might reasonably be asked to assist by grants of money and material; or it might adopt the capitation system, and pay over to the school whence the successful candidate proceeded a certain sum of money, according to the excellence of the examination passed.

Already in some of our larger towns do these associations exist, only wanting time and circumstances to develope them into centres of high-class pharmaceutical education.

The examinations then would take place at Bloomsbury Square as usual; in fact, the present arrangements for the conduct of that duty would amply suffice. I think that by a plan something after this fashion we should not find the transition either violent or objectionable, especially as many students are examined at present who have not prepared themselves at head-quarters. Then we should have the local associations doing their own work of educating, and the Pharmaceutical Society its own work of examining and rewarding.

With regard to the plan advocated by Mr. Schacht, I think the great objection to its adoption would be the single yearly examination. Considerably more than the one opportunity is required. It might frequently happen that a young man would lose a favourable opening for commencing business simply because he had not got his diploma, and might have to wait the greater part of a year before he could obtain it; whereas under the present system he need not wait for more than a few weeks, presuming him to be ready in every other respect. Again, I can imagine that an examination by written papers alone is not so satisfactory to the examiners as that in which the *vivâ voce* takes the leading part. Papers are very well as far as they go, but they cannot convey to the mind of the examiner the same impressions as to the capabilities of the pupil that personal intercourse does. These reasons incline me to think that a yearly examination would not meet the necessities of the situation.

The plan thus imperfectly sketched out I am sanguine enough to think will bring about the same results, but in a rather different way, as that suggested by Mr. Schacht. I now leave the matter to the consideration of the readers of this Journal, and hope it may meet with that attention so vital a question demands.

Liverpool, Dec. 6th, 1871. T. H. Hustwick.

Dispensing Difficulties.

Sir,—When my unfortunate paper was written I had not the least expectation of seeing it in print, and quite as little that it would have called forth such a display of virtuous indignation, or I should perhaps not have expressed my ideas in quite such plain terms. I do not, however, yet see that the part so much objected to deserves all the hard words that have been said about it, or that its "whole tendency" is to "lead apprentices or assistants to think they are doing but right if they go a little further, and omit or substitute by others the ingredients of any prescription entrusted to them."

I cannot accept T. B.'s dictum "that if the extracts are evaporated until of suitable consistence for forming pills," there would be no difficulty; for we could scarcely name a single extract which if made the proper consistence for pills would keep in that condition for any length of time; most of them either speedily dry up and become too hard, or attract moisture and become too soft; and in this fact lies the whole difficulty. I dare almost go so far as to ask T. B. if he ever saw any (workable) extract he could form into pills that would *keep their shape*, or that would not go soft without the addition of something to prevent it? and really, the difference in strength between pulv. hyos. and ext. hyos. is so slight as to be hardly worth naming, and I suggested its use in order that as little alteration as possible might be made in the strength of the medicine; moreover, it is a question whether more injury may not be done to the extract in drying it on a slab over the gas as F. W. S. suggests, than would compensate for the difference.

With regard to essential oils, everybody knows that if we put more than a certain proportion into a pill-mass it works out in the manipulation unless some "*dodge*" is practised, and I cannot perceive that it makes very much difference (except as a salve for the conscience) whether the excess is worked out on the fingers and pill-machine, or left out in the first instance, whilst the latter method certainly makes the most satisfactory pill; and with respect to the iron and gentian pills, I would say that I have tried p. ferri sulph., and do not like it, whilst by using a little p. gentian instead of extract, I am able to get in a larger quantity of the oil of cinnamon than I otherwise could do.

I do not know what my critics may think allowable in *their own practice*, but it does seem to me that the addition of 24 gr. magn. calc. to 2 oz. pills, though they be "of convenient size, well made and of good consistence," is hardly consistent with the use of the ugly words to which I have been so freely treated; it appears rather to show that the gentlemen who have been so ready to condemn me are quite ready to adopt any pet schemes of their own, whether in accordance with the intentions of the prescriber or not. I would suggest that in future, when disposed to accuse other people of improper practices, they should be quite sure their own practice is pure; whilst to Mr. Clark I would say that his "presumption that the Manchester chemists have but lax notions of the duties of their calling" strongly suggests one of Æsop's fables which tells how a sick and aged lion was treated by certain other quadrupeds,—only that the Manchester chemists are not yet quite in the condition of the poor old lion.

F. W. S. has mistaken my question in reference to the second prescription named in my letter of the 20th ult. I did not refer to the manipulation at all, but to the directions of the prescriber; the weight of the ingredients was 9 grs., and the directions were "FINGE IN PILULAM. Sumat duas h. s.," and I wished to know what T. B. would have done in that case, the physician not being accessible.

Referring to your article of the 25th ult., where you lay it down as being "clearly and positively the duty of the dispenser to communicate with the prescriber in all cases of doubt or difficulty," no doubt it is so in theory, but hardly possible in practice. There are cases where it is easy enough to do so, as for instance where the prescriber lives near the dispenser, or the hours are known when he may be seen; but suppose the case of a physician residing in another town, or whose name I do not know or for any other reason cannot get access to, and I receive a prescription which contains a palpable error, but I can plainly see what is intended,—am I to decline to dispense it until the prescriber can be communicated with? Should I not rather use my own common sense, dispense the medicine as it was meant to be, and let the patient have it at once, which might be of consequence, and so save all parties from the annoyance a contrary course would have produced?

I do not by any means suppose it the "whole duty" of the dispenser to guess at what he cannot read, to remedy real or imaginary errors, or to reduce a dangerous dose; on the contrary, I believe it to be our duty in all such cases to consult the prescriber where it is possible to do so, but at the same time I do not quite see why the study of chemistry, materia medica, botany, pharmacy, etc. should be so much insisted on if we are not to use the knowledge we possess when occasion requires it.

Cheetham Hill, Dec. 5th, 1871. W. WILKINSON.

THE BRITISH PHARMACOPŒIA.

Sir,—The members of the Pharmaceutical Society, and British pharmacists generally, may fairly congratulate themselves on the paper, by the learned professor of chemistry and pharmacy, read at the last monthly meeting night.

My present purpose is not to advocate the adoption of the metric system; it will come in time, under what names soever the subdivisions might be known in England. But I submit that we should have no objection to its use in pharmacy (including in that term pharmaceutical chemistry) from the public. We should, I think, have only to meet the medical profession and the older members of our own profession. And I would submit to these that the adjustment of the Pharmacopœia would be far more easy than at first sight appears. Hence the association with a given proportion of the active ingredients in a compound need not be rudely disturbed. The change of the unit would not be so very complex a process.

What is the foundation for the quantity implied by "grain" and "minim"? These are the units for both weight and volume. The unit of the metric system was true and easily found while yet a stone of the pyramids was not laid, and it must last to the end of time.

Hence, in multiplying and dividing by 10, I hope we are smoothing somewhat the devious path for students, both medical and pharmaceutical. At present, no anxiety as to manufacturing and philosophical chemistry need have place.

We surely should hardly declare ourselves against so philosophical and easy a change. Our German brethren, left (as I have been assured by a Prussian pharmacist) no less than our own body, in past years, to their own opportunities of acquiring a knowledge of their profession, would hardly award us much credit for our want of "pluck" to grapple with a thing like this.

I have said here nothing as to its adaptability at present to the daily requirements of the community.

W. H. L.

IMPROVED TINCTURE PRESS.

Sir,—I thought it unnecessary to reply to a letter signed "An Old Engineer," but several friends urged me to do so, as it assumes my ignorance of the pressure being greater on a small than on a large cylinder; or, in other words, that a total pressure on a certain superficial area would give the obvious result of so much per square inch! The fact is that only the total pressure has been taken into consideration in the course of this discussion. "An Old Engineer" is evidently prejudiced against my press; yet he confirms my opinion of its originality, simplicity and economy, and, not finding anything to say against its principle and construction, condemns the materials and workmanship as unequal to the power of the implement, in which opinion I cordially agree.

However, it was not to reply to this that I once more trespass on the valuable pages of your journal; but, finding myself involved in a rather serious private correspondence on the subject, it will save much unnecessary trouble if allowed to inform your readers that I am not a manufacturer of, or dealer in tincture presses, but will be pleased to continue to give any information that may be required.

Fulham, S.W., December 11th, 1871. C. A. STAPLES.

THE PRELIMINARY EXAMINATION.

Sir,—The communication from "Veritas" in last week's Journal gives me possession of facts which I would gladly have known before. He informs me that *N. B.*'s master (who, I am glad to see, shares similar opinions with myself respecting him) was unaware of that gentleman's kind attempt to sound his master's trumpet in conjunction with his own.

Now, although I greatly regret giving offence to any one, and willingly retract the objectionable sentence, seeing that it causes "so much pain and annoyance," I may perhaps be allowed to assert, without fear of bringing any further reprovals upon myself, that my remark was a most natural conclusion to draw, when such words were inserted as "now with Mr. J. M. W., Pharmaceutist, Oakham," previous to the glowing account of the examination, for, as a rule, a small amount of credit is reflected on a master when one of those under his charge shows a proficiency in any examination.

In regard to the quotation from Byron to which "Veritas" so kindly treats me, I beg to remind him that even if "critics all are ready made," they have no less power for that reason, —a power which, if rightly used, works infinite good. Could Byron have seen the late controversy on his own character he would, perhaps, have given "Veritas" a few still more sarcastic lines to quote.

In conclusion, let me thank "Veritas" for giving me the opportunity of showing how fair in criticism I wish to be.

December 12th, 1871. W. H. J.

[*⁎* We think that sufficient space has been given to this subject, and the correspondence must now cease.—ED. PHARM. JOURN.]

J. L. W.—You may obtain what you require from any manufacturer of chemical apparatus.

T. A.—Mohr and Redwood's 'Practical Pharmacy.'

W. Sandall.—Fresenius's 'Quantitative Analysis' is a good work on the subject. Quantitative analysis is not an easy operation, and there is no easy book for teaching it. To perform it properly, the operator requires to have a thorough knowledge of chemistry.

"Veritas."—(1.) The Preliminary Examination can only be passed, either in the country or in London, on the days specified in the official notice. See first page of wrapper. (2.) The last edition was published in 1851.

W. D. Williams.—You will find answers to your question in PHARM. JOURN. 3rd ser. vol. i. pp. 377, 397.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. J. J. Nicholson, Mr. J. Hallawell, Mr. R. Bannister, Mr. J. C. Brough, Mr. Chandler, Mr. E. Rimmel, Mr. J. Bradshaw, Mr. T. Appleton. Mr. Stokes, Mr. W. Hills, Mr. W. J. Smith, Mr. A. W. Bennett, "A Commercial Traveller."

"A Yarmouth Member" and "A Country Chemist" have not complied with the rule respecting anonymous communications.

THE EDUCATION OF PHARMACISTS.

BY ONE OF THE FRATERNITY.

The Board of Examiners has just presented to the Council a report, relating to the Preliminary Examination, that reveals a very deplorable state of affairs. We learn from it that an average exceeding 35 per cent. of the youths who presented themselves at four examinations held by the Board failed to exhibit evidence of having received any education whatever. Those who have been curious enough to look over the questions which have been published, will have seen what a very slender stock of erudition will enable a youth to get his certificate. In fact, so slight is the acquaintance with each subject which is expected, that one might be inclined to fall out seriously with the Board upon the matter, were it not for the fact that there still remains a residuum of that class, for whom there is so much clamour for sympathy, on the ground that they had already entered upon the business at the time of the passing of the Pharmacy Act.

It is inconceivable that there should be any doubt about the advisability of a preliminary examination. Those who have the best possible opportunity of judging, namely teachers and examiners, know full well that all the difficulties which arise in subsequent examinations spring from imperfect elementary school training. More than this, masters also must be blind indeed if they do not see every day that their best assistants are those who possess, not merely a superficial acquaintance with the details of their business, but a good general education,—who can write a good hand, cast accounts and keep the books neatly, dispense smartly and intelligently, and show to their customers a ready knowledge of whatever questions may be proposed to them.

Take the subject of Latin, for an instance. A prescription comes in for pills to be taken "hâc et crastinâ nocte." The assistant is alone, and the result of his feeble knowledge of Latin is that the patient is told to "take these to-morrow night;" so either missing one dose of the two that he ought to have, or getting twice as much as he should do to-morrow. This is an instance of what has actually occurred, and the same kind of thing happens day after day. To say no more about the necessity of a little classical knowledge to all pharmacists, because it is self-evident, it is impossible to refrain from pitying the student who begins to work at botany, or any other branch of natural history, without some slight acquaintance with both Latin and Greek.

English grammar and composition are down in the synopsis issued by the Examiners. Justly so, and, in the opinion of many people, they ought to take first rank. But while confessing to a strong leaning in the same direction, it must be admitted that every candidate ought to be required to show a certain familiarity with standard English literature, for with all due respect to Messrs. Lindley Murray and Co., it is only from that source that a knowledge of English grammar and composition can be usefully derived. It is not to be expected that boys of 16 to 20 should be able to handle the pen of Macaulay, or display the elegance of Charles Lamb, but they ought all to be able to write a decent letter in a decent hand, and describe in an intelligible and connected style what they may have seen, or what they think about a given subject. It can surely be no advantage to a man who wishes to inspire his customers with a respect for what he conceives to be his superior scientific attainments, if he communicates with them in vulgar or ungrammatical language, with a carelessness of aspirates or neglect of common syntax rules. He is more likely to get a name the reverse of that to which he aspires.

Those possessing some considerable experience as teachers, would say that for students of chemistry there is no more desirable accomplishment than a modicum of mathematics, nor one that is more commonly wanting. In this respect the writer's experience differs from that of the Examiners, whose report asserts that arithmetic is nearly always well done at the examinations. It would be a shame indeed if it were not. The greater part of the questions set are so trivial, that a sharp child of ten years would do the whole easily. But the complaint to be made is that while three-fourths of existing students of pharmacy cannot manage simple rule of three, about the same proportion have no acquaintance with such things as decimal points, To expect such pupil to have any idea of the fundamental nature of an equation, or ever to have dreamt of the first rudiments of algebra, would be indeed an enormity. And yet at the threshold of the study of chemistry rises up a big stumbling-block, which nearly all beginners blunder and hurt themselves over, simply because they never heard of such a thing as a symbol before, and have to grapple with an idea to them absolutely new. It is really almost too bad to put material of this kind into the hands of a teacher and say, "Make a chemist of this boy." The teacher can hardly be expected to get up much enthusiasm when he has to halt every now and then to give a lesson in arithmetic.

Then comes the question, what is the cause of all this, and how can it be remedied?

The answer is plain. The parents and guardians of these unlucky youngsters, being in most cases themselves ignorant people, have never seen the use of having their boys taught anything. A venerable individual who had made a considerable fortune as a currier, used to ask what was the good of such rubbish as French and drawing, because he had got on very well without them? That sort of thing was possible; times are changed since, and "the three *Rs*" must be laid hold of if a man wants to live in this world. To have learnt thoroughly the "ingenuas artes" not only "emollit mores," but it requires time. Those in authority who suggest such things as "polishing up," and advise a month or two of reading Latin grammar, are to a certain extent responsible for the continuance of the wretched state of things to which we have drawn attention. If a man's education has been neglected, it is *impossible* that he can recover the lost ground in a few months, it can be done only by patient application for a year or two.

But it may be asked, What is all this about? It is simply this—there is a great question staring the pharmacists of this country (and, indeed, others) in the face. What kind of position is the pharmaceutical practitioner to take in the up-springing generation? Is he to remain on a level socially with his next-door neighbour the oilman and the greengrocer; or is he to be an educated and intelligent man, not merely respectable and respected as a trader, but second only to the physician himself in professional dignity or social and scientific importance? This question remains for solution by the members of the pharmaceutical body. They have the world full of young men before them, they can choose, as they please, either the idle and the dull or the active and the intelligent. But whichever they elect into their ranks, the recruit, be it always understood, has no rights when he enters beyond those of every citizen. The way then is clear: if it is really the ambition of chemists and druggists to improve the position of their body, they must do what they can to make the body deserving and capable of advancement. And this can be done only in one way. They must see that they do not assist in any way towards admitting fresh incapables into the trade which they would fain see elevated in status, or even modified into a profession. It is no exaggeration to affirm, that every man accepting a youth as pupil or apprentice who does not exhibit the capacity and activity necessary to enable him to master every detail of his calling, is doing an injustice to the boy, an injury to the community, and is deliberately balking those efforts which have been, with increasing success, carried on for the last thirty years. Nothing now stands in the way of the pharmacist but himself. It is earnestly to be hoped that better things will in time arise. But, meanwhile, there is the Preliminary examination to be faced. Let every chemist and druggist throughout the country make it a rule to take no apprentice who has not passed that test satisfactorily, and then a great step will have been gained. Further doings can be spoken of afterwards.

Youngsters themselves may be warned that the examination is not the end; they should not regard it as such. They should not go near the examiners till they are at home in every subject, for they may depend upon it, that without possessing, and being able to use, the knowledge which the passing of this examination is supposed to guarantee, the mere acquisition of the certificate will only make fools of them.

LIQ. MAGNESIÆ BISULPHITIS, A REMEDY FOR CARDIALGIA (HEARTBURN).

BY GEORGE ARCHBOLD, D.SC.

Some time ago a physician asked me the question, "Do the bisulphites prevent the butyric acid fermentation?" In order to give him an accurate answer, I promised to try two experiments. This I did. First, I proceeded to make butyric acid by fermentation of a mixture of chalk, cheese, and honey and water, and allowed the mixture to stand for four days. Secondly, in another vessel I proceeded in the same manner, using the same ingredients, with an addition of bisulphite of lime; set it aside for four days with the first, keeping them at a temperature of 80° F.; after which I subjected each to distillation with a little H Cl.* From the *first* I recovered a considerable amount of butyric acid, but from the second (containing bisulphite) I did not recover a trace. This at once proves that the bisulphites do prevent butyric acid fermentation. Now the object in ascertaining the fact was that a suitable remedy for heartburn might be discovered, as, according to Dr. Leared, this common complaint is due to the presence of butyric acid in the stomach. "On considering the taste," says that gentleman, "experienced, as well as the conditions under which heartburn comes on, it seemed to me that the cause of it was the presence of butyric acid;" and from many experiments performed by that gentleman on himself and others by means of the pure acid, symptoms were produced in every respect similar to the complaint itself, so that there can be little doubt but that his theory is a correct one. The very fact that alkalies give relief prove its cause to be from an acid. When the stomach is overtaxed, and in certain weak conditions of digestion, fermentation takes place; butyric acid is set free from the food, *i. e.* it is formed out of its own elements, if the food be of a starchy nature; and, according to Leared 'On Imperfect Digestion,' page 249, "the acid, by being in excess, but not pure (or it would be soluble), rises to the surface of the contents of the stomach, when it combines with melted fats (for which it appears to have a strong affinity); the acrid mixture, on being presented to the cardiac orifice by the motions of the stomach, is instinctively rejected into the œsophagus, and, by the reversal of its proper movement, transmitted to the mouth, accompanied by the sensations of heartburn." Now, as bisulphites have the power of preventing this fermentation, they are well worthy the attention of the profession, but the great drawback is that the chief bisulphite manufactures are those of lime, soda and potash, these being objectionable, as they tend to injure the coats of the stomach. To remedy this failing, the thought at once suggested itself to me that a bisulphite of magnesia might be prepared; and magnesia being free from these objections, it may prove a valuable remedy, and is worth notice. I have not seen or heard anything of the preparation previous to my making it. I therefore give a brief outline of the process I adopt, and hope to enter more fully into the subject at a future time. I first treat magnesia carbonate with B. P. sulphurous acid, which, on evaporation, yields magnesia sulphite, $Mg\,S\,O_3$, which is not very soluble in distilled water. I then mix the sulphite of magnesia thus formed with distilled water, in the proportion of 16 grs. to ℥j, and pass into it sulphurous anhydride until a clear solution is obtained. The result is a solution of magnesia bisulphite.

The dose may be one tablespoonful, containing about nine grains of the salt; its action is a mild aperient antiseptic, preventing butyric fermentation in the stomach, etc. I have tried it myself and on two other gentlemen, and, as far as I can judge, it has the desired effect.

* For the first two days lactic acid is formed, which combines with the lime, but at the expiration of four days, the lactate of lime is replaced by butyrate of lime, which on being distilled with dilute hydrochloric acid, and the distillate treated with calcium chloride, is dried into two strata, the upper being butyric acid.

THE USES OF THE GENUS CYPERUS.

BY JOHN R. JACKSON, A.L.S.

Curator of the Museums, Kew.

Few Natural Orders are less important in a medicinal or economic point of view than the *Cyperaceæ;* amongst its British representatives there is scarcely a plant of any real value. Botanically, the genus *Carex* is the most important, no less than fifty-eight species being recorded as British. Of *Cyperus* itself two species only occur with us,—*C. longus*, L., and *C. fuscus*, L., but both of these are very rare; the rootstocks of the former, which are aromatic, were, at one time, used as a tonic and stomachic. The tubers of several species are used both medicinally and for food in India; those of *C. bulbosus*, Vahl—a plant growing in sandy situations near the sea on the Coromandel coast—are eaten either roasted or boiled, the skins being rubbed off between a cloth; they are said to taste like potatoes. Sometimes they are dried in the sun and ground into flour, from which bread and other articles of food are made. Stewed, or used in curries, they are also reputed to be very good.

Cyperus rotundus, L. (*C. hexastachys*, Rottl.), is another Indian species, common in moist localities throughout the empire; the tubers of which are about the size of a pigeon's egg, and are sold in the bazaars; they are white, friable and spongy, having a sweet, aromatic odour, and a bitter, balsamic and resinous taste. They are used by perfumers on account of their fragrance, and by native practitioners as a tonic and stimulant, and in cases of cholera. In a fresh state they are employed for making an infusion, which is given as a demulcent in fevers, and in cases of dysentery and diarrhœa.

An account is given in the *Calcutta Med. Phys. Transactions* of two cases of cholera alleged to be successfully treated with them.

The entire plant is much relished by cattle, and hogs are very fond of the roots.

The roots of *C. odoratus*, L., have a warm and strongly aromatic flavour, and are used in native practice as a stomachic; those of *C. pertenuis*, Roxb., are likewise aromatic, and are used when dried and powdered by Indian ladies for cleaning and perfuming the hair; they are also regarded as diaphoretic and diuretic. *Cyperus repens*, Ell., is cultivated about Charleston, and the sweet roots are largely sold as an edible under the name of grass nut. *C. hydra*, Mx., has become a great pest in some parts of the southern States of America; the plant is in no way useful, but is very difficult to eradicate.

C. esculentus, L., is perhaps the best known of all the species; the tubers, which are mealy, have a very aromatic and agreeable flavour, and are used as food in the South of Europe; they are called by the French, "*Amande de terre*." In Madrid, during the hot weather, they are a regular article of trade, and are sold under the name of *Chufas*, for making a cooling drink; for this purpose they are soaked for two days in water, after which they are powdered, and the liquid strained off and frozen, the result being a most pleasant and refreshing drink.

OIL OF WINTERGREEN.

BY DR. J. E. DE VRY.

In reading the note on "Oil of *Andromeda Leschenaultii*" on page 285 of this Journal, I supposed it would be of some interest to publish some experiments on a similar subject which I made in 1859 when I was in Java. The presence of large numbers of *Gaultheria punctata* and *Gaultheria leucocarpa* on the tops of many volcanoes of that island having attracted my attention, I collected the leaves of both of them on the extinct volcano Patoea, with the view of ascertaining the amount of essential oil to be extracted from them by distillation.

65 pounds of fresh leaves from *G. leucocarpa* yielded 40 grams of oil, amounting to about 0·012 per cent.

59 pounds of fresh leaves from *G. punctata* yielded 340 grams of oil, amounting to about 1·15 per cent.

Both these oils are almost identical with the American wintergreen oil, as I found them to consist chiefly of methyl-salicylic acid. I brought them home, and presented them to the chemical collection of the Polytechnic School at Delft.

If wintergreen oil is really in great request by certain manufacturers, I suppose it would be made with profit in Java from *G. punctata*.

As Zwenger found quinic acid in the leaves of *Vaccinium Myrtillus*, I supposed that both the species of *Gaultheria* mentioned as belonging to the same natural family, might contain the same acid. Therefore, after distilling the oils, I examined the residue in the still, and found the expected quinic acid, as was proved by its deviation of the plane of polarization to the left and by the production of hydrochinon, if treated with manganese and sulphuric acid.

VESICATING INSECTS.

BY M. C. COOKE, M.A.

(*Continued from page* 424.)

North American Cantharides.

Black Blister-Fly, *Lytta atrata*, Oliv.; entirely black and immaculate.—Oliv. Ent. t. 2. f. 19; Durand, Journ. Phil. Col. Pharm. ii. p. 274. f. 7; Wood and Bache, Disp. U.S. (1867) p. 206; Harris, Injurious Insects (1862) p. 139. f. 64. *Lytta atrata*, Fabr. Sys. p. 260; Brandt and Ratzb. ii. t. xviii. f. 9. *Cantharis pennsylvanica*, De Geer, Mem. v. t. 13. f. 1. *Epicauta pennsylvanica*, Leconte, Cat. Col. U.S.

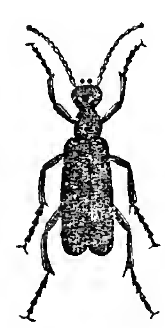

Fig. 9.—*Lytta atrata.*

Found in North America, Carolina and Pennsylvania.

The black *Cantharis* is smaller than the other indigenous species, but resembles *C. marginata* in figure. Its length is only four or five lines. It is distinguished by its size and its uniform black colour. It frequents more especially the different species of *Aster* and *Solidago*, though it is found also on *Prunella vulgaris*, *Ambrosia trifida*, and some other plants. Mr. Durand met with considerable numbers of this insect near Philadelphia in the month of September; and they continued to appear till the middle of October. They are common in the Northern and Middle States, but are not confined exclusively to this country, being found also in Barbary. Drs. Oswood and Harris, of New England, satisfactorily ascertained their vesicating powers. They are probably identical with the insect noticed as vesicatory by Professor Woodhouse, under the name of *Meloe niger*.

This species is thus noticed by Harris in his 'Insects Injurious to Vegetation.'

"About the middle of August and during the rest of this and the following month, a jet-black *Cantharis* may be seen on potato-vines, and also on the blossoms and leaves of various kinds of golden-rod (*Solidago altissima*), which seems to be its favourite food. In some places it is as plentiful in potato fields as the striped and margined *Cantharis*, and by its serious ravages has often excited attention. These three kinds, in fact, are often confounded under the common name of potato flies; and it is still more remarkable that they are collected for medical use, and are sold in our shops by the name of *C. vittata*, without a suspicion of their being distinct from each other. The black *Cantharis* or *C. atrata* is totally black, without bands or spots, and measures from $\frac{4}{10}$ to $\frac{1}{2}$ inch in length. I have repeatedly taken these insects in considerable quantities, by brushing or shaking them from the potato vines into a broad tin pan, from which they were emptied into a covered pail containing a little water, which, by wetting their wings, prevented their flying out when the pail was uncovered. The same method may be employed for taking the other kinds of cantharides, when they become troublesome and destructive from their numbers; or they may be caught by gently sweeping the plants they frequent with a deep muslin bag-net. They should be killed by throwing them into scalding water for one or two minutes, after which they may be spread out on sheets of paper to dry, and may be made profitable by selling them to the apothecaries for medical use."

The black blister-fly is one of the species recognized in the United States Dispensatory, and is commonly employed in the Northern States.

Nuttall's Blister-Fly, *Lytta Nuttallii*, Say; bright green, varied with golden; elytra golden-purple; feet black; thighs blue; trochanters armed with a spine.—*L. Nuttallii*, Journ. Acad. Nat. Sc. iii. p. 300; Say's 'Entomology,' i. p. 5. t. iii. f. i.; Wood and Bache, Disp. U. S. p. 207.

Body glabrous. Head deep greenish, varied with golden. Front punctured, subimpressed, and with a small rufous spot. Antennæ robust, surpassing the base of the thorax, black, opaque. Joints turbinate, approaching to moniliform; the margin of the tip rounded; second joint two-thirds of the length of the third; terminal joints largest near the middle, and rapidly attenuated to an acute tip. Eyes oblong-oval, emarginate. Palpi black. Clypeus and labrum obscure. Thorax golden-green, polished with unequal, minute, sparse punctures; a longitudinal, dorsal, impressed line, and a transverse basal one. Base bluish; anterior angles prominent. Scutel blue, obtuse behind. Elytra red or golden-purple, somewhat rugose; two indistinct elevated lines on the disk and a submarginal one, beneath green, polished. Feet black. Thighs beneath blue or purplish. Trochanters armed with a conic spine near the inner base, obsolete or wanting in the female.

A noble species which, in magnitude and splendour, is said to surpass the famed *vesicatoria*. It seems to have the habit of *Lytta*, combined with a form of antennæ allied to that of *Mylabris*. Say writes thus concerning its discovery:—"In company with Major Long, I observed it, for the first time, near the base of the Rocky Mountains. A very numerous flock had there taken possession of the few diminutive bushes that occurred within the space of a hundred yards, every spray of which was burdened with their numbers. After passing this limited district, not an individual was seen during the remainder of our journey. On the recent expedition of the same officer to the river of St. Peter, I obtained but a single specimen, which was found one evening at an encampment in the N. W. Territory."

According to the American Dispensatory this species bids fair, at some future period, to be an object of importance in the Western States. Colonel Long ascertained its vesicating powers, and in one place is said to have found it so numerous and troublesome as to be swept away by bushels in order that a place might be found for encamping.

(*To be continued.*)

OBSERVATIONS IN PRACTICAL PHARMACY.*

BY CHARLES SYMES, PH.D.

Evening meetings are usually the most unsatisfactory part of societies; all feel this to be the case, and yet all do not equally endeavour to provide a remedy which we know is to a great extent in our own hands. Mr. Vizer, in a letter to the Pharmaceutical Journal a few weeks since, suggested that on these occasions we should soar higher than the objects of every-day life, and invite some of the great men of science to enliven our latent energies, and so increase the attendance; this idea is not altogether a bad one, but if we depended on such stimulants, it would soon be evident that the object for which we meet would, in a great measure, have become frustrated, the resultant good (as affecting the whole profession) would not be equivalent to our numerical strength. One of my earliest associations with the Pharmaceutical Society was attendance at an evening meeting at Bloomsbury Square, when Dr. Redwood read a paper on "Citrate of Magnesia" (some twelve or thirteen years since). I never saw a meeting better attended; the subject was commonplace enough, but one of practical importance to the pharmaceutist. Again, when two of us meet together and talk over the many little difficulties which daily present themselves, the means by which we render simple processes more simple, difficult processes less so, we return to our duties with renewed energy, a better feeling and more loyalty towards the cause of pharmacy. Now it is my opinion that our evening meetings should, to a large extent, be a development of this communion, and the result a similar profitable gratification intensified.

This then must be my apology for bringing before you the following practical subjects this evening.

Soap Liniment is a preparation which at one time received much attention, but which remains very much as it was, an unsatisfactory one. Messrs. Southall and Co. were the first to call my attention to a soap which they had prepared, which was entirely soluble in the proportions of spirit and water ordered by the B. P. (18 and 2), and which remained bright down to a temperature of 32°; the same soap, however, kept for two or three months, did not fulfil these conditions. A little reflection made the cause evident. In its fresh state, this in common with all other soaps contains a large proportion of water, so that practically we in using it are adding rather more water and rather less soap, and so make the Pharmacopœia preparation what it really should be; and in using this soap when dry and hard, it is necessary for uniformity and for getting a satisfactory preparation, to use rather less soap and rather more water. Mr. Wood introduced to our notice an almond oil soap, which I have prepared, and found to answer admirably, keeping bright at any temperature to which I have exposed it; but I have no experience of its use when old and hard. A liniment prepared with Pharmacopœia soft soap (using the proper proportions of spirit and water) also keeps well, and appears to possess as much therapeutic value as that prepared from hard soaps, still we are scarcely justified in using it when the Pharmacopœia directs the latter.

Syrup of Phosphate of Iron.—The length of time which this preparation might be kept without change is said to be entirely dependent on the acid from which it is prepared being freshly diluted or otherwise. I have found a slight modification of a United States formula answer well for the preparation of the syrupy or dilute acid. Dissolve 1000 grains of glacial phosphoric acid (free from phosphate of ammonia) in 6 ounces of distilled water, add 1 drachm nitric acid, and boil down, in a porcelain dish, to the consistence of a syrup, or until all the nitric acid disappears. When nearly cold, it might be diluted if required for immediate use, so as to produce

* Read at a Meeting of the Liverpool Chemists' Association, Nov. 23, 1871.

22 fluid ounces, which will correspond with the acid. phosph. dil. of the B. P.

Syrup of the Phosphates (Parrish's Chemical Food).—This preparation, as sent out by the original maker, varies considerably in appearance, sometimes being of a bright crimson, sometimes of a dark mahogany colour; but he having published his formula, cannot, of course, retain it as private property, and the preparation is now largely made, both by wholesale and retail houses, and more uniformity appears to exist in consequence.

The operation is comparatively simple, and yet occasional difficulties present themselves, either in getting the whole of the phosphates dissolved without an excess of acid, in getting the whole of the sugar dissolved without its settling as a gummy, tenacious and partly insoluble mass, or in preventing a deposit of some of the phosphates when completed. (Parrish's own make frequently contains a deposit.) I manipulate as follows:—First dissolve the glacial acid in a very small quantity of distilled water, precipitate the phosphates of iron and lime, taking care with the latter not to add ammonia in excess, and slightly acidulating the water used in washing with hydrochloric acid; with a small quantity of the concentrated solution of phosphoric acid neutralize the potash and soda, and in the remainder dissolve the above precipitates—mix and measure; the quantity of water which it would be necessary to add to make up the required bulk of fluid, will be found sufficient to form separately, with the sugar, a thick syrup; slightly acidulate this with a few drops of hydrochloric acid, add the cochineal, and into it filter the solution of the phosphates, add the orange-flower water, strain through flannel, and the whole is completed. This syrup has a beautiful crimson colour, is always uniform in appearance and taste, keeps well, and is essentially in every particular syr. ferri phosph. co. (Parrish's)—or Parrish's Chemical Food.

CONTRIBUTIONS TO THE HISTORY OF THE OPIUM ALKALOIDS.*

BY C. R. A. WRIGHT, D.SC.

Lecturer on Chemistry in St. Mary's Hospital Medical School.

PART III.

(*Continued from page* 486.)

2. *Action of Water on the foregoing Compounds.*

When either of the two first compounds just described is dissolved in a large bulk of hot water, and the solution allowed to cool, solid white flakes are obtained containing more C and H, and less I, than the original substance. By repeating this treatment several times successively, the same ultimate compound appears to be produced in each case, being apparently formed by the reactions—

$$C_{68}H_{86}I_2N_4O_{12}, 4HI = 2HI + 2H_2O + C_{68}H_{80}N_4O_{10}, 4HI.$$

$$C_{68}H_{82}I_2N_4O_{10}, 4HI = 2HI + C_{69}H_{80}N_4O_{10}, 4HI.$$

The removal of the last traces of basic HI is very difficult; it may be accelerated by adding a few drops of sodium carbonate to the boiling solution and filtering hot from the small amount of precipitated base; the product is apt, however, to be more strongly yellow-coloured when obtained in this way than when got by treatment with water alone.

Specimen A. Got from compound $C_{68}H_{82}I_2N_4O_{10}, 4HI$ by water and a little sodium carbonate:—
0·366 grm. gave 0·672 CO_2 and 0·177 H_2O.
0·406 grm. gave 0·227 AgI.

Specimen B. From same compound by water alone:—
0·369 grm. gave 0·674 CO_2 and 0·174 H_2O.
0·4555 grm. gave 0·2675 AgI.

Specimen C. From compound $C_{68}H_{86}I_2N_4O_{12}, 4HI$ by water alone:—
0·4265 grm. gave 0·762 CO_2 and 0·220 H_2O.
0·3845 grm. gave 0·2275 AgI.

	Calculated.		Found. A.	B.	C.	Mean.
C_{68}	816	50·25	50·08	49·81	48·73	49·54
H_{84}	84	5·17	5·36	5·24	5·73	5·41
N_4	56	3·45	—	—	—	—
O_{10}	160	9·85	—	—	—	—
I_4	508	31·28	30·21	31·74	31·98	31·31
$C_{68}H_{80}N_4O_{10}, 4HI.$	1624	100·00				

Specimen A, dissolved in hot water and precipitated by sodium carbonate, yielded a yellowish-white substance, rapidly becoming darker, and finally almost black. Dried rapidly at 100°:—

0·370 grm. gave 0·930 CO and 0·235 H_2O.

About 0·5 grm. examined qualitatively for iodine gave only traces of AgI.

	Calculated.		Found.
C_{68}	816	68·46	68·55
H_{80}	80	6·71	7·05
N_4	56	4·70	
O_{15}	240	20·13	
$C_{68}H_{80}N_4O_{10} + O_5$	1192	100·00	

From these numbers it appears that the free base, like bromo- and chloro-tetra-codeia, rapidly absorbs oxygen from the air.

Probably there exists a compound intermediate between the hydriodate just described and the original body—

$$C_{68}H_{82}I_2N_4O_{10}, 4HI;$$

thus one batch of flakes got by two treatments with water of this original substance gave the following numbers after drying at 100°:—

0·3225 grm. gave 0·556 CO_2 and 0·153 H_2O.
0·3205 grm. gave 0·212 AgI.

Another specimen obtained similarly:—
0·4175 grm. gave 0·269 AgI.

	Calculated.		Found.	
C_{68}	816	46·58	47·2	—
H_{85}	85	4·85	5·27	—
I_5	635	36·24	35·75	34·82
N_4	56	3·20		
O_{10}	160	9·13		
$C_{68}H_{81}IN_4O_{10}, 4HI$	1752	100·00		

It is not impossible that this substance is not a definite compound, but only a mixture; nevertheless, a free base of this composition and its hydriodate have been obtained by the action of sodium carbonate on the compound,

$$C_{68}H_{86}I_2N_4O_{12}, 4HI;$$

from whence it appears probable that the body analysed is really a definite compound, formed by the reaction,

$$C_{68}H_{86}I_2N_4O_{10}, 4HI = HI + C_{68}H_{81}IN_4O_{10}, 4HI.$$

Both the final and intermediate products have a very curious structure under the microscope; although they simulate in a high degree the appearance of crystals as they separate from a hot aqueous solution, yet on microscopic examination they are found to consist of strings

* Read before the Royal Society, November 16, 1871.

of coalesced globules not unlike the yeast-plant. In qualitative reactions all the bodies hitherto described are very similar: ferric chloride gives no coloration to the aqueous solution of the hydriodate; silver nitrate is reduced on standing, producing a yellow tint; nitric acid gives an intense yellow; sulphuric acid and potassium dichromate only separate iodine: sodium carbonate throws down a white precipitate scarcely soluble in excess, and soon becoming yellow, salmon-colour, and finally dark brown; ammonia gives a similar precipitate somewhat more soluble in excess, while caustic potash readily dissolves the white precipitate first formed. In many of these reactions this group of codeia derivatives utterly differs from the bodies got by the action of HCl or HBr: most of these latter derivatives give colours with ferric chloride and sulphuric acid and dichromate; all give a blood-red with nitric acid, while the free bases turn more or less *green* by exposure to air.

On similarly treating with boiling water the compound $C_{68}H_{82}I_2N_4O_6, 4HI$ formed by the action of hydriodic acid on codeia at about 130°, a substance similar in characters to that got from the other two compounds is produced; the final product, however, differs somewhat in its physical characters from those just mentioned; instead of coming out from the hot aqueous solution in solid flakes, it appears in very minute solid oil globules which do not readily subside, and give to the liquid a great resemblance to fresh milk; sometimes the globules do not subside for many days.

Dried at 100°, these globules give numbers indicating a compound analogous to that of the non-iodized base just described; it is, however, much more difficult in this instance to remove the last portions of basic HI; moreover, 4 molecules of water appear to be taken up, probably in lieu of the oxygen lost.

Specimen A. Original substance treated three times with large excess of water—

0·3315 grm. gave 0·589 CO_2 and 0·175 H_2O.
0·299 grm. gave 0·178 AgI.

Specimen B. Original with water four times—

0·321 grm. gave 0·585 CO_2 and 0·169 H_2O.
0·411 grm. gave 0·754 CO_2 and 0·218 H_2O.
0·2835 grm. gave 0·165 AgI.

Specimen C. Original with water five times—

0·4095 grm. gave 0·740 CO_2 and 0·219 H_2O.
0·3995 grm. gave 0·237 AgI.

	Calculated.		Found. A.	B.		C.	Mean.
C_{68} . .	816	50·00	48·46	49·71	50·03	49·68	49·47
H_{92} .	92	5·64	5·87	5·85	5·89	5·94	5·89
I_4 . .	508	31·13	32·17	31·45		32·06	31·86
N_4 . .	56	3·43					
O_{10} . .	160	9·80					
	1632	100·00					

$C_{68}H_{88}N_4O_{10}, 4HI$.

Hence this compound is to be formed by the reaction—

$$C_{68}H_{82}I_2N_4O_6, 4HI + 4H_2O = 2HI + C_{68}H_{88}N_4O_{10}, 4HI.$$

Carbonate of soda threw down from Specimen C. a white precipitate, becoming yellow on standing: this precipitate contained a small amount of iodine, showing (as the above numbers indicate) that the transformation of the original substance was not absolutely complete.

The qualitative reactions of this substance are the same as those of the bodies previously described.

(*To be continued.*)

NEUTRAL SULPHATE OF PHYSOSTIGMATIN.

In consequence of the frequent use by practitioners specially devoted to the treatment of diseases of the eye of neutral solutions of physostigmatin or eserin, and the difficulty of obtaining that alkaloid in a state of purity, the author has been led to investigate the subject, and describes a direct process for preparing solutions of neutral sulphate of physostigmatin. One part of hydro-alcoholic extract of Calabar bean is dissolved in four parts, or a sufficiency, of distilled water, and the solution filtered. The small residue which remains in the filter contains none of the alkaloid. One gram of bicarbonate of potash is added to each twenty grams of the extract, and agitated with an excess of ether. The ether becomes distinctly alkaline, and may easily be separated by reversing the bottle, and allowing the aqueous liquor to run away. After standing a short time, so that it may contain no trace of the bicarbonate of potash, the ether, charged with physostigmatin, is poured into another bottle. To this a small quantity of distilled water is added, and then, drop by drop, a titrated solution of sulphuric acid, containing as nearly as possible forty grams of monohydrated sulphuric acid (SO_3HO) to the litre; so that one drop, or 0·05 gram, would correspond to the quantity of physostigmatin necessary to form 0·01 gram of neutral sulphate of physostigmatin. It should be shaken after the addition of each drop, and the point of saturation ascertained by the use of litmus paper.

The aqueous solution is then separated, and the ether, which has parted with the whole of the physostigmatin, is returned to the original and as yet only partially exhausted aqueous solution of extract of Calabar bean. After being agitated and becoming again charged with the alkaloid, it is removed as before, and added to the aqueous solution of neutral sulphate, which, upon the addition of the requisite number of drops of sulphuric acid, takes up all the physostigmatin it contains. This operation, three or four times repeated, will be sufficient to exhaust the solution of the extract, and the same ether will serve throughout.

This solution would suffice for medical purposes, but, to obtain the sulphate in a state of great purity it should be treated in exactly the same way as the original mother liquor. The solution of sulphate of physostigmatin so obtained gives, when evaporated to dryness, elongated prismatic microscopic crystals, but in general the liquors are heated in a water-bath, to evaporate the ether and alcohol they contain.

By adding sufficient water to obtain as many grams as it has been necessary to use drops of sulphuric acid, a solution is obtained containing one centigram of physostigmatin to the gram. One drop of a collyrium containing one gram of this solution to nine grams of distilled water decidedly contracts the pupil, but the quantity generally used is two grams of the solution to eight grams of water.

The author reports that he has obtained very fine crystals of iodide of physostigmatin, by adding tincture of iodine to a solution of sulphate of physostigmatin.—*Journal de Pharmacie et de Chimie.*

PREPARATION OF SULPHURETTED HYDROGEN.

BY JOHN GALLETLY.

In making some experiments on the action of sulphur on paraffin, I have found that a mixture of these substances, either in equal parts or with a larger proportion of sulphur, when heated in a flask not greatly above the melting-point of the sulphur, begins to evolve sulphuretted hydrogen, and continues to give off this gas steadily, while kept moderately heated, for a considerable time.

I have used this process repeatedly, and consider it the most convenient for laboratory use. With a round flask holding about a pound of the materials fitted with a tube bent at right angles about ½-inch bore and 12 to 18 inches long, containing a little loose cotton wool, and having a smaller tube fitted to the end of this for dipping into the liquid through which it is desired to pass the gas, a convenient stream can be obtained lasting several days. The production of the gas can be stopped and renewed at pleasure by withdrawing or applying the heat. An Argand lamp should be employed, or if a Bunsen is used, the top piece should be on the tube for spreading the flame, so as to avoid heating the flask on one spot. Heavy paraffin oil used for lubricating machinery can be substituted for the solid paraffin, and good results are also obtained with commercial stearic acid, but with the latter the tube conveying the gas soon becomes covered with drops of a milky liquid, which is probably water and finely divided sulphur. With paraffin the tubes remain clear and bright, except for a little sulphur sublimate close to the neck of the flask.

I observe that Reinsch recommends a laboratory process for obtaining pure sulphuretted hydrogen by heating in a glass flask equal parts of sulphur and suet. The recommendation does not seem to have been generally followed, but the advantages resulting from the substitution of paraffin for suet may lead to the more usual adoption of this process.—*Chemical News.*

MEDICINAL HERBS AND QUACKERY.*

BY ALEXANDER FORSYTH.

If there be any one sort of gullibility more rampant than another in this city of Manchester, it is that of persons placing implicit reliance upon the quackery of the uneducated herb doctor; and not on him alone, for the engine-tenter in my own neighbourhood fills up his spare hours by salving all kinds of sores, and even goes so far as to lance finger-ends that have been mismanaged before he took them in hand.

"But oh, what peril doth environ
The man that meddles with cold iron;"

for the cures thus effected are not always creditable to the practitioner. Still in the face of the fact of the Manchester Infirmary being one of the best-managed institutions in the kingdom, we constantly hear the old cuckoo cry that such-and-such an herb doctor cured scores of patients after all the leading men of the faculty had pronounced the case to be incurable. Burns laid the lash on most unmercifully when he painted Death and Dr. Hornbook discussing the merits of Buchan's 'Domestic Medicine.' With every new generation of men there arises a new crop of quacks. As, however, I am only cavilling with the herbalist, I would but remark in passing that there are apparently three classes of these unlawful practitioners of the healing art.

The first, by what Cobbett called "mere hardness of mouth," advertises himself as competent to do impossibilities,—for nothing less would do,—and of his 'Materia Medica' the world knows nothing. He addresses himself to moneyed people, and it is for such only that his *olla podrida* is provided. The second lives by the middle class, who consult herbals and doctor themselves and others by rule and order. The third has no literature, and his method of working consists in unwritten notions of old crones who have their "heal-all," and by means of a few herbs, easily obtained at the right time of the year, they confidently assert the cure of almost all complaints, as the old ballad has it,—

"Oh, they say it's sure to do it, and it's sure to do it well.
But the first thing you must swallow is the vegetable pill."

Such parties visiting the poor are to be dreaded, for they give advice gratis, and push their opinions into practice regardless of the fearful consequences of powerful medicines misapplied. To persons struck down with disease, and so unable either to cope with them in argument or keep them at a distance, that which might have been an angel's mission becomes an awful visitation.

But to return to the family herbals. Here before me lies Thornton's Guide to the natures and properties of the various plants used in medicine, etc., the plants drawn from Nature. The English and botanical names are given, the Linnean Class and Orders; the Latin and French languages are freely quoted; and what has been handed down from sire to son unchallenged is still to be seen figuring by way of information. I will just instance the author's remarks on one or two plants, such plants as the late Dr. Lindley said were of no known use to mankind. Many years ago I read in some religious book that persons sleeping under the shade of the chaste-tree became chaste. This chaste-tree should rather be called chaste-bush, for the *Vitex Agnus-castus* grows only to the size of a broom-bush on a common. Now, this good property in the *Vitex* would, to use a medical phrase, evidently be for "outward application only;" say, for a dose, a mere twig, like that of mistleto, might be hung up where its services were required. But our author of the 'Family Herbal' improves upon the doctrine of the Divine, and speaks of the four-seeded berry of the *Vitex* as monks' pepper, giving the Latin for the same, *Piper monachorum*, to confirm the respectability of the name, though Cobbett remarked that when nonsense was translated into French or Latin it was but nonsense still. So the doctor speaks of bachelors taking the *Vitex* berries, indeed, "flying to them;" this would amount to "taking them inwardly." Imagine a school-board in these days ordering a tiny besom made of *Vitex* twigs to be suspended in the class-rooms, and a few pecks of the berries scattered about for the youngsters to nibble at, just as cage birds get groundsel, shepherd's-purse and chickweed! The doctor is seen to the greatest advantage when he comes to treat of the common field orchis, *O. mascula*, where he quotes Sir John Hill's 'Materia Medica' for the following:—"A fellow known to Sir John was once every year brought before the magistrates to answer for his evil deeds, and he always excused himself by saying that orchises were then plentiful, and he could not resist eating them." The doctor says that salep made of orchis root is given in milk, and tells us in French that the root is a very remarkable one. I have gathered this plant often as well as most of the other beautiful native terrestrial orchises, but never saw such a harvest as Sir John Hill's criminal must have met with, when he ran mad with his belly full of orchis tubers. These orchis potatos would be worth the trouble to gather as medicine for the dull phlegmatic boys familiarly known by the *nom de guerre*, "Want of devil," with no force of character, who would not be at the trouble to do any harm, and could not think of the self-denial required to do any good. Now, if a meal or two of male-orchis roots would only rouse such boys into the region of vivacity, how it would delight their mothers' hearts to see them capering! But, joking apart, what faith could any sane person have in such writings as these? What I want to see in such books are the truthful opinions of practical men on things as they are, and not the transcribed nonsense of other days.

I could honestly name a very homely tree whose supple twigs have mended the manners of many boys, and could back my assertion with Scripture; for a birch rod seen in repose, as it hangs on the walls of a school, is a "terror to evil-doers;" but when it is put in motion, woe betide. This, indeed, were a rod worthy of all praise.

The third class of quacks consists of the old crones who have an idea that, if the medicine is only vegetable, it will be mild in its action and safe. I have gone into the herb market here, and bought herbs for the purpose of getting at the literature of the craft, to see what cer-

* Reprinted from the *Gardeners' Chronicle.*

tain herbs were called, and for what complaints they were reputed to be a remedy. I found none of the herb vendors so well up in the business as to know the botanical name of any one article that they sold, and many of the English names were such as have not been heard out of Lancashire lately. When any plantsman looks over the stock, and sees deadly poisons sold by the handful or even armful, and never by weight or measure, and with no reliable instructions as to the dose for an adult or for a child, the whole thing appears quite alarming. The business of the apothecary is regulated by law, and he qualifies for it; but the herbalist dispenses medicine in open market to all comers with impunity. I would not be severe upon the kindly old lady who sits by her herbs and roots all day long, and every market day, giving advice free, and charging very little for the medicinal herbs; but who can tell what fearful effects may be produced where excessive doses are given, and there is no duly qualified person ever called in to see the results? I have eaten the tubers of wake-robin (*Arum maculatum*), and know it to be an excellent vegetable, the tubers being beautifully white when boiled; but if I had eaten as much as the size of a bean of the same roots in a raw state I should have been poisoned. The whole secret of the *Arum* tubers is that the acrid principle is volatile, and goes off in boiling. In Thornton's 'Herbal,' above referred to, he speaks of doses of fresh *Arum* tubers of 10 grains taken inwardly, and that this very small dose (the 48th part of an ounce) makes the patient sweat. What a subject this fiery root would be for the herbalist to sell when fresh, while when dried or boiled it would be no better than a chip in porridge.

But strangers should come to Manchester at Whitsuntide to see the trade in nettles. Of this plant it has been said that it has dogged the footsteps of man everywhere to hang him, as it contains a strong fibre fit to make ropes of; but here it is made into beer, the liquor being sold at ½*d.* a bottle. When the scholars return from their yearly excursion to the country they come home laden with nettles; and were it not that every hair on the nettle is a poisoned sting, the plant would have become extinct long ago,—at least within thirty miles of Manchester. I have eaten the fresh nettle sprouts in spring, gathered before they got to be longer than one's finger, and they were very good plain boiled. If this practice were more common, it would lessen the crops of nettles, and turn this unhandsome plant to some good account. The public have nothing to fear from the herbalist making any mistakes in dispensing nettles. The plant has a character; there is nothing mawkish about it, and it needs very little logic to explain to the dullest comprehension that it will excite (Dr. Thornton agrees with this); indeed, I have seen lads dance with pain and without music when taking their first lessons on the nature and properties of a bunch of nettles. The dulness of the ass, the thickness of his hide, and the power of his jaw-bones, are all proved by the fact that he can eat nettles, green or dried, with impunity.

A lady lectured at Birmingham the other day on the education of women in the arts and sciences. Surely the botanical department of the "Materia Medica" would be a lady-like business, as there are already many ladies who are good authorities on our native flowering plants and ferns; and if the subject once got into a girl's school the pupils would collect the specimens, and when these were correctly named and described the girls would ever after know the plants by name, and be able to turn them to account. Reliable information on the nature and properties of culinary and medicinal herbs might from time to time be given in the columns of your valuable paper. Large sums of money are paid to herb-gatherers, and men may be seen fishing for the fleshy stems of water lilies (*Nymphæas* and *Nuphars*) and the bog hop, *alias* buckbean, *alias* water trefoil (*Menyanthes trifoliata*), and women employ themselves profitably by gathering wood sage (*Teucrium Scorodonia*), mugwort (*Artemisia vulgaris*) and horehound (*Marrubium vulgare*); and as these parties pay no rent for the land on which the herbs grow, it is by no means an unprofitable speculation.

There is a large field open for useful service in collecting, drying and preserving herbs. The herb teas are examples of leaves properly dried and preserved in canisters for use.

It may not be always easy to draw a hard and fast line between the duties of the housewife and those of the herbalist, for we read of the Scottish lady of rank superintending the manipulation of elder-flowers when she was asked in marriage to the Laird of Cockpen,—

"Lady Jane she was making the elder-flower wine;"

and Solomon's ideal of a household matron, a priceless treasure, is made to consist of a lady that looketh well to the ways of her household,—a worker,—or, as the sacred penman has it, one that eateth not the bread of idleness. Such an one would soon know plants by sight, and how to manage them.

NOTE ON THE DIGESTION OF MINERAL SUBSTANCES.*

BY RICHARD V. TUSON, F.C.S.

Professor of Chemistry in the Royal Veterinary College.

Physiologists and chemists have hitherto entertained the belief that the principal, if not the sole function of the pepsin and acid contained in the gastric juice is to render soluble the albuminoid constituents of food, and thus prepare them for the subsequent process of absorption.

Conceiving, however, that it would be extremely interesting to study the effect, if any, of the solvent constituents of the gastric juice upon mineral substances, especially those employed as medicines, I have set myself the task of investigating this subject. The inquiry is yet but in its infancy; nevertheless the results already obtained are sufficiently positive and striking to induce me to "claim date" by placing on record the following experiments:—

Experiment 1.—A mixture of calomel† and distilled water containing 2 per cent. of hydrochloric acid.

Experiment 2.—A mixture of calomel, pepsin,‡ and distilled water.

Experiment 3.—A mixture of calomel, pepsin, and distilled water, containing 2 per cent. of hydrochloric acid.

These mixtures were placed in glass vessels, and kept at 38° C. (100·2° F.), *i. e.* at about the temperature of the body, for twenty-four hours, during which time they were occasionally stirred or shaken. They were then thrown on to filters of Swedish paper, and the filtrates saturated with sulphuretted hydrogen. The filtrates from Experiments 1 and 2 remained unaltered. The filtrate from Experiment 3 yielded a precipitate of sulphide of mercury.

The results of these experiments therefore show that neither dilute hydrochloric acid (2 per cent.) nor pepsin alone is capable of dissolving calomel, but that when these agents are mixed they do effect its solution, and, consequently, that the digestion of calomel, so far as its solution in artificial gastric juice is concerned, is brought about under the same conditions as that of the albuminoids.

The importance of this observation will become appa-

---

* Reprinted from the *Lancet.*

† The calomel employed in all the experiments was previously tested as to its purity.

‡ Pepsina porci, prepared by Messrs. Bullock and Reynolds.

rent, when it is borne in mind that it offers an additional explanation to those already published of the manner in which calomel enters the circulation in order that it may exercise the many therapeutic actions with which it is accredited. Whether or not oxide of antimony, sulphide of antimony and other so-called insoluble remedies, are dissolved by pepsin and dilute acid, is a problem which remains to be solved. The influence of different acids, the chemical composition and characters of the dissolved mineral, and its behaviour when subjected to dialysis, also the action, if any, of peptones on inorganic bodies, have likewise to be determined; but these matters, together with many others, will form the subject of future communications.

THE ACTION OF PHOSPHORUS DISSOLVED IN CARBON DISULPHIDE ON A SOLUTION OF BLUE VITRIOL.

BY WERNER SCHMID.*

A clear solution of phosphorus in carbon disulphide, when shaken up with excess of a solution of pure cupric sulphate, yields a filtrate which acts but slightly upon solutions of silver, or upon an acidulated solution of potassic permanganate, thereby showing that it contains only traces of hypophosphite and phosphite. It acts, however, strongly upon litmus, cane-sugar, and ammonic molybdate, owing to the presence of free sulphuric and phosphoric acids.

The spongy voluminous precipitate is washed first with water, then with alcohol, and lastly with carbon disulphide, and pressed between bibulous paper. It dissolves only partially in highly-diluted hydrochloric acid. The solution is colourless, and becomes blue by being shaken up with ammonia only in the presence of air. This shows the presence of a cuprous compound. Concentrated hydrochloric acid likewise dissolves the precipitate merely partially, yielding a brownish-yellow solution which turns blue with ammonia in presence of air, and reduces ammonic molybdate to an intensely azure-blue solution. The latter is decolorized by nitric acid, and yields a yellow precipitate. On treating with concentrated nitric acid, the spongy precipitate dissolves completely with evolution of nitric oxide and formation of cupric sulphate and phosphate. Fusion with saltpetre effects the same. Sodic hydrate evolves non-spontaneously inflammable phosphine. It follows from all these observations that the precipitate consists of cuprous oxide, cuprous or cupric sulphide, and phosphide. Minute scales of metallic copper were observed only when the solution of the copper salt was allowed to float quietly on the phosphorus solution, although no metallic copper could be detected in the precipitate.—*Journal of the Chemical Society.*

PREPARATION OF HYDROCHLORATE OF CREATININE FROM URINE.

BY R. MALY.†

A few litres of human urine are evaporated to about one-third of the original volume, and the liquid, after being decanted from the salts which crystallize out, is precipitated with lead acetate. The filtrate is freed from lead by sodium carbonate or sulphuretted hydrogen, and after having been neutralized, either with acetic acid or sodium carbonate, precipitated with mercuric chloride. The precipitate, a combination of creatinine with the mercury salt, is decomposed under water with sulphuretted hydrogen, and the liquid, after treatment with animal charcoal, is evaporated. On crystallizing the crystalline residue once or twice from alcohol, pure creatinine hydrochloride is obtained in white crusts or hard shining prisms. The same results were obtained with horses' urine.—*Journal of the Chemical Society.*

ACTION OF HYDRACIDS ON THE QUININE ALKALOIDS.

BY W. ZORN.*

When cinchonine sulphate was heated in sealed tubes with concentrated hydrochloric acid for some hours to 140°–150°, the contents of the tubes yielded on evaporation crystals not unlike those of cinchonine sulphate, but differing therefrom essentially in their insolubility in acids. After one recrystallization these crystals do not contain a trace of sulphuric acid; their solution is strongly acid, but is no longer fluorescent. They are anhydrous. Chlorine determinations prove that they contain three atoms of chlorine, two of which are readily and completely removed by silver nitrate, the third with difficulty. The mother-liquor from the above crystals yields on further evaporation a second crop of different aspect, but also free from sulphuric acid.

Quinine sulphate similarly treated gives crystals, which also do not contain any sulphuric acid; these yield a strongly acid solution, which is non-fluorescent, and coloured only very slightly green on addition of chlorine water and ammonia. Potassium ferrocyanide produces a yellow precipitate, insoluble in excess, but soluble on boiling. The base is precipitated by ammonia, and is readily soluble in ether, also in an excess of ammonia and in boiling water. In its behaviour with ammonia and chlorine-water, and with ferrocyanide, this new body resembles cinchonine; like quinine, it is readily soluble in ether, but differs from both by its solubility in ammonia and in boiling water.

By the action of hydriodic acid on cinchonine sulphate, products are obtained, the examination of which, and of the above, the author is prosecuting.

THE EMULSION OF VEGETABLE TAR AND SAPONIN.

M. Lucien Lebœuf, in a paper published in the *Journal de Pharmacie et de Chimie*, recommends the formation of an emulsion of vegetable tar by means of saponin as a means of obviating the difficulty met with in the administration of that medicament, arising from its slight solubility in water. A tablespoonful (20 grammes) of such an emulsion containing 2 per cent. of tar would represent 0·40 grm. of tar, that is to say, the quantity contained in a litre of the hydrolate of tar of the Codex. By the addition of a little sugar the acridity of the tar is covered, and the mixture is rendered palatable.

Saponin, being a neutral substance, exercises no chemical action upon the tar, while the quantity required to effect the emulsion, about 1 part in 500 of such a preparation as that described above, is so small that M. Lebœuf considers its possible effect upon the system would be so slight as to make it unnecessary to take it into account. It is suggested that this new pharmaceutical preparation of tar, diluted more or less with water or glycerine, might be used with facility in lotions, injections and gargles, etc.

THE CHICAGO COLLEGE FUND.

The following is a list of the subscriptions promised up to December 20th.

The Members of the Chicago College of Pharmacy, notwithstanding their own great losses, will themselves provide a new building. Their appeal is solely for donations of articles for the Library, Lecture-Room and Museum. English Pharmacists, unable to give books, etc., are invited to send subscriptions of money, the whole of which will be expended by the Committee in the purchase of appropriate contributions.

Parcels of Books, Specimens of Chemicals, or Articles of the Materia Medica, Apparatus and Subscriptions may be sent to Professor Attfield, 17, Bloomsbury Square, London, W.C. Cheques, crossed "London and Westminster Bank," and Post-Office Orders, drawn for "High Holborn," may be made payable to John Attfield. All Donations will be acknowledged in the Pharmaceutical Journal.

Amount previously acknowledged, £99. 8*s.* 6*d.*

SATURDAY, DECEMBER 23, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

APPRENTICESHIP AND THE PRELIMINARY EXAMINATION.

FEW things are more difficult than to maintain the interest of a discussion in which the arguments all proceed from one side. Even that accomplished controversialist, Mrs. CAUDLE, who so well understood the art of relieving her matrimonial opponent from the cares of a reply by keeping her own tongue continually going in the frequent reiteration of what she had to say, was often mortified to find that the only result of such one-sided eloquence was, that Mr. CAUDLE—slept! There may be a danger of a similar effect upon our readers from a recurrence at so short an interval to the subject of Apprenticeship and the Preliminary examination. But our apology is to be found in the recently published Report of the Board of Examiners on the Preliminary examinations conducted by them during the past year, together with the additional testimony of an experienced teacher to the same effect in our columns this week, telling of such absolute ignorance in some of the candidates, and such lack of sound education in others, that one wonders how they came to waste their time and money in presenting themselves for examination.

The most serious aspect of the evil is that many of these incapables are already connected with the business by ties of apprenticeship. That a youth should have been bound to a calling, and have devoted more or less time to it, before finding himself unable to pass the first test of his fitness for entering it, is a pitiable occurrence, and one that promises ill for his success in satisfying the requirements of the law before he can practise it with profit or credit to himself. To such youths, however, the greatest goodwill has been shown by pharmaceutists throughout the country, and if they are as ready to help themselves as the different Associations appear to be willing to aid them, a few years' hard work will greatly improve their position.

What shall be done with regard to apprentices in the future? It is on the practical answer given to this question that the future status of pharmaceutists will depend. And here the interests of the public, the employer, and the candidate for apprenticeship are at one. That it should be possible for the dispensing of prescriptions to be entrusted to persons capable of giving such grotesque renderings of the Latin directions as those instanced in the Examiners' Report, is not a very comforting fact for the public, who are liable to be poisoned, or the employer who may be ruined in payment of damages. It may be supposed that the instances were exceptional; such, however, is probably not the case. We are ourselves in almost daily receipt of communications from this class of persons, which, from the evident utter inability of the writers to comprehend the rudiments of Latin, English, chemistry, or anything else, are perfectly bewildering and impossible to understand.

But what should be the answer to the question we have put? Respecting this, there is in theory perfect unanimity, namely, that no apprentice should be indentured before he has passed the Preliminary examination. This answer has now received the official endorsement of the Board of Examiners in presenting, and of the Council in receiving, the recommendation contained in the Report. Such being the case, we hope the practice will be in accord; and that, although there will doubtless be exceptions through an injudicious inability to say "No," or a too eager hankering after a premium, it will henceforth be the rule for pharmaceutists to ensure, as far as possible, good and intelligent service from their apprentices by requiring them to have passed this preliminary test with credit.

MINERAL SPRINGS IN JAPAN.

A FEW interesting particulars relative to some mineral springs in Japan are given by Mr. TROUP, in his account of a short tour made by him in that country, which has recently been issued as a Parliamentary paper. He says that the sulphur springs at Numajiri, in the province of Iwaskiro, present probably a phenomenon that could not be found in any other part of the world. The springs, which are approached by a somewhat difficult mountain road, are several in number, and combine to form what is literally a mountain stream of hot sulphur-water. The breadth of the stream may be stated as from two to three yards, though in running over a stony bed it spreads out in some places over a greater space. Immediately below the springs a rich deposit of yellow mud is formed; but in the main stream the deposit assumes more of a greenish tinge. Several miles below the springs, after the stream has mingled with other mountain streams, with which it runs into the lake of Inawashiro, the water still retains a very perceptible sulphurous smell and taste.

At Oshiwo, in the same province, there are two salt springs of tepid water. The manufacture of salt is there carried on by simply evaporating the spring water in pans placed over wood fires. The salt so obtained is much whiter than the ordinary Japanese salt, being nearly equal in colour to

English table salt. Only a small portion of the water, however, is so used, the bulk of it being allowed to run into a neighbouring stream.

At a recent meeting of the Agri-Horticultural Society of Madras, a reference was made to the medicinal properties of *Spilanthes oleracea*, especially as to its use as a remedy for toothache.

Colonel Pears, who communicated the fact, says that it was administered on the recommendation of a native servant to a friend of his who was suffering from very severe toothache, and that it effected a perfect cure in a very short time. Dr. Hunter pointed out that the *Spilanthes* contains some acid principle, and, when chewed, causes a copious flow of saliva. The use of such articles for the relief of toothache is of very ancient date in European medicine, the pellitory of Spain having long been used as a masticatory in cases of toothache. The *Spilanthes* is probably just as effectual as the pellitory, and is, moreover, easily obtained in India.

The plant, which belongs to the *Compositæ*, is an erect, branching annual, growing about 12 or 14 inches high, and having small yellow flower-heads at the ends of the branches. It is well known for the peculiarly pungent taste of its leaves, on which account it is frequently cultivated in some tropical countries for use as a salad and pot-herb. It is known as Pará grass; in Japan it is called Ho Ko So.

A correspondent of the *Leavenworth Journal of Pharmacy* reports the result of an examination of a specimen of opium, purchased from a wholesale house which boasts that the opium sold by them is selected by their agent at Smyrna. One pound and a half of the opium in question was found to contain four ounces of gravel mixed with a few particles of iron pyrites.

It is stated in a recent number of the *Birmingham Morning News* that injurious results have followed the use of a disinfectant supplied to the town of Wolverhampton by its authorities, and conjectured to contain carbolic acid. In one establishment where it was used, we are told that the sickness of three men is attributed to the disinfectant, as well as the death of two valuable dogs.

A series of coloured photographic illustrations of interesting cases occurring in the practice of the British Hospital for Diseases of the Skin is to be published by subscription, in furtherance of one of the objects for which the hospital was established, viz. "the diffusion of knowledge regarding the diseases of the skin." The work will be under the superintendence of Mr. Balmanno Squire, and will be issued in quarterly parts.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Fifth General Meeting was held at the Royal Institution on the 7th inst.; the President, Mr. E. Davies, F.C.S., in the chair.

Mr. J. Simpson, 10, Rumford Place, was elected a member of the Association.

Donation of the current numbers of the Pharmaceutical Journal was announced.

The President read a circular he had received from Dr. Attfield, asking for aid in replacing the loss sustained from fire by the Chicago Pharmaceutical College. The President said he had been named one of the committee formed to promote this object, and he should be glad to receive contributions of money, books or objects for the Museum.

Mr. Samuels showed a new and simple contrivance to note hygrometrical changes in the atmosphere, called "the Chameleon Barometer."

Mr. Fraser then read a paper entitled "Notes on Practical Pharmacy," in which he mentioned his experience in testing for morphia in opium; and in speaking of the value of the B. P. test said, that although when worked carefully it would give true results, yet it was just possible that, with hurried work, a part of the morphia would be separated along with the colouring matter, thus giving the percentage too low. In any case the morphia is brownish from the presence of colouring matter. For the purpose of checking this test, he used the method known as Staples', in which the morphia is precipitated from an aqueous solution, to which alcohol has been added, by ammoniacal spirit; this gives almost colourless crystals. These two processes, carried on simultaneously, he considered to be sufficient for all practical purposes. Mr. Fraser next treated on the advisability of having a hard and fast standard for the quantity of morphia which shall exist in the official opium preparations. Lastly, he advocated the question, whether we ought to standardize other drugs according to the percentage of the alkaloid or active principle; and he expressed an opinion that these, from a medical point of view, will be more satisfactory remedial agents than either the system now in use or the substitution of alkaloids. In conclusion, the new process for preserving and seasoning wood by means of boiling in a solution of borax was briefly noticed.

A discussion followed, in which the President, Mr. Tanner, Dr. Symes and Mr. Fraser took part.

A vote of thanks to Mr. Fraser for his paper was then passed.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The Fifth Ordinary (fortnightly) Meeting of the session was held at Mitre Chambers, December 12th; the President (Mr. Lane) in the chair.

A paper was read by Mr. Gill, on "Starch."

After a short general introduction, the reader proceeded to treat—first, of starches used in the arts, viz. wheat, potato and rice, and describing their different methods of production; afterwards, those used as articles of diet, as arrowroot, tapioca, tous-les-mois, etc., with their sources and modes of preparation.

The various tests were given practically, and the different varieties of starch-granules shown under the microscope.

These illustrations were very instructive, and added considerably to the interest of those present. The next meeting is arranged for January 9th, 1872, when a paper will be read on "Cinchona Barks," by Mr. Ridley.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

At the Meeting of this Society, on Thursday, December 7th, Professor FRANKLAND, F.R.S., in the chair, Dr. J. H. Gladstone, F.R.S., read a paper on "Essential Oils," in continuation of one read before the Society eight years since. As we may have an opportunity of printing this paper in full on a future occasion, at present we only give a brief abstract. The first group of oils described included citrin, lign aloe, pimento, and oil of villvert. The hydrocarbons from essential oils were divided into three polymeric groups, having the formulæ $C_{10}H_{16}$, $C_{15}H_{24}$, and $C_{20}H_{32}$, and the line of demarcation observed in comparing their physical properties pointed out.

Many of the essential oils are mixtures of a hydrocarbon with a compound containing oxygen, of which but few have hitherto been carefully examined. Those obtained from citronella and from wormwood the author calls citronellole and absinthole respectively: they both have the composition $C_{10}H_{16}O$, the most remarkable point of difference between them being in their refraction equivalents; that of absinthole being 74·5, which agrees closely with the theoretical for $C_{10}H_{16}O$, while citronellole has 79·3 or 79·8 for its equivalent, a discrepancy almost the same as that found throughout the great phenyl group. Besides these he has examined cajeputole from oil of cajeput, and also the two carvoles from oil of caraway and oil of dill. These appear to be identical and not merely isomeric, and are remarkable for forming a crystalline compound with sulphuretted hydrogen having the composition $(C_{10}H_{14}O)_2H_2S$. The physical properties of menthole from spearmint, myristicole from nutmeg, and hydride of cumanyl from cassia, have likewise been examined; the latter has the enormous refraction of 1·6045 for the line A, and its refraction equivalent is also very abnormal.

In the discussion that followed, the PRESIDENT said that the paper which Dr. Gladstone had communicated to the Society was one of great importance, since these physical qualities were facts which would remain unalterable however much our views as to the theory of their constitution might change, and although no one admired this class of investigation more than he did, he might also be allowed to speak a word in favour of certain chemical reactions which might, perhaps, enable us to relegate these hydrocarbons to their proper families, such as the action of chlorine or bromine on them. He should like to elicit from the author if he had tried any such reaction, so as to distinguish, for example, whether they were hydrides or radicals.

Dr. GLADSTONE said that bromine and chlorine derivatives had been prepared, but that the result had been unsatisfactory.

Dr. WRIGHT asked whether his researches had led the author to consider the hydrocarbons as isomeric in the same way that the butylic hydrides are, or was it possible that many of these hydrocarbons might be identical, the difference in their properties being due to accidental impurities.

Dr. GLADSTONE replied that these oils were distinguished in some cases chiefly by their optical properties, and in others by their odour: citronellole was distinguished from absinthole by the former having a considerably higher refractive equivalent than the theoretical, like that found in compounds throughout the great phenyl group; and again, the carvol from dill and the carvol from caraway were considered to be identical and not isomeric, from having the same odour; the same might be said of the eugenic acid from pimento and from cloves; identity of odour alone, however, is not sufficient to establish the identity of the hydrocarbons.

Dr. WRIGHT suggested that the odour might be due to a chemical change which the substance undergoes in the presence of oxygen, and in contact with the mucous membrane of the nose. It was well known that hydrocarbons which had been recently distilled over sodium had a less powerful odour than they had after being exposed for some time to the air.

Professor A. H. CHURCH referred to the very interesting sulphur compound $(C_{10}H_{14}O)_2H_2S$, in which an oxidized oil was united with sulphuretted hydrogen. Some eight or nine years ago he had described tasmanite, a resin found in a shale from Tasmania, which contained oxygen and sulphur in the same relative proportions as the above-mentioned compound. This resin, when treated with sulphuric acid, evolved sulphuretted hydrogen, so that the sulphur was in organic union with it, and not like the sulphur found in coal. In another fossil resin, dysodile, which he had examined, the sulphur and oxygen only approximated to that ratio, but then it was not pure.

Dr. H. E. ARMSTRONG then read a paper entitled "Observations on Nitrochlorophenols."

SOCIETY OF ARTS.

DYES AND DYE-STUFFS OTHER THAN ANILINE.*

BY DR. CRACE-CALVERT, F.R.S.

LECTURE III.

Blue Colouring Substances.—Indigo, Orchil, Cudbear, Litmus, Prussian Blue and Ultramarine.

(*Continued from page* 496.)

The carmines of indigo are especially used by silk-dyers, in consequence of the removal of the green colouring matter above referred to, and which, if allowed to remain, would spoil the blue or purple which they wish to obtain. The method practically adopted to ascertain if the sample has been well washed, consists in rubbing a small quantity of it on a piece of glazed paper, which, when the colour dries, gives a colour varying from a pale blue to a rich copper purple, according to the mode of manufacture; and if any green colouring matter is left in, it shows itself as a green ring round the blue circle.

The following may be taken as the composition of a sample of carmine of indigo of fair quality:—

Water	85
Indigo	10·2
Saline residue	4·8
	100·0

The sulpho-indigotic acids are especially used by woollen-dyers, who add to the dye-beck a little alum and cream of tartar, which helps the fixing of the indigo on the wool. The green colouring matter is in this case not objectionable, having no affinity for the fibre of wool.

The carmines of indigo, as well as the sulpho-acids, are easily decolorized by reducing agents, such as hydrogen and sulphuretted hydrogen, but they gradually reassume their original colour when exposed to the atmosphere, through the absorption of oxygen.

The above compounds, not being suitable for dyeing cotton, and not giving colours on silk and wool that may be considered fast, I shall now proceed to describe a few of the methods followed to obtain fast indigo blues. They are all based on the principle of the reduction of blue indigo into white indigo. The latter compound is held in solution by an alkali, which enables the dyer or printer to introduce it into the fibre of the fabric, where, on exposure to the atmosphere, the alkali combines with carbonic acid, and the white indigo thus liberated absorbs

* Cantor Lecture, delivered Tuesday, Feb. 21. Reprinted from the *Journal of the Society of Arts.*

oxygen, and becomes insoluble blue indigo. The principal class of goods to which this chemical reaction is applied is to the vegetable fibres, linen and especially cotton. As far as dyeing is concerned, the processes can be classed under two heads, hot and cold. The hot process is principally applied to wool, the cold to vegetable fibres, especially cotton.

The oldest and still most generally employed method of preparing cold vats consists of putting into a vat containing about two thousand gallons of water, sixty pounds of indigo, very finely powdered, one hundred and eighty pounds of slaked lime, and one hundred and twenty pounds of sulphate of protoxide of iron or green vitriol (free from any trace of copper salt), the two latter substances being added from time to time. The greater part of the lime used unites with the sulphuric acid of the iron salt, to produce sulphate of lime or gypsum, and the liberated protoxide of iron removes the oxygen from the indigo, becoming converted into saline oxide, whilst the reduced indigo dissolves in the excess of lime employed.

Messrs. R. Schloesser and Co., of Manchester, have introduced within the last year or two a marked improvement in the preparation of cold vats, which removes the great objections of the bulky precipitate of sulphate of lime, the formation of an oxide of iron, and the loss of indigo by its combination with the oxide of iron referred to in the previous part of the lecture. The bath remaining much more fluid, the pieces are less apt to be spotted, and a better class of work is produced. To carry out their process, they add to the ordinary two thousand gallon vat twenty pounds of ground indigo, thirty pounds of iron borings, thirty pounds of their remarkable powdered zinc, and thirty-five pounds of quick lime; the whole is stirred up from time to time for twenty-four hours, when it is ready for use. If the bath is not considered sufficiently strong, a little more lime and zinc are introduced.

The chemical theory of the process is, that the zinc, under the influence of the lime, decomposes water, combining with its oxygen, and the hydrogen thus liberated removes oxygen from the indigo, which then dissolves in the lime.

To dye cotton yarn in the above vats, it is simply necessary to dip it for a few minutes in the dye-bath, and expose it to the atmosphere, when the green hue it has acquired passes rapidly into blue. This operation is repeated until the yarn has attained the required depth of shade, when it is passed into weak vitriol, washed, and is ready for market.

To dye calicos, the pieces are hooked on frames, passed through a bath of weak milk of lime, and then dipped into the reduced indigo vat. After fifteen minutes, the frame is taken out and the cloth exposed to the air for about the same length of time. It is again dipped, the process being repeated until the required depth of tint is attained. It is then passed through weak vitriol, and washed. The cold vats are especially used when it is wished to obtain white and yellow designs on a blue ground; but when the object in view is to produce a self-colour, a more rapid process is adopted. This consists in passing the pieces through a dye-beck, then through an acid liquor, and lastly in water, by means of rollers fixed in the vat. The bath is composed of lime, sulphate of iron and indigo, but is kept hot, instead of cold as in the former case.

There is still another process, which is now used to a limited extent only, but was at one time very extensively employed. It produces on the cloth a pale blue, which has a great similarity of tint to that seen on the china porcelain, from which it derives its name of china-blue. To produce it the pieces are printed with a mixture containing very finely-powdered indigo and a little acetate of iron, and are made to pass through six successive vats. The first two contain lime, the third sulphate of iron, the fourth a solution of caustic soda, the fifth a dilute solution of sulphuric acid, and the sixth water. When the design has acquired the required depth of blue, the pieces are washed, passed once more through weak sulphuric acid, and again washed. The chemical reactions are exactly similar to those in the cold vat process.

For dyeing wool, a modification of the old woad vat is employed. The use of woad being now almost entirely discontinued, I shall merely call your attention to the process in which indigo has been substituted for woad. It bears the name of Indian vat, doubtless from the process having been practised in India and imported from thence. It is as follows:—Eight pounds of powdered indigo is added to a bath containing $3\frac{1}{2}$ pounds of bran, $3\frac{1}{2}$ pounds of madder, and 12 pounds of potash, which is maintained for several hours at a temperature of 200° F. It is then allowed to cool to 100° F., when fermentation ensues. After about forty-eight hours, the indigo is rendered soluble, being reduced by the decomposition of the sugar and other products contained in the bran and the madder-root during the process of fermentation. The bath should have a greenish-yellow appearance, having a frothy scum of a blue coppery hue.

Of late years, improvements have been made in this class of vats, by which the expense of using madder is avoided. They are now prepared by adding to water, at a temperature of 200° F., twenty buckets of bran, twenty-six pounds of soda crystals, twelve pounds of indigo, and five pounds of slaked lime. After five hours, the bath is allowed to cool to 100° F., when fermentation ensues, and the indigo is dissolved in the alkali. The management of these vats requires great experience and care, for if the fermentation is too slow the indigo is not properly reduced, whilst if too active large quantities of indigo may be lost. The researches of Dr. Schunck, already referred to, not only show the method of avoiding this loss, but explain why it occurs. The remarks which I made as to the causes of failure in the manufacture of indigo are applicable here, namely, that if the fermentation becomes alcoholic and acetic, the non-oxidizable indigo compounds described by Dr. Schunck are generated.

I cannot leave the subject of indigo without bringing before you a most curious source of its production, namely, the human body. Medical men had observed from time to time that urine, secreted under certain pathological conditions, became brown, and sometimes even blue, when exposed to the atmosphere. The late Dr. Hassel discovered that in some instances the colouring matter was indigo, but here, again, we are indebted to Dr. Schunck for much information on the subject. In three papers presented to the Royal Society, he has proved that urine, in cases similar to those examined by Dr. Hassel, contained the glucoside of indigo, or indican. He also observed that indican was a very frequent constituent of urine secreted by persons in a healthy state, and, in fact, that it is produced generally when persons do not take sufficient exercise, and he has on several occasions succeeded in producing it by taking in his food a rather large excess of sugar.

Orchil, Cudbear, Litmus.—I shall now call your attention to a colour which was discovered in 1300, by an Italian named Federigo, who, during his travels in the East, observed the tinctorial powers of a certain class of weeds called *lichens*, and he introduced the colour into Florence under the name of *orchil.* By this discovery he and his family made a very large fortune.

Lichens are small plants which live either in the stems or leaves of trees, or on rocks, or damp soils. To this class belongs all the vegetation found in the Arctic circle, but the species growing there are not employed to produce the colouring matter orchil, the varieties used for this purpose being found in warmer, and especially in tropical climates. These latter can be divided into two classes; the first and most abundant, which grow on rocks near the seaside, includes the species *Roccella tinc-*

toria and *Rocella fuciformia.* They are obtained from the Canary Islands, Cape Verde and Sardinia, but principally from Madagascar, Zanzibar, Angola and South America. The second class grows inland, and includes the species *Variolaria orcina*, found especially in the Pyrenees.

Lichens do not contain any colouring matter already formed, but contain colourless acids, which, under the influence of ammonia and the oxygen of the atmosphere, give rise to the orchil. As the lichens imported into this country vary considerably in the amount of orchil which they yield, Dr. Stenhouse has rendered a great service to the manufacturers in furnishing a simple and accurate process of ascertaining their commercial value. The following is an outline of his method:—One hundred grains of the lichen are macerated with a dilute solution of caustic soda, two treatments being sufficient to extract the whole of the colouring matter. A solution of hypochlorite of sodium of known strength is added to the soda solution from a graduated alkalimeter; the moment the bleaching liquor comes in contact with the soda solution of the lichen a blood-red colour is produced, which disappears in a minute or two, and the liquid has only a deep yellow colour. A new quantity of bleaching liquid should then be poured into the soda solution, and the mixture carefully stirred. The operation should be repeated as long as the addition of the hypochlorite of sodium causes the production of the red colour, for this shows that the soda solution still contains unoxidized colouring principle. Towards the end of the process the bleaching solution should be added by only a few drops at a time, the mixture being carefully stirred between each addition. By noting how many measures of the bleaching liquor have been required to destroy the colouring matter in solution, the amount of colouring principle contained in the lichen may be determined.

The manufacturers of orchil are also indebted to Dr. Stenhouse for a process of obtaining the orchil, which, besides simplifying the operations required, gives brighter colours and extracts than could be produced before the publication of his method, in 1848. Of this you will easily judge when I tell you that the process carried on for centuries consisted in breaking up the weeds in water, to which putrid urine, lime and carbonate of soda were added from time to time. After two or three months' exposure to the air, the colourless principles of the lichen became transformed into the colouring matter orchil. As the science of chemistry progressed, and cheap means of producing ammonia were devised, this compound was substituted for the urine. Dr. Stenhouse's process consists in exhausting the lichens, by macerating them with milk of lime, squeezing the liquor off, and after having repeated this treatment two or three times, he adds an acid to the liquors, when a white gelatinous precipitate is produced, which, when collected and placed in contact with ammonia, gives rise to orchil.

You are doubtless aware that the beautiful purple and mauve colours obtained on silk and wool from orchil are extremely fugitive, losing their brilliancy on exposure to the light or to the influence of weak acids, such as sulphurous, which is so abundantly produced in our manufacturing districts. M. Marnas, of Lyons, succeeded in the year 1856, in making orchil colours which gave fast purples and mauves.

Before describing this valuable discovery, allow me to state that it had a most important bearing on the marked progress which the art of calico-printing has made since the date above mentioned. Until that time, neither dyers nor calico printers would use expensive dyes, but since then they have paid as much as £40 or £50 per pound for the solid dyestuff, although these enormous prices have been apparently decreased by the colours being sold in the state of paste or solution.

The demand for a fast purple in this country was so great, consequent on the introduction of the fast purples and mauves on the Continent by M. Marnas, that attention was directed to the preparation of these colours. Mr. Perkin had obtained from aniline a fine purple colour, as fast as the orchil colours, and M. Bechamp discovering about this time a method of producing aniline artificially from benzine, Mr. Perkin was enabled to manufacture his colour commercially. This may be considered as the first successful step towards the introduction of the spendid and varied coal-tar colours which are now so universally admired.

(*To be continued.*)

Parliamentary and Law Proceedings.

A Disputed Claim.

At the Shrewsbury County Court, held on Monday, December 4, before Judge Smith, Thomas Andrews, who alleged that he was a doctor of medicine, sued Frank Harry Davies for £4. 13*s*. 6*d*. Mr. Morris appeared for the plaintiff, and Mr. Chandler for the defendant. The case was a peculiar one, both from the nature of the claim and the defence set up to meet it, and was of considerable importance to the medical profession in the town.

Mr. Morris said the plaintiff in this case is Mr. Thos. Andrews, who was, until the 22nd of February, a chemist and druggist only, carrying on business in Theatre Buildings. Since that time he has, by medical examination and not by a purchased degree, either abroad, in London, in Edinburgh, or elsewhere, been certified as a doctor of medicine. This bill, for which the defendant is sued, was incurred before Mr. Andrews passed, and he is therefore only entitled to charge as a chemist and druggist.

Thomas Andrews, the plaintiff, was then called into the box. In answer to Mr. Morris, he said—I am the plaintiff in this case, and at the time this bill was incurred I was carrying on the business of a chemist and druggist. I have now passed as a doctor of medicine, but in the bill, which was prior to my doing so, I have only charged as a chemist and druggist for medicine supplied.

The bill was handed up to his Honour, and was as follows:—

"Shrewsbury, November, 1871.

"Mr. Frank Harry Davies

"To Thomas Andrews, M.D.

"To professional attendance, medicine, etc., £4. 13*s*. 6*d*."

Mr. Chandler: You hold a diploma; have you got it with you?

Mr. Andrews: I have not.

Mr. Chandler: Will you kindly tell me what kind of a diploma it is?

Mr. Andrews: It is a foreign diploma.

Mr. Morris: Your Honour, he is not charging upon the principle of having a diploma at all.

Mr. Chandler: But it is a matter of what he says in his bill-head. This says, "To Thomas Andrews, M.D. To professional attendance, medicine, etc. etc."

Mr. Morris: I object to this. We are only charging for medicines.

Mr. Chandler (to Mr. Andrews): I am asking you where you got your diploma from.

Mr. Morris: It does not matter where he gets his diploma from.

The Judge: The only question is, Mr. Morris, do you want the case adjourned to alter your bill of particulars?

Mr. Chandler: He charges us here as if the bill were from a medical man. I merely want to ask him where he obtained his diploma from.

In reply to this and several similar questions from Mr. Chandler, the witness would give no further description of the diploma than that it was an American one, and reiterated that he was not charging as a medical man. The bill-head had been made out by an assistant, since his examination.

The Judge suggested that the case should be adjourned, in order that the plaintiff might give particulars of his claim and amend his bill.

This course was strongly objected to by Mr. Chandler on behalf of the defendant. He said they wanted no better particulars; the inference was that the bill was a professional man's bill. Plaintiff came there as a medical man; if he were such, he would be on the register, and defendant would have no answer; if not, why was defendant brought there? He denied that he was instructed by any other person than the defendant, and objected to the proposed course, even if the expense was borne by the plaintiff.

The Judge, however, considered that the right course would be to give the plaintiff an opportunity of amending his particulars; and, in spite of a vigorous protest from Mr. Chandler, the case was adjourned for that purpose.

Poisonous Christmas Cakes.

On Friday night, December 15th, Professor Thorpe, of Anderson's University, Glasgow, while passing a pastry baker's shop near the centre of the city, observed in the window a Christmas cake garnished with a suspicious green-coloured substance. He purchased the cake, and, on analysis, discovered that the green tint was produced by arsenic. On the following day the Professor's assistant purchased two cakes similarly coloured. The police were informed of the circumstances, and on the shop in question being searched, another cake of the same description was found. The proprietor of the shop admitted that he had painted part of the sugar ornamentation with what is called "emerald green," which he purchased in a drysalter's shop in the city. He was taken into custody on Saturday night, pending inquiry.

Poisoning by Lucifer Matches.

On Friday, December 8, a very distressing event occurred at Dalton Green, near Huddersfield, namely, the poisoning of a child through eating lucifer matches. The child was between two and a half and three years old, the daughter of Mr. John Hutchinson, traveller. On Friday morning she went to play, and at noon, when having dinner, she began to vomit. As the food left her stomach the smell which is perceptible after a match has been struck was noticed. It was at once thought that the child must have been eating matches, and the mother proceeded upstairs, when she found that a large number of matches had been spilled on the floor, and it became evident the child had been playing with them. Between two and three o'clock the child was taken to Dr. Scott, York Place, Huddersfield, where an emetic was administered; and he recommended that she should be taken to the Infirmary to have the stomach pump applied. The child was taken home and grew worse. Its grandmother imagining that she was suffering from inflammation of the lungs, treated it for that complaint, but the treatment did it no good, and some time after tea Dr. Booth was sent for. Dr. Booth attended, but in the meantime the child had died.—*Leeds Mercury*.

The Poisoning Case at Hoxton.

On Monday, December 19, Mr. John Humphreys, the Middlesex coroner, resumed the investigation respecting the alleged murder of William Dent Russell, aged seven months, who was supposed to have been wilfully killed by poison.

The evidence of Mrs. Amelia Russell proved that the deceased was her son, and that she lived at 8, Rahere Street, Goswell Road. She was the wife of a cabinetmaker, named William Dent Russell. On Monday fortnight her son became ill, and her husband said that he hated to hear it cry. She, therefore, bought a cough mixture to prevent its crying. She got the mixture at Mr. Hodaile's, a chemist, in Cross Street, Shepherdess Walk. On Monday, Tuesday and Wednesday she gave the deceased some of it, and it did him good. On the following day, Thursday, she gave the child some of the mixture and he became ill, and she ran with him to her mother's. On the following Friday the child died. Her husband had been drunk on the Monday, but the following days he was sober. She could not tell how oil of vitriol got into the cough mixture. Only she and her husband had access to the locked coal cellar in which the oil of vitriol was kept. The cough mixture was kept in a cupboard in the sitting-room.

After some further evidence, the jury returned a verdict to the effect that the deceased was killed by the wilful mixing and administration of poison, but by whom the poison was mixed and administered there was no evidence to prove. The coroner said that was tantamount to an open verdict of wilful murder.

Suspected Poisoning by Antimony.

The inquest at Bilston, upon the body of a child whose death was suspected to have been caused by antimony, which has been twice adjourned to allow of the exhumation and examination of two other children, was resumed on Tuesday, Dec. 19. Dr. Hill deposed that he had detected the presence of antimony in the body of the third child, William Griffiths. This child died on the 10th of October, and the death was registered on the 13th of that month, the medical certificate attributing the death to "asthenia" and "gastric fever," six days. The surgeon deposed that he did not believe the mother carried out his instructions in respect of the diet ordered, and that his medicine had nothing like antimony in it.

The coroner having reviewed the evidence that had been given, the jury deliberated about half an hour and returned a verdict of "Wilful Murder" against the accused in respect of all the three children, and she was committed for trial at the next Staffordshire Assizes.

Infringement of the Pharmacy Act.

The following case was heard before the Wrexham County Bench on Monday, Dec. 18th:—George Gibbons, of Adwy'r Clawdd, was summoned for having, on the 29th of November, unlawfully sold by retail two bottles containing poisons, laudanum and syrup of poppies, without either of the bottles being distinctly labelled with the name of the article and the name and address of the seller.

Mr. Acton, instructed by Mr. J. F. Edisbury, Local Secretary to the Pharmaceutical Society, appeared to prosecute, and Mr. J. A. Hughes appeared for the defendant. Mr. Hughes said his client admitted the offence.

Mr. Acton said the information was laid under the 17th section of the Pharmacy Act. The Bench would be aware that there was an Act passed for the regulation of the sale of poisons, by which persons not registered were only to sell according to certain precautions. It was a matter of considerable consequence, and he might be permitted to say that there was a machinery provided for that Act by the Pharmaceutical Society of Great Britain so that it may not become a dead letter. The offence was selling poisons without labelling them with the name and address of the seller, although the bottles were labelled "Poison," which it was important should be done, so that if anything went wrong they might know who was the seller.

In reply to Mr. Meredith, it was stated that this was the first offence of the nature in which proceedings had been taken in this district.

Mr. Hughes said his client bore a good character. For six or seven years he had been dispenser in the surgery of Dr. Williams, of Wrexham; and, subsequently, he was employed as an assistant to Dr. Davies. He regretted extremely to have to appear before the Bench. The offence charged was not of a very serious nature, the only offence being not having his name printed on the label; and he hoped the magistrates would mitigate the maximum penalty, which was £5.

Fined 40*s.* and costs, Mr. Meredith advising the defendant to be very careful in future.

Robbery by a Chemist's Assistant.

At the Newcastle Police Court, December 4th, James Marlee, 19 years of age, was charged with stealing £25, belonging to his master, Mr. Boe, chemist, Hinde Street, Scotswood Road; whilst a woman named Isabella Pearson, aged 30 years, was charged with receiving the money, knowing it to have been stolen. It appeared that on Monday the prosecutor sent Marlee with £25 and the bank book to Messrs. Hodgkin, Barnett, Pease and Co.'s bank to deposit the money, but he never returned to the shop. Information was given to the police, and on inquiries being made it was found that he was cohabiting with the female prisoner, who is a married woman, but living apart from her husband. It was also ascertained that they had taken part in furnishing a house in Wellington Street. Detective-officer Fawcett traced them to this house, and found them there, about half-past twelve o'clock at night. Marlee was concealed in an inner room, with the door fast on the inside, when the officer entered the house, but shortly afterwards he was apprehended and sent to the police-station. Fawcett searched the house, but could not find the bank book or the money, and the woman denied having any knowledge of the robbery. About two o'clock in the morning, Fawcett, accompanied by Superintendent Dixon, returned to the house and a second search was made, during which Pearson pointed to the bank book, which was lying in the place that had been searched before. In a water closet they found a purse containing £2. 13*s*. The officers then took the woman into custody. It was proved that the money in question had not been deposited in the bank, and the magistrates then remanded the prisoners for a week.

On December 12th, the prisoners were brought up on remand, when prosecutor informed the court that he had received £10 from the lad's father, and he did not wish the matter to be carried further. The magistrates reminded Mr. Boe that the compounding of a felony constituted an offence against the law, and that the case must proceed. Marlee was then committed for two months, with hard labour, and the woman, who has been cohabiting with the other prisoner, was discharged.—*Newcastle Daily Chronicle.*

Review.

Useful Chemical Tables, arranged for the use of Teachers and Students. By Adolphus Collenette, Professor of Chemistry, Elizabeth College, Guernsey. (F. Clarke, publisher. Price 6*d.*)

Cynics say that laziness, and not necessity, is the mother of invention, but it is unfair so to designate the sincere endeavours of an intelligent mind to smooth and make straight the paths of science. Mr. Collenette, in compiling these tables, has certainly taken a step in the right direction. They will become more useful to pharmacists than the author is aware of, he, apparently, only recommending them to teachers. How many pharmacists there are, men of this generation, who may have passed with honours five or six years ago, and are yet quite at sea with the new notation! It is here so simplified that the veriest tyro in chemistry may see the whole thing at a glance. The oxides, sulphides and chlorides of the sixty-three elements are all tabulated and the number and manner of their respective unions visible at once. To damn with faint praise is perhaps as bad as unqualified laudation, so before the compiler proceeds further (and we hope he may), his attention must be called to one or two points.

What necessity exists for establishing such a marked difference between metals and metalloids? a word generally objected to by physicists of the day, and not without reason, its meaning being contrary to its application. Even should, however, the compiler view H, etc. as the gaseous state of hydrogenium, etc., the objection grows stronger; the so-called metalloids becoming metals. The incorrect succession of the molecular arrangement of the combining elements would be likely to mislead a student, had not the author given his reasons for deviating from that course, which are, perhaps, advantageous from a professorial point of view, but seem odd from a purely scientific stand-point. A few apparent discrepancies are accounted for by the author, by having followed Dr. Frankland's plan, "whose hypothesis of absolute, latent and active atomicity gives a clear and reasonable explanation of the poly-atomicity of some elements."

The tables will prove of immense value to practical chemists, giving at a glance the various combinations of the elements with O, Cl and S. The blank forms attached can easily be filled-in for iodides, bromides, hydrates, acids, etc.; and it is to be hoped that the compiler will enlarge upon the idea, and give us a few more of these "useful tables."

Obituary.

BERTHOLD SEEMANN, Ph.D., M.A., V.P.A.S.L., F.L.S., F.R.G.S., etc.

It is our sad duty to chronicle the death of Dr. Seemann, the well-known botanist and traveller. He was born at Hanover, February 28th, 1825, and was educated at the Lyceum of his native town; Dr. Grotefend, a celebrated scholar, being at that time head master.

Dr. Seemann published his first article when only seventeen years of age; but his botanical career may be said to have commenced from 1846, when he was appointed naturalist to H.M.S. Herald, then on a surveying expedition in the Pacific. He left England in August, 1846; but on his arrival at Panama the 'Herald' and 'Pandora' had not returned from Vancouver's Island, and he profited by the delay to explore the greater part of the Isthmus. His observations were extended to every branch of science. On the return of the 'Herald' to Panama he joined, and remained with her until the completion of her voyage.

He also took the opportunity of making himself acquainted with the Pacific coast of South and Central America by frequent journeys inland, traversing Peru and Ecuador, and crossing the Cordillera of the Andes to Loja, one of the Cinchona regions. In his journey through part of Mexico he narrowly escaped with his life from the Comanche and Alpache Indians. In 1848, the 'Herald,' in company with other vessels, made three attempts to reach the Arctic regions to search for Sir John Franklin. In 1850 the 'Herald' began her homeward voyage, staying for some time at Hongkong, Singapore, etc., and reached England in 1851. The narrative of this voyage Dr. Seemann, at the request of the Admiralty, published in 2 vols. 8vo, under the title of

'Narrative of the Voyage of H.M.S. Herald, being a Circumnavigation of the Globe and Three Cruises to the Arctic Regions in Search of Sir John Franklin.' The animals collected during the voyage were described by the late Sir John Richardson, and the plants by Dr. Seemann himself. So highly was this work of Dr. Seemann's esteemed on the Continent, that the Imperial German Academy of Naturalists elected him a member and subsequently President-Adjunct for life.

In 1859 the sovereignty of Viti or Fiji Islands was formally offered to Great Britain, but before accepting it the Government commissioned Colonel Smythe and Dr. Seemann to examine and report on the islands. During a stay of eight months Dr. Seemann thoroughly examined the group, and published the results under the title of 'Viti; an Account of a Government Mission to the Vitian or Fijian Islands.' He also collected materials for the 'Flora Vitiensis,' a quarto work illustrated with plates, which he published at his own cost and risk. This work, the last sheets of which are now in the press, comprises not only the results of his own explorations, but also of all his predecessors, and contains valuable notes on the medical and economic uses of the plants. On this work and the 'Botany of H.M.S. Herald' Dr. Seemann's fame will rest.

In 1853, Dr. Seemann started the largest botanical journal ever attempted, under the title of 'Bonplandia,' taken from his academic name, to which the leading botanists of the world contributed. At the completion of the tenth volume, in consequence of Sir W. Hooker discontinuing the 'Kew Journal of Botany,' Dr. Seemann brought out his 'Bonplandia' in a new form, under the title of the 'Journal of Botany, British and Foreign,' which is still in existence. Besides numerous articles from his pen, literary, scientific and political, Dr. Seemann wrote 'A Popular History of Palms,' which is undoubtedly the best handbook we have on the subject.

From 1864 to his death Dr. Seemann's great practical experience and knowledge have been employed in examining and reporting on the resources and capabilities of portions of Nicaragua. A few months ago he left England to return to Nicaragua for a short time, as the managing director of a mining company; but on the 10th of October, shortly after his arrival at the Javali Mine, he died of a fever caught at Colon.

Dr. Seemann was a writer of some power in several languages. He always took a great interest in the Pharmaceutical Society. Some of his earlier articles on medical and economic plants will be found in the eleventh and twelfth volumes of the first series of this Journal. He never lost an opportunity of identifying a plant with its product, or clearing up any doubts, and throughout all his publications will be found valuable notes on this subject. He paid great attention to the Sarsaparillas, and up to his last journey was endeavouring to trace the origin of some of them. To botanical students he was ever ready to lend a helping hand, and many will deplore his death as that of a personal friend. In him science has lost a good botanist and an experienced and successful traveller.

MEETINGS FOR THE ENSUING WEEK.

THURSDAY, Dec. 28. ......*Royal Institution*, at 3 P.M.—"Ice, Air, Vapour and Water." By Professor Tyndall. (First Juvenile Lecture.)

London Institution, at 4 P.M.—"The Philosophy of Magic." (Second Holiday Lecture.)

SATURDAY, Dec. 30. ......*Royal Institution*, at 3 P.M.—Professor Tyndall's Second Juvenile Lecture.

BOOK RECEIVED.

MEMORANDA ON POISONS. By the late THOMAS HAWKES TANNER, M.D., F.L.S. Third edition. London: H. Renshaw. 1872.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

AN APPEAL FOR HELP.

Sir,—As the issue of your Journal for the 23rd of December will probably receive more of the attention of our members than usual, owing to the occurrence of Christmas, may I crave space for a piteous appeal which comes from a distressed widow of one of our body, whose case is so exceptionally hard, that neither can she be relieved from the funds of the Society nor yet from the Benevolent Fund,—her husband never having been a member of the Society, and having died before the registry of chemists and druggists was an accomplished fact? The facts are as follow:—

T. P., a chemist and druggist, was incapable, through lingering illness, of effecting registration under the provisions of the Pharmacy Act, which it will be remembered passed on the 31st July, 1868, and came into force immediately. In October of the same year, or less than three months, T. P., who never rallied, died, and his widow, being ineligible for registration, was compelled to dispose of the business at an enormous sacrifice, and deprive herself of her only means of support.

It will thus be seen the poor widow's distress arises from, and as a consequence of, the Pharmacy Act passing into law at the moment her husband lay dying, precluding her from continuing the business as she might otherwise have done, leaving her, without any fault of her own, adrift, with an invalid brother dependent upon her, without income or settled home, but with a shattered constitution and broken health.

The facts as narrated above can be avouched by myself and are well known to our Secretary, Mr. Bremridge. I would urge the case on the consideration of our brethren, in the hope that the knowledge of it will add greatly to the pleasurable enjoyment of the festive season approaching, by the satisfaction of knowing that many have contributed of their abundance to the relief of the pinching necessities of the widow of a deceased *confrère*, upon whom has fallen heavily the consequence of a reform, by which their social status has been greatly enhanced.

Mr. Bremridge has kindly consented to take charge of any donations; and, trusting that this appeal will be liberally responded to, as it deserves, I commend it to the sympathies of all.

H. SUGDEN EVANS.

THE ESTIMATION OF MORPHIA IN OPIUM.

Sir,—In the discussion upon my paper, on "The Estimation of Morphia in Opium," several gentlemen made remarks to which I wish briefly to reply.

Mr. Williams thought the solution of iodic acid should be more accurately standardized. There is, however, no necessity for this. A process for preparing the solution was given simply because the acid is not a common one, and might not happen to be at hand. Professor Redwood said that, although the iodine was removed from contact with the organic matter in half a minute, "still there was a race between two reactions," etc. This theoretical objection is, I imagine, more formidable in appearance than reality. There are, I should say, good grounds for believing that, under the conditions laid down, the secondary action is nipped in the bud, and that the results obtained are close approximations to the truth.

Professor Redwood informed the meeting that he "had made a great number of determinations of the quantity of morphia in opium by the several known processes," and "had arrived at the conclusion that the process given in the Pharmacopœia was the best." But this statement, though important, leaves untouched the question of the degree of accuracy of that process. My own trials of it have certainly not given me a favourable idea of its accuracy; indeed, the effect of washing the precipitates with chloroform was sufficient to dispel such a notion. Then, again, the comparison, under like conditions, of the reducing power of the washed precipitate and of pure morphia proved beyond doubt that the precipitate contained some substance besides morphia; and the only question open to dispute is whether the process fairly indicated its amount.

[The reduction process furnishes a ready means for assaying precipitates of morphia obtained by the usual methods. These precipitates should always be washed with chloroform, and their solutions shaken with carbon disulphide before being submitted to the test.]

Mr. Groves said "he should be surprised if such a complicated process could be got through in two hours and a half." I can assure him, however, that the work is quite easy of execution, and may be completed (not, of course, including the drying) in the time mentioned.

It appears Dr. Tilden would question the accuracy of any volumetric process for morphia until the reactions of the "twenty-five different alkaloids described as having been derived from opium" have been ascertained. From this point of view the prospect is dismal enough, and the case for the present, at all events, quite hopeless.

After all, let me repeat that I do not put forward my method as being accurate in the strict scientific sense, but as affording "nearer approximations to the truth" than are obtainable by the inexact processes in common use. This notion may be erroneous, but if so the proof will consist, not of opinions, but of facts.

Sheffield, December, 1871. JOHN T. MILLER.

Professor Tyndall's Theory of the Blue Colour of the Sky.

Sir,—Utterly unwarranted by any connection whatever, except from the fact of being a subscriber to your valuable periodical, I take the liberty of addressing you on a subject which has for me peculiar attractions.

In the eleventh Conversazione of the Liverpool Chemical Association, held February 3rd (PHARM. JOURN., February 18th, 1871, p. 671), Mr. Albert H. Samuel states, "The long red waves have also a much greater amplitude or depth than the short blue waves, and are thereby enabled to roll over or pass by small obstacles which would interrupt and throw back the short and shallow blue waves," . . . and "the long deep red waves roll over or pass by these small particles, but the short shallow blue waves are stopped by them and thrown back or scattered into space, to which they communicate the blue appearance which we call sky."

1. I desire to ask if, on spectral analysis, any sunbeam has yet been found without the blue ray?

2. If the blue rays or waves are stopped and the red ones come on to the retina, how is it that a red wave produces a blue impression?

3. If the blue is always present in all solar rays, what reason is there for saying that it is stopped in ethereal space?

4. I have always read that on the highest mountains and in balloons the sky has an inky hue. Has any one ever analysed sunbeams at such altitudes, and, if so, is the blue there more intense than at the ocean level?

5. Upon what basis rests the supposition that our atmosphere is "filled with countless millions of excessively minute particles"? Has Professor Tyndall ever had opportunity to experiment with the air of the highest altitudes accessible to man?

I can understand Professor Tyndall's theory of the sea in regard to its colour, but it appears to me that this is inapplicable to the explanation of the blue colour of the sky; for in the case of the sea we are above it, and of all the rays the blue is the last to be absorbed, and, for that reason, the sea is blue; but in the case of the air or sky we are inside, looking up through the sea of ether. Professor Tyndall says, "That when a beam of light entered the sea, the heat-rays were absorbed by the surface, the red rays by a very superficial layer of water, the green rays next, and ultimately the blue;" because of this, the air, to the eyes of a fish, would have various colours, according to the depth, and finally it would be blue, because this is the ultimate ray which advances beyond its associates—the rest were stopped. Apply this theoretical explanation to the air or sky, it should be red. And, finally, how is it that the short vibrations of the blue waves have so much more locomotive power in water than in air? To me this appears a bad rule that will not work both ways.

"On bringing the powerful light of a magnesium light to bear upon the particles, the water assumes the characteristic appearance of the sky" (*vide id.*). This appears to sustain the theory of the colour of the sea, and disprove that of the air or sky. On the supposition that the bottle was between the light and the retina, the blue ray reached it because the others could not get through the bottle—were stopped. According to the ethereal theory, the blue stopped in the bottle and the other rays went on; therefore, with the light in this position, the colour of the bottle would be a compound of the prismatic colours minus the blue. The sky is, with regard to our retina, in the same position as the contents of the bottle, *ergo*, the sky ought to be of the same colour.

How is it that this ethereal theory can be applied to what Thomson says?—

> "'Tis distance that lends enchantment to the view,
> And robes the distant mountain in its azure hue."

If you should have time to give me a word in your Journal, I will be much obliged. I am in this benighted land without light, except as it comes through the magnesium light of your periodical and others which I receive. I am so deep in the sea of ignorance here, that everything is blue to me, except when your red light comes from across the sea.

Trusting that you will make due allowance for this letter, I remain,

GEORGE S. BARNSLEY, M.D.

Barra Mansa, Province of Rio de Janeiro, Brazil, S. A., 8th September, 1871.

The Substitution of Proportional for Specified Weights and Measures.

Sir,—Whilst reading the very able paper by Dr. Redwood in the last Journal, it struck me that all the difficulty which the writer appeared to encounter, would be easily removed by the adoption of a new unit of weight (the decem of 10 grains), and another unit of measure (the septigallon, of 10,000 grains), and strike out all other denominations of weights or measures, so far as the Pharmacopœia is concerned. The advantages that I see in this are that we still keep the grain weight, which I hold it is not advisable to do away with at present, and we get a system of weights and measures strictly decimal, and the numbers can be read as proportional parts, or as grams in the metrical system, or by the system of decems in English grains. The terms are all quite convertible, and equivalent one to another. I think every formula could easily be expressed in decimal proportions, with only slight alterations, on this principle, and it would be a virtual adoption of the metrical system. My engagements will not permit me going into the subject at any length, but I have thought it worth while to point this out for the consideration of those who are interested in the subject.

Bradford, Dec. 12th, 1871. F. M. RIMMINGTON.

Shall the Pharmaceutical Society Cease to be an Educating Body?

Sir,—I perceive from Mr. Hustwick's letter that my meaning in an important portion of my communication of Nov. 18th is capable of being misunderstood. I think if that gentleman will do me the favour to read the passage once more, he will see he has somewhat misrepresented me. The fault, however, is doubtless my own. I ought to have made my meaning so clear as to be incapable of misapprehension, and I hasten to supply the defect.

My scheme pretends to suggest no change whatever in that portion of the Society's duties which concerns the Pass Examinations. It is only its educational processes that I presume to discuss; and the Annual Simultaneous Examination, with its attendant rewards, is suggested simply as a just and equitable method by which the Society could aid all systematic efforts, whether provincial or metropolitan, in the cause of scientific pharmaceutical education.

Clifton, December 16th, 1871. G. F. SCHACHT.

Difficulties in Dispensing.

Sir,—I again trouble you with a few lines, since the remarks of Mr. Wilkinson in the Journal of to-day seem to give me a sufficient reason for doing so.

In his first paragraph, Mr. W. alludes to a remark of mine in the Journal of the 25th, upon the bad tendency of part of his otherwise admirable paper read at Manchester a few weeks ago. Not having used the words without some thought, I state the reasons I had for my belief. They are these two. Firstly, Mr. W. did not throughout the whole course of his paper assert the principle that in all cases, when possible, the prescriber should be communicated with before any material liberty be taken with his prescription. Since then that gentleman has owned to agreement of opinion with me in this respect. Secondly, Mr. W., because unable himself to make a passable-looking pill, using the full quantity of ol. cinnam., quietly omits the half of the last-named ingredient, and asserts his method to be the only way of forming a decent pill.

Now, if a man of Mr. Wilkinson's attainments and experience meets with difficulties occasionally, can he not see that apprentices and assistants will often have pills to make which, while presenting no difficulties to him, may be fraught with great obstacles to them, when of course they may conclude they have an equal right with Mr. W. to omit ingredients difficult of manipulation? I would close this part of the subject by reminding your readers that J. B. has given us a method by which the whole quantity of ol. cinnam. may be contained by the iron and gentian pills without the addition or subtraction of any active ingredient.

In the next part of the letter alluded to it is asked, Are not the extracts likely to be damaged by drying them? Perhaps so; but then Mr. W. must remember that he himself recommends this course in regard to ext. rhei in his own paper.

In reply to the next paragraph, which asks what real difference there is in the omission of half a quantity of essential oil ordered and the wasting of the same quantity upon the slab, I answer, but little; but would still recommend that we endeavour so to prepare the pills that they shall contain the whole.

And now, in regard to the more personal part of the epistle, I must first ask the writer to very carefully note that my presumption concerning the Manchester chemists was contingent upon the fact that in the Journal no report of the expression of any opposite opinion about the propriety of thus dealing with prescriptions was given, although part of the debate was reported; but as such objections were made at the Manchester meeting against the lecturer's views, he will see that I have not in reality the smallest charge to bring against the Manchester chemists as a body.

Finally, I am sorry to have to confess that I fail to see the applicability of the fable to which my friend so nicely alludes. Allowing, for the sake of argument, that my supposed attack upon the Manchester chemists is similar to that of the baser quadrupeds upon the lion, yet I can hardly see that this great body of talented and intelligent men are to be compared with the aged, dying forest king, incapable of self-defence.

To conclude, I cordially sympathize with Mr. Wilkinson, the more especially as I find that when he prepared the paper he had no thought of seeing it in print; and I know that it is far easier to find fault with a paper written by another than to read half so good an one myself.

WALTER B. CLARK.

Leicester, Dec. 16th, 1871.

Sir,—In reply to Mr. Wilkinson, I beg to say I do not possibly see that any injury can result to the extract (as he intimates), provided the suggestion in my former letter is closely adhered to, it being, strictly speaking, nothing more than what is directed in the Pharmacopœia. I can understand that if the heat applied be so great as to burn the extract, its active properties would no doubt be impaired.

I am sorry at having mistaken Mr. W.'s question in reference to the second prescription given in his letter of the 20th ult., but the correspondence had hitherto been on the manipulation, not directions, therefore I naturally concluded that when Mr. W. asked the question he referred to the manipulation, as he did not specially state otherwise.

Every one is well aware that occasionally cases do occur in which the dispenser is bound to exercise a little common sense, still I would not uphold the principle of making material alterations without first communicating with the prescriber, unless I was sure he had committed some palpable error, and could not be easily consulted.

Hackney, Dec. 18th, 1871. F. W. S.

Sir,—Mr. Wilkinson appears to have written his reply to the numerous criticisms his paper called forth whilst smarting under their aspersions, but with these I have nothing to do.

I merely suggested a plan by which the prescription he quoted could be formed into good and firm pills containing the whole of the oil of cinnamon ordered. As my using the tragacanth and magnesia was the result of several trials, I most certainly do not understand Mr. Wilkinson terming it a "pet scheme."

It is very necessary to be able to dispense pills containing an excessive quantity of essential oil, and as the subject is decidedly worth ventilating, I should like to have other opinions or further suggestions from those who have them to offer. Omitting part of the oil or squeezing it out afterwards are neither of them desirable processes.

The pills I made at time of writing to you before still keep their shape, and are in good condition.

17, *Bull Street, Birmingham,* JAMES SPENCER.
December 19th, 1871.

Shall the Pharmaceutical Society cease to be an Educating Body?—We have received a lengthy communication from a member of the Society, in reference to Mr. Schacht's paper on the educational question. The chief point of our correspondent's letter refers to what he regards as a change in the constitution of the Society which has found eloquent supporters, namely, the proposal to conduct all the Examinations by written questions,—these to be forwarded to the provinces, and answered in accordance with known stringent regulations. Our correspondent thinks that the Preliminary is the only one where this course is available. He objects that the dispensing department of the examination cannot be trailed round to various provincial centres, and that materia medica, deprived of its illustrative specimens, or botany minus living plants, would be a farce; while book chemistry alone is not worth a straw. Such a mode of procedure, in our correspondent's opinion, would merely result in producing patent paper pharmacists, and he says that he, being engaged in London business and having a wife and family to support, could not afford to engage such an one for his assistant.

P. Sparrow.—We are unable to furnish the recipe asked for.

S. T.—We would recommend you to address the question to Professor Crace-Calvert.

"*Puzzled.*"—The most simple way would be to try the experiments.

"*A Student.*"—As your difficulty appears to arise from what you deem to be an error or an obscurity in the book referred to, the best way would be to communicate with the author; but before doing so, it would be well to attempt yourself to solve the query. Probably a little more care would enable you to do this, for you have forwarded to us an equation in which carbonate of zinc does not occur.

W. J. Smith.—The statement is quite correct; it is "precipitated black."

A. B. C.—We presume that a calendar month would be meant, the engagement being a yearly one.

W. Bates.—Yes.

J. Bradshaw.—If the quinine is dissolved in the tinct. ferri perchlor., the water added, and, lastly, the syrup, the mixture will present an uniform appearance. The tincture should be that of the B. P.

"*Oxygen.*"—(1.) Of the two books mentioned, Royle's 'Materia Medica' would best answer your purpose. There is also a new edition of 'Pereira' announced. (2.) Roscoe's 'Chemistry.'

C. Gerring.—In most works on chemistry or materia medica.

A. M'Lean.—Your paper has been received and is under consideration.

W. M. B.—Yes; but the proprietor is responsible.

"*A Country Chemist.*"—Inquiry has been made, and the answer shall be published when received.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Knowles, Mr. B. M. Johnson, Mr. G. F. Schacht, Mr. J. Ince, Mr. T. Bradley, Mr. W. B. Clarke, Mr. F. J. Hayes, Mr. Spencer, Mr. Sandy, Mr. R. G. Mumbray, Mr. J. Knowles, M. P. S., X. Y. Z., "Student of the Pharmaceutical Society."

THE APPLICATION OF MOLECULAR ROTATION TO THE DETERMINATION OF THE VALUE OF CINCHONA BARKS.

BY DR. J. E. DE VRIJ.

Since the publication of my first paper on this subject in the PHARMACEUTICAL JOURNAL of July 1st, the German Chemical Society at Berlin received on the 19th of the *same* month a paper from Mr. O. Hesse* (of Stuttgardt), containing a condemnatory criticism of my paper. Since the labours of this chemist in the field of quinology are highly esteemed by me, I am happy that my paper so soon attracted his attention, though I regret that he could not spare some more time to apply my process practically to some of the many barks which come into his hands. If he had done so, I am sure that his criticism would have been less condemnatory, and that he would probably have agreed with me that my process, notwithstanding all the imperfections which I have myself indicated in my paper, is a very valuable auxiliary in the investigation of cinchona barks. But, however this may be, I have since continued my investigations in the same direction, and have thus been led to amend my process.

In my former paper I recommended two observations to be made:—

1. The molecular rotation of all the alkaloids.
2. The molecular rotation of the part insoluble in ether.

I have since found it necessary to add a third observation, viz. to determine the molecular rotation of the part soluble in ether. The publication of my experiments in this direction will prove that of all the three observations, the last is the most interesting for the manufacturer of quinine:—

C. Calisaya hybrida from Java (*C. Hassk.*, Miq.)†

Mixed alkaloids . . .	[α]j = 50°·2 ↶.
Part insoluble in ether .	[α]j = 102°·7 ↷.
Part soluble in ether . .	[α]j = 97° ↶.

C. officinalis from Ceylon.‡

Mixed alkaloids . . .	[α]j = 145° ↶.
Part soluble in ether . .	[α]j = 162° ↶.

Rough mixed alkaloids from *C. succirubra.*

Darjeeling, prepared by Dr. B. Simpson. Received by me 24th August, 1871.

Mixed alkaloids . . .	[α]j = 24° ↷.
Part soluble in ether . .	[α]j = 81°·17 ↶.

The mixed alkaloids proved to contain all the five alkaloids.

C. succirubra from Ootacamund.

Bark sold in London, August, 1867.

Mixed alkaloids . . .	[α]j = 12°·8 ↶.
Part insoluble in ether .	[α]j = 29°·3 ↷.
Part soluble in ether . .	[α]j = 51°·4 ↶.

The mixed alkaloids proved to contain four alkaloids and no quinidine.

C. Calisaya from Java.

Bark from a stem preserved in the Colonial Museum at Haarlem.

Total amount of alkaloids 3·7 per cent.	[α]j=115° ↷.
Part soluble in ether	[α]j=113° ↷.

The alkaloids consisted of quinidine, cinchonine, cinchonidine and amorphous alkaloids, whilst not a trace of quinine could be found.

I will not occupy the space of this Journal by discussing these results, but will only quote one fact to prove their importance.

In April, 1870, the first Java bark was sold at Amsterdam. According to the official report to the Government from one of our eminent professors of chemistry, the Java *Calisaya* bark proved to be of first-rate quality, and not inferior to the American *Calisaya.** This judgment was founded upon the fact, that he obtained from that bark 3·5 per cent. of alkaloid soluble in ether, which he considered to be quinine. My investigation, however, of this bark proved that the part of the alkaloids soluble in ether turned the plane of polarization strongly to the right, whilst analysis proved that this bark contained only a trace of quinine, but a large amount of amorphous alkaloid soluble in ether.

In my former paper, I stated that the deviation produced by quinine is different, according as it is observed in solution in alcohol or in diluted acid; and that I thought it very probable that this difference would exist in the same direction with the other alkaloids. This supposition has been confirmed since, by the observations made by me with the valuable co-operation of the distinguished Professor of Chemistry to the Polytechnic School at Delft, Dr. A. C. Oudemans. We are still occupied in determining the molecular rotation of all the cinchona alkaloids both in alcoholic and acid solutions, the results of which observations I intend to publish in this periodical as soon as they are completed.

VESICATING INSECTS.

BY M. C. COOKE, M.A.

(*Continued from page* 504.)

MARGINED BLISTER-FLY, *Lytta marginata*, Latr.; black, with the margins of the elytra ash-coloured.—Oliv. Ent. t. 1. f. 2; Durand, Journ. Phil. Col. of Pharm. ii. p. 274. f. 6; Wood and Bache, Disp. U. S. (1867) p. 206; Harris, Injurious Insects (1862), p. 137. f. 62; Packard's Guide, f. 454. *Lytta marginata*, Fabr. S. E. p. 260; Brandt and Ratzb. ii. t. xviii. f. 11. *Meloe cinereus*, Forst. Nov. Sp. i. p. 62. *Epicauta cinerea*, Leconte, Cat. Col. U. S.

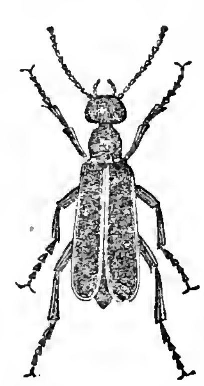

Fig. 10.—*Lytta marginata.*

Inhabits North America and (according to Fabricius) the Cape of Good Hope.

This is somewhat larger than *C. vittata* and of a different shape. The elytra are black, with the suture and margin ash-coloured. The head, thorax and abdomen are black, but nearly covered with an ash-coloured down; and on the upper part of the abdomen, under the wings, are two longitudinal lines of a bright clay colour. The insect is usually found in the latter part of summer, upon different species of *Clematis*, and frequents especially the lower branches which trail along the ground. Professor Woodhouse, of Philadelphia, first ascertained its vesicating properties; but it had previously been described by Fabricius as a native of the Cape of Good Hope. Dr. Harris, of Massachusetts, found it equally efficient as a vesicatory with any other species of the genus. The following is Harris's graphic description of this insect:—

"There is a large blistering-beetle which is very common on the virgin's-bower (*Clematis virginiana*) a trailing plant, which grows wild in the fields and is cultivated for covering arbours. I have sometimes seen this plant completely stripped of its leaves by these insects during the month of August. They are very shy, and when disturbed fall immediately from the leaves and attempt to conceal themselves among the grass. They most commonly resort to the low branches of the clematis, or those that trail upon the ground, and more rarely attack the upper parts of the vine. They also eat the leaves of various kinds of *Ranunculus* or buttercups, and, in the Middle and Southern States, those of *Clematis viorna* and *crispa*. This beetle is the *Cantharis marginata* of Olivier, or margined *Cantharis*. It measures $\frac{6}{10}$ or $\frac{7}{10}$ of an inch in length. Its head and thorax are thickly covered with short grey down, and have a black spot on the upper side of each; the wing-covers are black, with a very narrow grey edging; and the under side of the body and legs are also grey."

This is one of the species commonly employed in the United States of America, and is enumerated as such in Wood and Bache's 'Dispensatory.'

ASH-COLOURED BLISTER-FLY, *Lytta cinerea*, Fabr. —Fabr. Syst. ii. p. 80; Brandt and Ratzb. ii. t. xviii. f. 13; Pall. Ic. p. 98. t. E. f. 30; Leconte, Syn. p. 339. *Lytta Fabricii*, Lec.; Durand, Journ. Phil. Coll. Pharm. ii. 274. f. 5; Wood and Bache, U.S. Disp. (1867), p. 206; Harris, Injurious Insects, etc. (1862), p. 138. f. 63; Packard's Guide, p. 480. f. 453 *a*.

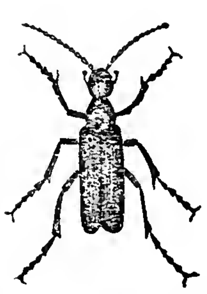

Fig. 11.—*Lytta cinerea.*

Found in the Northern and Middle States of North America.

The ash-coloured *Cantharis* closely resembles the potato-fly in figure and size, but differs from it in colour. The elytra and body are black, without the yellow stripes that characterize *C. vittata*, and are entirely covered with a short and dense ash-coloured down, which conceals the proper colours of the insect. The feelers are black, and the first and second joints are very large in the male. This species also inhabits the potato plants, and is occasionally found on other plants, as the English bean and wild indigo. It is a native of the Northern and Middle States. Illiger in 1801 discovered its vesicating properties, but Dr. Gorham was the first to call public attention particularly to the subject, in a communication addressed, in the year 1808, to the Medical Society of Massachusetts.

The most destructive kind of *Cantharis* found in Massachusetts is of a more slender form than *C. marginata*, and measures only $\frac{11}{20}$ to ^{6} of an inch in length. Its antennæ and feet are black, and all the rest of the body is ashen-grey, being thickly covered with a very short down of that colour. Hence it is called *C. cinerea*, or the ash-coloured *Cantharis*. When the insect is rubbed, the ash-coloured substance comes off, leaving the surface black. It begins to appear in gardens about the 20th of June, and is very fond of the leaves of the English bean, which it sometimes entirely destroys. It is also occasionally found in considerable numbers on potato vines; and in Cambridge, Massachusetts, it has repeatedly appeared in great profusion upon hedges of the honey-locust, which have been entirely stripped of foliage by these voracious insects. They are also found on the wild indigo-weed.

In the night, and in rainy weather, they descend from the plants, and burrow in the ground or under leaves and tufts of grass. Thither also they retire for shelter during the heat of the day, being most actively engaged in eating in the morning and evening. About the 1st of August they go into the ground and lay their eggs, and these are hatched in the course of one month. The larvæ are slender, somewhat flattened grubs, of a yellowish colour, banded with black, with a small reddish head and six legs. These grubs are very active in their motions, and appear to live upon fine roots in the ground; but I have not been able to keep them till they arrived at maturity, and therefore know nothing further of their history (Harris).

(*To be continued.*)

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

POTASSÆ CARBONAS.—[§ K_2CO_3 with about 16 per cent. of water of crystallization.

Obtained from commercial pearlash, the product of the lixiviation of wood-ashes, by treating the pearlash with its own weight of distilled water, and evaporating the solution so formed to dryness, while it is kept briskly agitated.]

Wood-ashes still supply us with all the carbonate of potassium required in so many great manufactures, notwithstanding that more than one attempt has been made to procure that salt from other and especially mineral sources.

Of course, carbonate of potassium does not exist in the tissues of the plants from which it is obtained, but is the result of incinerating the various organic salts present therein. These salts (tartrates, citrates, malates, oxalates, etc.) contain at least one atom of carbon to every atom of potassium, and by burning them in the air they leave a residue of carbonate. It was, in fact, called salt of tartar, from having been formerly prepared from the cream of tartar, or acid tartrate of potassium. Wood-ash contains varying proportions of other salts, such as the sulphate and chloride of potassium, as well as silica. These are for the greater part got rid of in the process of lixiviation, shortly described in the Pharmacopœia.

Carbonate of potassium is recognizable by its deliquescence, by effervescing with acids, and by forming with hydrochloric acid a solution which with perchloride of platinum gives a yellow precipitate of the double chloride, $PtCl_4 . 2 KCl$. It always contains traces of silica, sulphate and chloride. A very pure carbonate can be readily made if required by heating crystals of the bicarbonate to dull redness.

[§ Test. 8·3 grams require for neutralization at least 98 cubic centimetres of the volumetric solution of oxalic acid.] This shows the presence of 81·4 per cent. of K_2CO_3. For since 100 c. c. are required to neutralize 6·9 gram of carbonate of potassium, or $\frac{1}{20}$ of a gram-molecule, 98 c. c. indicate 6·762 gram, and this quantity in 8·3 grams is 81·4 per cent.

POTASSÆ CHLORAS, $KClO_3$.—Formerly chlorate of potassium was prepared by passing chlorine gas into a hot solution of the carbonate or hydrate of potassium. The nature of the reaction will be further discussed under bromide and iodide of potassium; it is as follows:—

$$6KHO + 3Cl_2 = 5KCl + KClO_3 + H_2O.$$

But inasmuch as five-sixths of the potash is thus rendered comparatively valueless by being transformed into chloride, the happy idea of substituting an equivalent quantity of lime was adopted.

According to the Pharmacopœia, carbonate of potassium and slaked lime are mixed together, damped with water and saturated with chlorine by passing the gas into the mixture. The mass usually assumes a pinkish colour from the conversion into permanganate of a minute quantity of manganese, mechanically carried over into it with the chlorine. It is boiled with water, filtered from the insoluble carbonate of calcium, and evaporated to the crystallizing-point. The mother liquors, after the deposition of the chlorate of potassium, retain chloride of calcium. The reactions by which these three salts are formed, consist probably in the formation of chlorinated lime in the first instance, and the transformation of this compound by boiling with the alkaline carbonate into the soluble chlorate and chloride and the insoluble carbonate.

$$1.)\ \underset{\text{Lime.}}{CaO} + \underset{\text{Chlorine.}}{Cl_2} = \underset{\text{Chlorinated Lime.}}{CaOCl_2} = CaCl(ClO).$$

$$2.)\ \underset{\text{Chlor. Lime.}}{6CaCl_2O} + \underset{\text{Carbonate of Potassium.}}{K_2CO_3} =$$

$$\underset{\text{Chloride of Calcium.}}{5CaCl_2} + \underset{\text{Carbonate of Calcium.}}{CaCO_3} + \underset{\text{Chlorate of Potassium.}}{2KClO_3}$$

Chlorate of potassium forms rhomboidal plates, soluble in about 16 times their weight of cold, and about $1\frac{1}{2}$ time their weight of boiling water.

[§ It explodes when triturated with sulphur. Its solution is not affected by nitrate of silver, nor oxalate of ammonia. By heat it fuses, giving off oxygen gas, and leaves a white residue (KCl), readily forming with water a neutral solution, which is precipitated white by nitrate of silver, and yellow by perchloride of platinum.] The action of a moderate heat is at first to produce a mixture of perchlorate and chloride.

$$2KClO_3 = KClO_4 + KCl + O_2.$$

A higher temperature expels the whole of the oxygen.

Sulphuric acid evolves from chlorate of potassium a yellow gas, chloric peroxide (Cl_2O_4), which explodes when gently heated.

Hydrochloric acid gives a yellow gas, formerly called *Euchlorine*, which is a mixture of chlorine with one of its oxides.

The following are the acids formed by chlorine in union with hydrogen and oxygen; they are all monobasic.

Acids.		Potassium Salts.	
Hydrochloric .	HCl	Chloride . .	KCl
Hypochlorous .	$HClO$	Hypochlorite .	$KClO$
Chlorous . .	$HClO_2$	Chlorite . .	$KClO_2$
Chloric . . .	$HClO_3$	Chlorate . .	$KClO_3$
Perchloric . .	$HClO_4$	Perchlorate .	$KClO_4$

POTASSÆ CITRAS.—Citric acid neutralized with carbonate of potassium, and the solution evaporated to dryness.

$$3K_2CO_3 + 2H_3C_6H_5O_7$$
$$= 3(H_2O \cdot CO_2) + 2K_3C_6H_5O_7.$$

[§ Its solution mixed with solution of chloride of calcium, remains clear till it is boiled, when a white precipitate separates readily soluble in acetic acid.] The non-precipitation in the cold distinguishes it from the tartrate.

THE CULTIVATION AND USE OF THE DANDELION IN INDIA.

BY JOHN R. JACKSON, A.L.S.,
Curator of Museums, Royal Gardens, Kew.

The dandelion is perhaps one of the most cosmopolitan of medicinal plants, for besides being an actually recognized article in pharmacy, it is also largely collected and used by the peasantry in rural districts in liver complaints and in cases of dyspepsia. *Taraxacum officinale*, Wiggers (*Leontodon Taraxacum*, L.), is very widely distributed through Europe, Central Asia, North America and the arctic regions. Several varieties of the plant are known in this country, some of which have been dignified into species. The commonest variety is that mostly found on cultivated ground and known as *Taraxacum Dens-leonis*, Desf., which has bright green runcinate-pinnatifid leaves and the bracts of the involucre recurved. The plant has great powers of reproduction, both by its roots and by the pappus seeds, which are easily wafted by the winds to distances, where they readily germinate and establish themselves.

The plants grow abundantly throughout the Himalayas, where two or more distinct varieties are known; one is described as having large double flowers, quite the size of a rupee, and another with small single flowers, rather larger than a sixpence. The larger-flowered form is said to possess medicinal properties in by far the greatest degree. The plants are likewise cultivated in various parts of India, and the roots are collected between the months of September and February. To cultivate the plants properly, the following plan is recommended:—The seeds should be sown in beds, and the young plants, when sufficiently grown, should be planted out on ridges at a distance of nine inches from each other. This system of planting is the best suited for the production of large roots, which is the principal end to be obtained, and, to further ensure this result, the flowers should be gathered as they open. The roots, after they are taken up, are washed clean and wiped dry.

Taraxacum roots are used in a variety of ways in India; one useful form is that of a paste, which is made by pounding the fresh roots, putting the mass into tins or jars and gently baking or heating in an oven; when cool, the paste is ready for use and can be kept for a long time. To prepare dandelion-coffee, the roots are washed, dried in the sun and cut up into small pieces, after which they are roasted in a similar manner to true coffee; they are then ground, and to every nine ounces of coffee one ounce of pounded dandelion-root may be added; these proportions make an excellent and useful beverage. The use of this coffee in India has been much recommended.

Lieutenant Pegson, in a communication to the Agri-horticultural Society of India, advocating the more general cultivation and use of the dandelion, says, "Medical men admit the value of this preparation, and I know several gentlemen in India who are, by their own admission, kept alive by the daily use of *Taraxacum*-coffee. It is fairly entitled to be called a specific for the cure of torpid liver, a complaint from which the majority of Europeans suffer; the fact being made known when they proceed to a cool or hill climate and shiver and shake with cold while the thermometer is at 62° F. only. The sallow complexion of such men, women and children, their languid movements and their enjoyment of heat, all alike proclaim that they are suffering from sluggish action of the liver. The conserve of *Taraxacum* may be made into syrup for use. Horses and valuable dogs, sheep and poultry, all suffer in India from disease of the liver. A bolus of *Taraxacum* conserve to a horse, and a pill thereof to a fowl, would be most beneficial and act as a curative agent. Rabbits also suffer greatly from liver disease, but if they were supplied with a few (two to four) green *Taraxacum* leaves twice or thrice a week, the mortality resulting from this (hitherto) incurable disease would disappear, and rabbits could then be extensively raised for the market."

CONTRIBUTIONS TO THE HISTORY OF THE OPIUM ALKALOIDS.*

BY C. R. A. WRIGHT, D.SC.

Lecturer on Chemistry in St. Mary's Hospital Medical School.

PART III.

(*Continued from page* 506.)

3. *Action of Sodium Carbonate on the Compound* $C_{68}H_{86}I_2N_4O_{12}4HI$.

On adding sodium carbonate to the scarcely warm aqueous solution of this compound a voluminous white precipitate is produced, which is apparently a mixture of three bases, two of which contain iodine, whilst the third is free from that ingredient. The first one, which forms only a small fraction of the whole, is the free base of the original compound, $C_{68}H_{86}I_2N_4O_{12}$; this is readily soluble in ether, and may be obtained as hydriodate (as previously stated) by digesting the precipitate with ether, and agitation of the extract with hydriodic acid, whereby the original substance is reproduced. To prevent frothing, the precipitate must be well drained from the aqueous portion. By continuing the extraction until some 6 litres of ether have been employed for exhausting the precipitate from 40 grms. of original substance, the whole of this base is removed, or nearly so. Attempts to prepare the base itself by evaporation of the ether yielded only a tarry substance which could not be removed from the vessel employed; treatment with water or alcohol more or less decomposes it.

* Read before the Royal Society, November 16, 1871.

By employing a large bulk of ether after this first base has been almost wholly removed, an extract is obtained from which on evaporation solid flakes separate; these are much less soluble in ether than the first base, and after drying at 100° gave the following numbers, indicating the formula $C_{68}H_{81}IN_4O_{10}$.

0·1985 grm. gave 0·4705 CO_2 and 0·119 H_2O.
0·1210 grm. gave 0·2600 AgI.

	Calculated.		Found.
C_{68}	816	65·81	64·65
H_{81}	81	6·53	6·66
I	127	10·24	11·61
N_4	56	4·52	
O_{10}	160	12·90	
$C_{68}H_{81}IN_4O_{10}$	1240	100·00	

Apparently these flakes still retained a trace of the first base; the mother-liquor from which they separated, when evaporated to dryness, left a small amount of residue containing 14·18 per cent. of iodine. Treated with hydriodic acid, these flakes gave a hydriodate yielding these numbers after drying at 100°:—

0·3675 grm. gave 0·6335 CO_2 and 0·181 H_2O.
0·371 grm. gave 0·2405 AgI.

	Calculated.		Found.
C_{68}	816	46·58	47·00
H_{85}	85	4·85	5·47
I_5	635	36·24	35·02
N_4	56	3·20	
O_{10}	160	9·13	
$C_{68}H_{81}IN_4O_{10}, 4HI$	1752	100·00	

Evidently a slight loss of iodine has occurred from the action of the adhering moisture while drying, as the original flakes contained rather too high a percentage of iodine. This base is formed from the original one by the reaction—

$$C_{68}H_{86}I_2N_4O_{12}, 4HI = 2H_2O + HI + C_{68}H_{81}IN_4O_{10}, 4HI,$$

identical with that taking place on treatment with water.

A portion of the substance left after extraction with ether was treated several times successively with large bulks of ether (about 4 litres of ether to 10 grms. of precipitate each extraction). After the majority of the substance had thus been dissolved, a portion of the last ether extracts was evaporated down and yielded flakes agreeing approximately with the composition required for a mixture of 1 molecule of $C_{68}H_{81}IN_4O_{10}$, and 2 molecules of $C_{68}H_{80}N_4O_{10}$.

0·3565 grm. gave 0·926 CO_2 and 0·237 H_2O.
0·376 grm. 0·255 AgI.
0·2455 grm. gave 0·170 AgI.

	Calculated.	Found.	
C	70·67	70·84	
H	6·96	7·39	
I	3·67	3·66	3·73

From the foregoing experiments it is clear that the action of sodium carbonate on the compound

$$C_{68}H_{86}I_2N_4O_{12}, 4HI$$

is identical with that of water described in (2), the two bases, $C_{68}H_{81}IN_4O_{10}$ and $C_{68}H_{80}N_4O_{10}$, being the principal products.

On precipitating in a similar way the compound

$$C_{68}H_{82}I_2N_4O_{10}, 4HI,$$

the same reaction appears to take place; from the precipitate ether extracts only traces at first, indicating probably that the base $C_{68}H_{82}I_2N_4O_{10}$ is not produced in any quantity; as apparently the more highly iodized bases are more soluble in ether.

On treating the compound $C_{68}H_{82}I_2N_4O_6, 4HI$ in the same way, an analogous reaction seems to ensue; the precipitate is very sparingly soluble in ether, and on treatment with hydriodic acid furnished a hydriodate of which 0·233 grm. dried at 100° gave 0·142 AgI; hence I=29·94 per cent.; the compound $C_{68}H_{88}N_2O_{10},4HI$ requires 31·13 per cent., whilst the original substance requires 40·53 per cent.

4. *Action of Hydriodic Acid on some of the foregoing substances.*

As the action of water on the three compounds first described is to remove the elements of HI associated with the carbon radicals of the bases, it was thought probable that by treating the products of the action of water on these compounds with strong boiling hydriodic acid, the HI thus lost might be again added on. A reaction of this nature does indeed take place, but does not always stop at the reproduction of the original bodies, another equivalent of HI being also added on; moreover, in some instances a number of molecules of H_2O are likewise taken up, and are not separated from the compounds ultimately formed even by some days' exposure to a temperature of 100°.

On treating the compound $C_{68}H_{80}N_4O_{10},4HI$ with about ten parts of 55 per cent. of hydriodic acid (a little piece of phosphorus being also added to prevent separation of iodine from the HI by the heat) and heating to boiling, a syrupy liquid is obtained, from which water precipitates (after filtration of phosphorus) a tar resembling in all its physical characters the compound $C_{68}H_{86}I_2N_4O_{12},4HI$; it contains, however, the elements of $HI+10H_2O$ more than this substance. The same substance apparently is generated by treating the intermediate compound

$$C_{68}H_{81}IN_4O_{12},4HI$$

with hydriodic acid in the same manner.

(A.) From the compound $C_{68}H_{80}N_4O_{10},4I$; dried at 100° till constant:—

0·3565 grm. gave 0·483 CO_2 and 0·158 H_2O.
0·3835 grm. gave 0·278 AgI.

(B.) (A) dried twelve hours more at 100°, had turned a much darker colour, probably indicating absorption of oxygen:—

0·329 grm. gave 0·434 CO_2 and 0·155 H_2O.
0·561 grm. gave 0·419 AgI.

(C.) From the compound $C_{68}H_{81}IN_4O_{10},4HI$:—
0·377 grm. gave 0·485 CO_2 and 0·175 H_2O.
0·387 grm. gave 0·2855 AgI.

	Calculated.		Found. A.	B.	C.	Mean.
C_{68}	816	36·69	36·95	35·98	35·09	36·01
H_{111}	111	4·98	4·93	5·24	5·16	5·11
I_7	889	39·98	39·16	40·35	39·87	39·79
N_4	56	2·52				
O_{22}	352	15·83				
	2224	100·00				

$C_{68}H_{107}I_3N_4O_{22},4HI$.

Hence this body is formed by the equations—

$$C_{68}H_{80}N_4O_{10},4HI+3HI+12H_2O= \\ =C_{68}H_{107}I_3N_4O_{22},4HI.$$

$$C_{68}H_{81}IN_4O_{10},4HI+2HI+12H_2O= \\ =C_{68}H_{107}I_3N_4O_{22},4HI.$$

On treating the compound $C_{68}H_{88}I_3N_4O_{10},4HI$ in the same way, a product is obtained only differing from the original substance by one equivalent of HI; dried at 100°:—

0·3995 grm. gave 0·6800 CO_2 and 0·197 H_2O.
0·3215 grm. gave 0·2200 AgI.

	Calculated.		Found.
C_{68}	816	46·36	46·41
H_{93}	93	5·28	5·48
I_5	635	36·09	36·97
N_4	56	3·18	
O_{10}	160	9·09	
$C_{68}H_{89}IN_4O_{10},4HI$	1760	100·00	

Hence this body appears to have been formed by the reaction $C_{68}H_{88}N_4O_{10},4HI+HI=C_{68}H_{89}IN_4O_{10},4HI$, no water having been taken up; whilst in the case of the other non-iodized base, 3 molecules of HI and 12 of H_2O are assimilated.

In order to see if the combined action of phosphorus and hydriodic acid would transform the compound

$$C_{68}H_{86}I_2N_4O_{12},4HI$$

into the body $C_{68}H_{82}I_2N_4O_6,4HI$, the former compound was dissolved in about 10 parts of 55 per cent. hydriodic acid, and boiled until most of the acid had volatilized; a considerable quantity of phosphoric acid was formed during the reaction, and on precipitating the compound produced with water, and drying at 100°, the following numbers were obtained:—

0·2795 grm. gave 0·3900 CO_2 and 0·136 H_2O.
0·4195 grm. gave 0·327 AgI.
0·4225 grm. gave 0·333 AgI.

	Calculated.		Found.	
C_{68}	816	38·42	38·06	
H_{107}	107	5·04	5·41	
I_7	889	41·85	42·12	42·59
N_4	56	2·64		
O_{16}	256	12·05		
$C_{68}H_{103}I_3N_4O_{16},4HI$	2124	100·00		

From these numbers it appears that the substance produced may be considered as formed by the reactions,

$$C_{68}H_{86}I_2N_4O_{12},4HI + 8HI= \\ =I_8 + 6H_2O + C_{68}H_{82}I_2N_4O_6,4HI.$$

$$C_{68}H_{82}I_2N_4O_6,4HI + HI + 10H_2O= \\ =C_{68}H_{103}I_3N_4O_{16},4HI.$$

It is not easy to explain why the reaction should stop short at the end of the first stage, when codeia is treated with hydriodic acid and boiled up to 130°; possibly the presence of a much larger quantity of phosphorus acids in this case may tend to present the second reaction ensuing.

5. *Discussion of the Foregoing Results.*

From the complex constitution of the substances described above, it is at present thought unadvisable to attempt to give names to them. All the bodies previously mentioned may be regarded as being derived from one or other of the two bases $C_{17}H_{21}NO_3$, and $C_{17}H_{21}NO_2$ by multiplication of the molecule, and addition or subtraction of the elements of water and of hydriodic acid.

These two (hypothetical) bases contain H_2 more than morphia and deoxymorphia respectively; denoting the first by the symbol X, and the second by Y, the following general formulæ will indicate all the compounds previously described:—

$$4X + mHI + nH_2O,$$
$$4Y + mHI + nH_2O.$$

Thus the following table illustrates the mutual relations of the compounds described:—

Source of Compound.	Formulæ.
(A) Codeia, HI, and P at 150°	$C_{68}H_{86}I_2N_4O_{12},4HI=4X+6HI$.
(B) Do. 110° to 115°	$C_{68}H_{82}I_2N_4O_{10},4HI=4H+6HI-2H_2O$.
(C) (A) treated with water or Na_2CO_3	$C_{68}H_{81}IN_4O_{10},4HI=4X+5HI-2H_2O$.
(D) Free base of (C). (A) treated with Na_2CO_3	$C_{68}H_{81}IN_4O_{10}=4X+HI-2H_2O$.

Source of Compound.	Formulæ.
(E) Further action of water on (C) . .	$C_{68}H_{80}N_4O_{10},4HI=4X+4HI-2H_2O$.
(F) Action of HI on (E)	$C_{68}H_{107}I_3N_4O_{22},4HI=4X+7HI+10H_2O$.
(G) Codeia, HI, and P at 135° . . .	$C_{68}H_{82}I_2N_4O_6,4HI=4Y+6HI-2H_2O$.
(H) Action of water on (G)	$C_{68}H_{88}N_4O_{10},4HI=4Y+4HI+2H_2O$.
(I) Action of HI on (H)	$C_{68}H_{89}IN_4O_{10},4HI=4Y+5HI+2H_2O$.
(J) Action of HI on (A)	$C_{68}H_{103}I_3N_4O_{16},4HI=4Y+7HI+8H_2O$.

Although it may well happen that further researches may show that some of the above formulæ require some slight correction, the analytical numbers not always agreeing together absolutely accurately, yet the following points may be considered established:—

(1.) The action of hydriodic acid on codeia polymerizes it, the ultimate compounds formed being derived from at least four molecules of codeia. Hydrobromic acid also polymerizes codeia, but not so completely as hydriodic acid, there being found, in addition to the tetra-bases, compounds which (from their crystalline character and other physical properties) are apparently derived from 1 molecule only of codeia. Hydrochloric acid does not appear to have a marked polymerizing effect on codeia.

(2.) Hydriodic, hydrobromic and hydrochloric acids all eliminate methyl from codeia, forming ultimately compounds containing $n\,C_{17}$.

(3.) The compounds got by the action of hydriodic acid in presence of phosphorus indicate that the carbon groups contained in codeia are in an eminently "unsaturated" condition, being capable of taking up several molecules of HI and of H_2O, forming compounds not decomposed at 100°; 2 equivalents of hydrogen for every C_{17} being also added on in every case.

PAPER MANUFACTURE IN JAPAN.

Europeans are so accustomed to attribute a great proportion of the development of civilization amongst themselves to the invention of the art of printing, and the kindred and necessary art of paper-making, that they are apt to lose sight of the fact that both arts were practised in eastern Asia centuries before they were known in Europe. With regard to the introduction of paper-making into Europe, Eustathius, who wrote towards the end of the twelfth century, stated that the Egyptian papyrus had gone into disuse but a little before his time; in Germany, at the end of the fourteenth century, the art was still a secret one, the workmen being bound by oath not to teach it to any one else, or to make paper on their own account; whilst it is doubtful whether the first paper-mill in this country was erected before the latter part of the sixteenth century. In Japan, however, paper appears to have been imported from the Corea as early as the third century, and the manufacture in that country probably dates from a period as early as the year 610 A.D. But whilst, in China, the process of printing is very much the same as it was fifteen hundred years ago, the art of paper-making, although still carried on in the rudest manner, has been so improved in Japan, that it has developed into an industry of far more importance in that country even than the corresponding manufacture in England. The list of articles fabricated by Japanese ingenuity from paper outstrips, by far, in length a similar English list, even allowing for the very considerable increase that has taken place since the removal of the paper duty. It includes such unlikely things as sun and rain umbrellas, handkerchiefs, soldiers' hats, waterproof rain coats, tobacco pouches, and string, whilst several different kinds of paper are specially prepared for ornamenting and tying up the hair. A net coat, which is worn next the skin in warm weather by the Japanese, and will wash, is made by rolling strips of strong paper into a sort of string, and then working them by hand into a neat net pattern. A paper hat, similar to our straw hats, is also made by the paper being twisted, plaited, shaped and varnished.

But the development that has at present taken place in the paper-manufacture of England has resulted in a great dearth of suitable materials for carrying it on. Almost every species of tough fibrous vegetable or animal substance, such as the roots and barks of trees, the bine of hops, the tendrils of the vine, hollyhock, cabbage and nettle-stalks, the common thistle, sugar-cane, beetroot, wood shavings, sawdust, hay, straw, willow, esparto, and the like, have been experimented upon at different times with more or less success. But the want still exists and is increasing.

It is not therefore surprising that, under these circumstances, attention should be turned towards a country in the economy of which paper-manufacture plays so large a part, and that an attempt should be made to ascertain whether any of the sources from which the Japanese obtain their supply of material could be made available to the English manufacturer. In a dispatch to Sir Harry Parkes, dated May 13, 1869, the late Lord Clarendon requested that information on the subject should be collected and transmitted to this country. The results, in the shape of three reports, from her Majesty's consuls at Kanagawa (illustrated by a very curious series of facsimiles from Japanese pictures, showing the details of the manufacture), Nagasaki and Osaka, were presented to Parliament during the last session, and have recently been printed. From these reports we propose to extract a few particulars that may prove of interest.

The manufacture of paper from the paper-mulberry (*Broussonetia papyrifera*) was introduced into Japan about A.D. 610, by Shôtoku Taishi, a son of the reigning mikado, who, seeing that the paper previously made did not take ink well, would not bear rough handling and tore very easily, and moreover was liable, because of its material, to become worm-eaten, had recourse to the paper-mulberry. From it he made four kinds, called unshi, shiku-inshi, haku-jushi, and zoku-hakushi, and he caused it to be extensively planted all over the country, and the mode of paper manufacture to be largely promulgated among the people.

In the island of Kiusiu the paper-mulberry, or makôdzu is planted in the ninth and tenth moons, but in Kioto and its vicinity in the first moon, the time varying according to the climate of the place. Some old roots are separated and cut down to a length of about three inches; these are planted so that a little less than half an inch appears above ground. They grow about a foot high in the first year, and in the second to a height of two or three feet. In the third year they reach a little over four feet; in the fourth year they attain to six, or if particularly fine, to even nine and twelve feet. Each year in the tenth moon they are cut down to the roots, and from each stalk five branches appear the next year, so that in five years a large and dense shrub is developed. The cuttings of the fifth year's growth are used for making paper. The roots will not thrive well in old ground; the best place for planting is round the edges of new-made ground or paddy-fields. They will not flourish near salt or brackish water, nor beside millet or hum. If under-manured they die, and if too much manure is used the plant is injured. If planted in the vicinity of other crops, such as rice, they rejoice in the effects of the manure which is used for their neighbours. They are sometimes planted on mounds which are raised along the beds of valleys, but newly-turned ground is the best.

The paper-mulberry suffers from sunburn in a very dry summer; while if there is too much rain it grows too fast, and is then injured by the autumnal winds. Care has to be taken to protect the plants from the ravages of wild boar and deer, which delight to feed upon them. The shrub known as "Ts'kuri-kake" is the best for making paper of, but it is scarce and expensive. There is also a variety called "kajiso," which makes good paper, but as it is more plentiful it is not so dear, though it is necessary to use a great deal of it. Another variety is called "takaso." Paper made of this is somewhat inferior, but tho shrub attains a great height, and it is not necessary to divide the roots; a cutting of it may be planted just as it is cut, and will thrive, and it does not require so much attention as the "makôdzu" as regards manure; it will also thrive in swampy ground. It needs little care, and produces a tolerably large quantity of material for paper; and at present this variety is largely cultivated. The shrubs, like other trees, bud in spring, blossom in summer, and cast their leaves in autumn: by the twelfth moon they are quite bare.

The mulberry stalks are cut into lengths of two and a half to three feet, and steamed until the skin of the stalk begins to separate at the cut ends.

After steaming, the skins are stripped from the stalks and dried. They are then tied up in bundles and exposed to the action of running water for a period varying from twelve to twenty-four hours. The outer dark skin is scraped off by drawing it under a knife that is held in a stationary position by the right hand. This dark scraping is thoroughly washed in running water, which causes it to open out flat, and boiled. It is then allowed to rot, well beaten and used in making an inferior kind of paper.

The inner fibre is taken to the river in bundles and thoroughly washed; and afterwards steeped in buckets of water. The water is run off, and heavy stones are placed upon the fibre to express the remaining liquid. It is next boiled in water in which the ashes of burnt buckwheat have been infused until all the sticky or glutinous matter is got rid of, it is then called "sosori." Great care has to be taken to secure an even boiling, and when a difficulty occurs—as it sometimes does, and is generally believed to be the work of the Inugami, or devil,—the boiling is assisted by throwing in wax-ash or common lime; but this is likely to affect the colour of the paper, and give it a reddish hue. The sosori is again washed to remove all traces of the buckwheat infusion by placing it in a basket, through which running water is allowed to percolate, and it is afterwards strained.

The night before the paper is to be made, the "sosori" should be again washed, and the next morning it is pounded for about as long a time as "it takes to boil the rice for breakfast." When paper is made in the winter, a little "tororo" must be mixed with the "sosori" before pounding; when in spring, rice paste is used as a substitute, but the paper made with rice paste is not esteemed to be of so good quality, and is liable to become worm-eaten.

The "tororo" flowers in spring; the seed is enclosed in the flower, and is small and hexagonal in shape, resembling the sesamum. Neither the flower nor the seed are of any use in the manufacture of paper, but the root is used. The shrub is not unlike the cotton plant. The root is taken after the flower has died and dried. The sprouts and skin are scraped off, and the root is then beaten. When required for use the "tororo" roots are boiled into a tolerably thin paste, and strained through a fine hair sieve.

In making the paper called "hanshi," the "sosori" to be used is made into a large ball, from which lumps are broken off as required. These lumps are cast into what is called the "boat," and thoroughly mixed with well-strained "tororo" paste.

The apparatus consists of the inner frame, the outer frame, and the false bottom, made of plaited bamboo.

The false bottom is placed in the outer frame, into which a portion of the pulp is then poured. The inner frame is next fitted in to keep the false bottom steady, and a peculiar and dexterous jerk is given to the whole, which sets the paper. The frame is then placed against the upright rest to allow the water to drain off, while another one is prepared. By the time the second frame is ready the first may be removed. This manipulation can be performed very quickly by experts in the manufacture.

The sheet of paper is removed from the frame with a piece of bamboo, by dexterously curling the thicker end of the paper round it; a brush is taken in the right hand, and with it the paper is laid on the drying-board, the side which adheres to the board being the face of the paper. Five sheets are placed on each side of the board, which is 6 feet long.

Between every 20 sheets two or three straws are inserted. The paper, in parcels of 100 sheets, is then cut and made up into bundles ready for the market.

Another source of material for paper-making in Japan is the kaji-tree, which grows more or less all over Japan, and is cultivated much in the same manner as the tea-plant and mulberry-tree. It grows to a height of some 6 or 8 feet, and thrives best in dampish ground. In some districts it is produced on the hillsides. The bark is stripped off in the autumn, and is at once ready to be used for paper-making. The branches are left either to decay or are cut away, and fresh shoots are produced before next autumn, when the same process is gone through. The tree or shrub of the kaji resembles the willow of our country, and thrives well near water and in a mild climate. It is, however, also found in the north of Japan, but does not flourish in such perfection in a cold region.

Consul Annesley writes:—"There are no reasons why the kaji-tree should not flourish in England, more especially if planted in a damp soil, and when it is considered that paper could no doubt be manufactured from this bark at a cheaper rate than it could be made from rags, added to the considerable strength it can attain, and the various useful purposes to which it can be applied, the cultivation of the kaji shrub in England is well worthy of a trial.

"Some inquiry after this bark has been made by home paper-manufacturers from merchants at this port, and samples have been sent to England, where its value will no doubt be appreciated and turned to account."

The following method is employed by the Japanese in the manufacture of paper from the bark of the kaji-tree:—The rough bark is soaked in water for several hours, and the outer rind separated; it is then again washed, then boiled, after which it is beaten with mallets until it forms a sort of pulp; then the pulp is placed in a sort of reservoir about 6 feet square and 1 foot deep, containing cold water, and is stirred about with a large flat ladle made of wood until it is entirely dissolved. A sort of size (obtained from the inner bark of a tree called "ousuke" soaked in water) is mixed with the preparation, which is now ready to be drawn up, and is effected by the help of two frames made of wood and bamboo, of such dimension as the sheet of paper is intended to assume. Between these two frames a very thin matting of bamboo is placed, which acts as a sieve, and when the preparation is drawn up, it is moved on this frame, till the required substance is obtained. The sheet thus made is then deposited on another sieve. The same process is recommenced, and when another sheet is ready it is placed over the first; a strip of straw is laid on the edge to separate each sheet, so as to obviate the risk of their adhering together, and to enable each sheet to be taken up separately. When about a dozen sheets have been thus formed into a layer, they are taken up singly and spread on boards to dry in the sun. By the same process old paper is made into fresh sheets, with the addition of a size obtained from the decoction of a creeper called "sane kadzura," which grows on the hills around Nagasaki, and gives consistency to the solution. The manufacture of old paper into new can apparently be repeated as often as desired.

A paper-cloth that is "warranted to wash" is prepared by coating the paper with a paste made by boiling and pounding a root called "kon-niaku-no-dama." From this cloth may be made boxes, trays, saucepans which sustain no injury over a charcoal heat, bags in which wine may be put and heated by insertion in boiling water, and windows that will withstand the wind and rain. Imitation leather and waterproof papers are made by mixing oil with the pulp. The juice of parsimmon is also sometimes used in making paper intended to resist damp.

It is said that the Japanese are acquainted with the method of manufacturing paper from rags, but never adopt it, preferring to make it from the bark of trees.

DOUBLE IODIDE OF MERCURY AND COPPER.

BY MM. WILLM AND CAVENTOU.

When sulphate of copper is added to a boiling solution of iodomercurate of potassium (HgK_2I_4) free iodine is disengaged abundantly, and a dark brown powder is immediately deposited, which assumes a fine red colour in cooling, and contains mercuric iodide and cuprous iodide. The salient character of this compound is that, whether suspended in water or dried, it becomes darker in colour when heated and reassumes its red colour upon cooling, without undergoing any alteration from the successive changes of temperature.

M. Mensel considers this substance to be a mixture of two iodides. The authors, on the contrary, consider that it constitutes a well-defined compound. Its colour when cold is darker than that of the mercuric iodide; and it is difficult to conceive that a mixture of red iodide of mercury and the little-coloured cuprous iodide could be darker than the mercuric iodide. Moreover, the mercurio-cuprous iodide, treated cold with iodide of potassium, is decomposed very slowly, although iodide of potassium dissolves mercuric iodide with facility. But if it be heated, the mercuric iodide dissolves and the cuprous iodide remains.

Upon submitting the cuprous iodomercurate to analysis, the authors obtained results according nearly with the formula $Hg(Cu_2)I_4$. The analysis was made by decomposing the iodide by a plate of zinc, precipitating the filtered liquor by nitrate of silver and redissolving the metals in nitric acid. The mercury was separated from the copper either by precipitating it in the state of calomel, or by treating the sulphides with nitric acid, which only dissolves the sulphide of copper. The quantity of cuprous iodide remaining after the action of boiling iodide of potassium was also determined. The formula $HgCu_2I_4$ requires 45·56 per cent. of cuprous iodide, and 46·4 per cent. was obtained.

Further evidence that there is a real combination is found in the fact, that when treated with ammonia this iodide yields two kinds of crystals, both containing mercury and copper. When the cuprous iodomercurate is boiled with ammonia a blue solution is obtained, and a very dense liquid that congeals upon a slight lowering of the temperature. The blue liquid, filtered, deposits upon cooling long blue needles, which are an ammoniacal compound of mercurio-cupric iodide. The formation of a cupric compound is easily explained by the liberation of the metallic mercury which remains in the congealed mass. The authors have not yet completed their investigation of this ammoniacal compound, it being rendered difficult by the nearly constant presence of other crystals.

The mass, dissolved by boiling water, slightly ammoniacal, yields green crystals containing both mercury and copper, the latter being in the state of copperas. These green crystals appear to be simply a product of the addition of ammonia to the mercurio-cuprous iodide. In fact, when exposed to the air or treated by an acid they reproduce the double iodide, red when cold and black-brown when heated, without loss of iodine. The blue crystals on the contrary, which are also transformed into double iodide upon desiccation, lose their iodine before losing the whole of their ammonia.

The authors consider that this preparation might be utilized in medicine.

THE SIMULTANEOUS DISTILLATION OF WATER AND CERTAIN ALCOHOLS INSOLUBLE IN WATER.*

BY MM. I. PIERRE AND E. PUCHOT.

The authors in the course of their investigation of the products of alcoholic fermentation have noticed that when a mixture of pure amylic alcohol and water is submitted to distillation, the temperature of the liquid rises rapidly to 96° C.; the liquid, at that point, enters into full ebullition, and the temperature becomes remarkably constant. The result of the distillation is a turbid mixture of water and amylic alcohol, which separates quickly into two layers; the upper consisting of amylic alcohol, the lower of water only. When the two layers of condensed liquid were examined at various times during the distillation, it was found that during the whole of the operation, as long as the temperature was maintained at 96° C., the volumes of water and amylic alcohol condensed were in the constant proportion of two to three respectively. This continued until the supply of one or other of the substances was exhausted; if the original mixture had consisted of less than two volumes of water to three of amylic alcohol, the residue was found to be amylic alcohol, but, if of more, the residue was found to be water. In the latter case the temperature rose rapidly to 100° C., in the former to 130° C.

This triple result—the uniformity of the boiling-point; a boiling-point lower than that of the most volatile of the two liquids; and the constancy of the proportions in which the two liquids distil simultaneously—appeared to the authors to point to a general law, of which it would be advantageous to find the expression, rather than to an isolated fact; they, therefore, submitted to the same process a mixture of water and butylic alcohol, which in its slight solubility resembles amylic alcohol. The ebullition was at first a little irregular and sometimes tumultuous, but was easily controlled by the addition of some pieces of platinum wire and one or two pieces of pumice-stone. In the presence of an excess of water the temperature rose to 90°·5 C., and then remained remarkably stationary until the entire disappearance of the butylic alcohol. On examining the condensed products during the distillation, it was constantly found that they were in the proportion of five parts of butylic alcohol to one part of water. If the distillation was continued after the exhaustion of one or other of the constituents of this mixture, the boiling-point rose to 100° C. if the water predominated, and to 108° C. if the butylic alcohol was in excess. Thus, in this experiment, as in the first, it was found that the boiling-point was constantly lower than that of the most volatile of the two substances, and that the proportions of the two liquids that distilled simultaneously were also constant.

In the case of the mixture of water and amylic alcohol the boiling-point was lowered—

Compared with that of water . . . . 4° C.
Compared with that of amylic alcohol . 34° C.

In the case of the mixture of water and butylic alcohol, the boiling-point was lowered—

Compared with that of water . . . 9°·5 C.
Compared with that of butylic alcohol 17°·5 C.

* Comptes Rendus, vol. lxxiii. p. 599, and *Journal de Pharmacie et de Chimie,* 4th ser. vol. xiv. p. 244.

This result having been well established, experiments were next made with a mixture of three substances, water, amylic alcohol and butylic alcohol. It was then found that in this case the temperature of ebullition was no longer constant; it rose continually from the commencement to the end of the distillation, but was always confined between 90°·5 C. and 96° C. It appeared to rise in proportion as the relative quantity of amylic alcohol in the mixture was greater.

The proportion of water which distilled over augmented with the boiling-point of the mixture; but while it was always more than one-sixth of the total product (the proportion in the mixture of water and butylic alcohol), it was always less than two-fifths of the volume (the proportion in the mixture of water and amylic alcohol).

It seems to result from this, that a mixture of water, butylic alcohol and amylic alcohol, submitted to distillation, yields a product increasingly poor in butylic alcohol and increasingly rich in amylic alcohol, and that the separation of these two substances is progressive, as it is when a mixture of them is treated in the absence of water.

Pending further investigation into this interesting subject, which it is hoped will permit of more general conclusions, the authors consider themselves justified in laying down the following propositions:—

1. When a binary mixture of water and amylic alcohol, or water and butylic alcohol, is submitted to distillation, the boiling-point remains stationary until only one of the two liquids remains in the retort.

2. The boiling-point is always below that of the most volatile liquid.

3. In each of these mixtures the relative proportions of water and alcohol which distil over are constant, but these proportions are not the same for both mixtures.

4. When a ternary mixture of water, amylic alcohol and butylic alcohol is submitted to distillation, the boiling-point no longer remains constant; it varies according to the relative proportions of the two alcohols, but always remains lower than that of the most volatile of the three liquids, and ranges between those of the two binary mixtures before mentioned.

5. The proportion of the quantity of water to that of the mixture of alcohols which passes over with it, is not constant, but augments with the temperature of the mixture; it is always, however, within the limits of the corresponding proportions previously observed in the binary mixtures, that is to say between one-fifth and two-thirds.

In a future memoir the authors propose to bring forward other analogous facts, and to attempt to draw from them conclusions that may be turned to practical account.

In a letter to M. Dumas the authors have communicated the results of a series of observations made upon a mixture of 220 cubic centimetres of distilled water (boiling-point 100° C.) and 215 cubic centimetres of amylic valerianate (boiling-point 190° C.). A great constancy was observed in the temperature of ebullition and in the relative proportions of the two liquids that passed over. The results are thus stated:—

(1.) The boiling-point of the mixture remained constant at 100° C., that is to say, at 90° below the boiling-point of amylic valerianate.

(2.) The relative proportions of the two liquids condensed remained the same as long as the retort contained an appreciable quantity of the least abundant of the two liquids.

(3.) This constant proportion was that of 65 to 35; or, more simply, 13 volumes of water against 7 volumes of amylic valerianate. In weight the proportion would be 13 to 6.

BROMINATED CAMPHOR.*

Professor Deneffe, of Ghent, states (*Presse Méd. Belge*, November 19) that for more than two years he has employed a combination of camphor and bromine, which he thinks is entitled to general attention. The celebrated chemist Laurent showed that bromine will easily unite with camphor at the ordinary temperature, but that the product is slowly decomposed by exposure to the air. M. Swartz, Professor of Chemistry at Ghent, has shown that this body heated in a closed vessel is resolved into hydrobromic acid and a crystallized compound which is monobromized camphor (*camphre monobromé*), a body differing only from ordinary camphor by the substitution of an atom of bromine for an atom of hydrogen. It is a perfectly crystallized substance, fusible at 76° C. and boiling at 274°. At Professor Swartz's request, M. Deneffe has investigated the therapeutical properties of this body, and has found it to be an excellent sedative for the nervous system. He intends shortly to publish his cases in proof of this, and, in the present communication, furnishes one of these, in which excitement of the nervous system passing into true delirium tremens was effectually relieved. He prescribed it in the form of pills, seventy grains being made into thirty pills, of which one was given every hour until twenty had been taken. For three days longer from forty-five to sixty grains were given in the twenty-four hours, the quantity being diminished from forty-five to thirty grains daily for a week longer. The recovery was progressive and stable.

THE ARTIFICIAL PRODUCTION OF CALCAREOUS SUBSTANCES, SUCH AS ARE FOUND IN THE ORGANISM.

BY M. HARTING.†

M. Harting announces in a preliminary note that he has succeeded in imitating the greater number of the forms which carbonate of lime assumes in the organism, such as biliary and other concretions, the various forms of otolites, pearls, coccolites, the spicules of the alcyonaria, the various substances which form the shells of molluscs, the calcification of cartilage, the calcareous couches of the scales of osseous fishes, etc. He has not yet succeeded in imitating the pieces of the tegumentary skeleton of the echinodermata, or the osseous substance of the vertebrate skeleton. His method of procedure was to imitate nature in regard to the length of the process. He formed the calcareous combinations in organic fluids by means of double decomposition, retarded by very slow diffusion. The paper is not yet ready in all its details.—*Journal of the Chemical Society.*

METHODS FOR DETERMINING THE QUALITY OF CASTOREUM.

BY M. HAGER.

M. Hager gives the following methods for determining the quality of castoreum:—

(1.) The taste of Siberian castoreum is much more pronounced than that of Canadian, in consequence of its greater richness in castorine, of which it contains 4·6 per cent., whilst Canadian contains but 1·98 per cent. The castorine may be easily obtained by exhausting the castoreum with pure benzine, and evaporating the product upon a watch-glass, when the castorine will be left mixed with a certain quantity of volatile oil.

(2.) Treated with chloroform, castoreum yields a sepia-brown resin, which has a stronger odour, and is more viscous in the Siberian than in the Canadian.

(3.) If powdered castoreum be treated first with alcohol and afterwards with dilute hydrochloric acid, a

* Reprinted from the *Medical Times and Gazette.*

† Compt. Rend. lxxiii. 361.

liquid is obtained, in from ten to twenty hours, which from Canadian castoreum is yellow or light brown, and from Siberian castoreum is dark brown.

(4.) The Siberian castoreum powder when macerated for some hours in an ammoniacal solution gives a darker liquid than the Canadian.

(5.) The alcoholic tincture forms with water a milky liquid, which, upon the addition of a little ammonia, becomes clear if the tincture is made with Siberian castoreum, but remains cloudy if made with Canadian.—*Journal de Pharmacie et de Chimie.*

OBSERVATIONS IN PRACTICAL PHARMACY.*

BY CHARLES SYMES, PH.D.

(*Concluded from page* 505.)

Suppositories.—These, as also pessaries and bougies, are now prepared more or less by most pharmaceutists. Those manufactured by wholesale houses are necessarily of some recognized composition and strength, and the pharmaceutist who purchases these only, finds himself awkwardly placed when they are required according to special formulæ; and in my experience this is most frequently the case. The demand, however, varies considerably in different establishments, and it becomes desirable that a simple and inexpensive means of preparing them should be in the hands of every one in the business. Some two or three years since, Mr. Redford exhibited at one of our evening meetings a small arrangement for forming tinfoil into moulds which were supported in a dish of sand; and, after trying various methods, I have fallen back on tinfoil as the simplest form of mould. It is only necessary to cut it into small pieces, and roll it round the end of a piece of hard wood shaped into the form of a suppository, bougie or pessary, as the case might be, rolling it in the palm of the hand or on the counter to remove the creases, and the mould is ready; but the support? I have found sand very inefficient unless a large surface is used; especially in the case of pessaries, they are liable to be pressed out of shape. A tin box, the lid of which drops inside to the depth of about half an inch, and which is perforated to receive metal shapes of the desired size, these being sunk below the level of the cover, forms an excellent support; it is clean to work with, the suppositories are easily removed, and in the summer, if rapid cooling is required, the box might be filled with cold water or ice and water. In the PHARMACEUTICAL JOURNAL for July a paper is published by Mr. Goodman, in which he says, referring to the materials of which suppositories are formed, "The British Pharmacopœia directs a mixture of lard and wax, which has a melting-point above the temperature of the body, viz. 140°." This gentleman had evidently got hold of the 1864 Pharmacopœia; and it struck me as being rather remarkable that such a go-ahead people as the Americans should not be aware that this volume had become obsolete, and superseded by a considerably better one in 1867; and, further, that such a statement should have been published and passed in our Journal (as far as I am aware) without comment. As you are all doubtless aware, the British Pharmacopœia directs the vehicle of suppositories to be formed chiefly of cocoa butter, with the addition of small quantities of lard and wax; but I have found cocoa butter *alone* to be much better than a mixture of the three at almost all temperatures, and, at the same time, their preparation is facilitated; in very warm weather the addition of a small quantity of pure white paraffin helps to give them consistency, and is far better than wax. In operating with the unmixed material, the medicine should be rubbed with a little of the melted butter on a warm slab, and returned to the bulk of the vehicle when it is just beginning to thicken.

Watery extracts (as of belladonna) are often prescribed in suppositories, and, in addition to being rather troublesome to prepare, they are not very efficient; in my opinion, the extract in getting divided into small particles surrounded by fatty matter is prevented, to a great extent, from acting on the mucous surface to which it is applied, and in melting the butter carries these particles away, without much effect having been produced. A more elegant and efficient suppository is prepared by rubbing the extract with grated cocoa butter in a mortar thoroughly, then slightly melt and rub together again for some little time, lastly melt and strain; this has an uniform bright green appearance, is very efficient as a medicinal agent, and might be kept ready prepared in mass, merely diluting with cocoa butter to produce suppositories of the desired strength when required. With regard to ext. opii being administered in this form, it is much less efficient than opium in powder, and is, I believe, often prescribed by medical men without any idea of this, or of the difficulty in preparation; and I think it is a duty incumbent on us to call their attention to such facts, by this means we should do away with many difficulties in dispensing, such as appear in the PHARMACEUTICAL JOURNAL weekly, and render good service to the profession.

We are all advocates of the separation of prescribing from dispensing; but if we do not take our proper position, and communicate more freely the results of our experience to the medical profession, we shall frustrate the chief object for which this separation is desirable, viz. elegance and efficiency in medicine. As further illustration of these latter remarks, let me call your attention to prescriptions containing tinctura guaiaci, such as the following:—

℞ Tinct. Guaiaci ℥ss
Pot. Bicarb. ʒij
Spt. Æther. Nit. ʒiij
Aquæ ad ℥vj. M.

Now mix these ingredients in whatever order you please and the resin will deposit in lumps, partly floating and partly adhering to the sides of the bottle, and no amount of shaking will distribute it evenly through the mixture again.

If, however, the proportionate quantity of powdered guaiacum (12 grains to ʒj) be first rubbed with a portion of the water, and in finishing the mixture the proportion of spirit equivalent to the tincture be added, a homogeneous and tolerably elegant mixture is formed, the powder being easily distributed through the fluid when required, even after it has been prepared some time.

Any medical man, accustomed to prescribe a mixture similar to the above, will readily substitute the powder for the tincture, if his attention is called to these facts.

* Read at a Meeting of the Liverpool Chemists' Association, Nov. 23, 1871.

Insecticides.—Many of the *Anathemidæ*, such as chrysanthemums, chamomiles, etc., possess in the sexual parts of the flower a narcotic matter which has a great effect upon insects, and will even kill small ones. In *Pyrethrum roseum* and *P. carneum*, just within the disk, this matter is found in considerable quantity. In order to prepare the powder to advantage, only the centre of the flower must be used, which must be cut before the seed is fully formed. The Spaniards, to keep off gnats, burn the centres of the flowers of the horse daisy (*Chrysanthemum leucanthemum*); and the powder of the mayweed (*Anthemis Cotula*) has also been used for destroying insects. In some parts of Belgium this plant is fastened by the country people to branches where swarms of bees have settled (after they have been secured), to prevent them from leaving the hive. The Mohammedans and Tartars have long employed the powder of the *Pyrethrum* against all insects indiscriminately. To destroy flies, gnats and bugs, they burn it on an iron plate, which they heat slowly, in order to produce more smoke.—*Gardeners' Chronicle.*

The Pharmaceutical Journal.

SATURDAY, DECEMBER 30, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

DRUGGISTS AND THE SALE OF BEER ADULTERANTS.

WE believe it to be a common opinion that the Pharmacy Act of 1868 is the only Act which regulates the sale of poisons, and specifies in its schedules what drugs are to be regarded as poisons. From a question which has lately been asked by a correspondent, we consider it desirable to direct attention to another Act, which may also in a certain sense be considered a Poison Regulation Act,—we mean the Act 56 GEO. III. c. 58, relating to the adulteration of beer; and, although some of the substances named therein are not poisons, those who violate its provisions render themselves liable to far more severe punishment than can be inflicted under the Pharmacy Act for the illegal sale of poisons. This Act, after specifying a great number of substances that cannot be legally used by brewers, contains the following comprehensive clause:—"Or any article or preparation whatsoever for or as a substitute for malt or hops;" a clause which is sufficiently elastic to include all articles not enumerated that can be used for the purposes named.

It will be seen from the wording of the above quotation that the offence does not consist in the addition to beer of substances deleterious to health, and that the prohibition of certain substances is simply on account of their being substitutes for articles subject to duty. We may remark, in passing, that the law in this, as in other instances, ignores altogether the public health, and has a single eye to the security of the revenue. However, this fact need occasion no surprise, for at the present time the same feeling exists, and no effort has been made, when framing very recent laws, to use language that will protect the public as well as the revenue.

To return to what constitutes adulteration under the Act, it must be mentioned that a slight modification has taken place on account of the repeal of the hop duty in 1862. Since September of that year no Excise penalty can be imposed on the brewer, dealer or retailer of beer for having or using any "article for or as a substitute for hops." This alteration, allowing brewers to receive and use any bitters, such as quassia, chiretta and gentian, restricts adulteration to those substances only which are substitutes for malt.

Whilst the brewer, dealer or retailer of beer who breaks the law is on conviction liable to a fine of £200, the druggist or other person who supplies adulterants within the meaning of the Act to any brewer, dealer or retailer of beer, *knowing* him or her to be so licensed or *reputed* to be so licensed, or shall sell, send or deliver, or cause or procure to be sold, sent or delivered, to any other person for or on account of the use of any such brewer, dealer or retailer, shall for every such offence forfeit £500. The framers of the Act were sufficiently considerate not to make the selling to a brewer, dealer or retailer of beer, an offence in the case of a person who did not at the time of sale know the occupation of the buyer. Such consideration would doubtless be of service in large towns, where brewers might with impunity obtain what they required from perfect strangers; but in country districts and small towns, where an established tradesman usually knows his customers, even if they live several miles from his place of business, there would be great difficulty in convincing a bench of magistrates that the vendor at the time of sale was ignorant of the trade of the person to whom such goods were sold.

We purposely abstained from running through the catalogue of prohibited substances when speaking of the liabilities of brewers, because we think it better to give the list in this place, when the pains and penalties attached to druggists or other dealers are under review. The Act especially mentions the following, because they are substitutes for malt, viz. molasses, honey, liquorice, vitriol, cocculus indicus, grains of paradise, Guinea pepper, opium, or any extract or preparation of the before-named substances. It is also stated to be an offence to sell, send out, or deliver to a brewer, dealer or retailer of beer any liquor called or known or sold as colouring, from whatever materials the same may have been made, for the purpose of darkening the colour of worts or beer. This restriction was found necessary, because brewers had been allowed, before the passing of this Act, to receive and use "a liquor prepared from sugar for colouring porter," and through the use of this liquor for colouring, great frauds were committed on the revenue. By a subsequent Act, however, brewers were allowed to prepare colouring from sugar on their own premises, but they cannot now legally receive any such preparation made elsewhere.

For a breach of the Pharmacy Act, as regards the sale of poisons, a fine not exceeding £5 for a first offence can be inflicted, but under the Beer Adulteration Act the fine is £500. Since the latter punishment is so severe, it might, perhaps—in the event of that part of Mr. BRUCE's Licensing Bill which deals with beer adulteration becoming law—be a matter for serious consideration whether an addition should not be made to the Pharmacy Act, specifying the articles that cannot legally be sold to brewers or dealers in beer. A conviction under the Act would, to many, be ruin; and as the Legislature considers the sale of prohibited articles to brewers and dealers in beer a more serious offence than the sale of poisons to the public, it cannot be said that the subject is too unimportant for action to be taken in the matter. The law supposes every man who embarks in any trade to be acquainted with the Acts of Parliament governing that trade, and on this account we have directed attention to the Act 56 Geo. III. c. 58, to impress upon our readers the necessity of exercising great caution when trading with brewers or other persons engaged in the beer trade.

MEDICAL DECLARATION RESPECTING ALCOHOL.

A memorandum has been published on the subject of the duty of medical men in regard to the prescribing of alcohol, which, from the long list of honourable and influential names appended to it, irrespective of the importance of the subject, merits careful consideration. It is as follows:—

"As it is believed that the inconsiderate prescription of large quantities of alcoholic liquids by medical men for their patients has given rise, in many instances, to the formation of intemperate habits, the undersigned, while unable to abandon the use of alcohol in the treatment of certain cases of disease, are yet of opinion that no medical practitioner should prescribe it without a sense of grave responsibility. They believe that alcohol, in whatever form, should be prescribed with as much care as any powerful drug, and that the directions for its use should be so framed as not to be interpreted as a sanction for excess, or necessarily for the continuance of its use when the occasion is past.

"They are also of opinion that many people immensely exaggerate the value of alcohol as an article of diet; and since no class of men see so much of its ill effects, and possess such power to restrain its abuse, as members of their own profession, they hold that every medical practitioner is bound to exert his utmost influence to inculcate habits of great moderation in the use of alcoholic liquids.

"Being also firmly convinced that the great amount of drinking of alcoholic liquors among the working classes of this country is one of the greatest evils of the day, destroying, more than anything else, the health, happiness and welfare of those classes, and neutralizing, to a large extent, the great industrial prosperity which Providence has placed within the reach of this nation, the undersigned would gladly support any wise legislation which would tend to restrict, within proper limits, the use of alcoholic beverages, and gradually introduce habits of temperance."

Doubtless this memorandum will give rise to considerable discussion and divergence of opinion, but in any case the *British Medical Journal* and the *Lancet* are in accord on this subject (not being too closely connected with "circulation"); for while the one informs us the memorandum had its origin at an interview between the Secretary of the Temperance League and Mr. Ernest Hart, consequent upon some editorial remarks which appeared last September in its columns, the *Lancet* refers to sentiments expressed in an article published six weeks ago, as being in some cases very similar to, if not identical with, some points of the memorandum.

The *Medical Times and Gazette*, however, considers that there is a certain vagueness in the opening sentence, which might be construed to imply that the signataries believe medical men to be responsible for a large part of the intemperance of the day. Mr. F. C. Skey also, in a letter to the *Times*, objects to the memorandum as being "dictatorial, assailing the deliberate judgment of a large number of eminent members of the profession." He also doubts the existence of the "many instances" of "intemperate habits engendered by the medical administration of alcohol." And from a letter published in the *Medical Times and Gazette*, this opinion appears to be shared by Dr. Lionel Beale.

Another class who may be expected to express an opinion upon the matter are those who consider that the nature of the alcoholic drink makes a great difference, for at the recent meeting of the St. Andrew's Medical Graduates' Association, when Dr. B. W. Richardson pointed out that the different alcohols—ethylic, methylic, amylic, etc.—had very different physiological actions, this point was further illustrated by Dr. Shorthouse, who said he could support Dr. Richardson's opinion by great practical experience. He thought that effervescing wines were far less harmful than sherry or even bitter ale, and, amid great laughter, proceeded to inform the meeting of the quantity of champagne he drank daily. Champagne, he said, never did him any harm; he had drunk some before coming to the meeting, and would pledge himself at that minute to "thread a needle or to pick a flea's eye out."

THE CHICAGO COLLEGE FUND.

Professor Attfield, writing from the country, tells us that he is preparing a third list of donations for publication in the next number of the Pharmaceutical Journal. Contributions from provincial towns are beginning to flow in; subscriptions and books having been received from Edinburgh and Colchester. The Council of the Chemical Society has also presented a set of the Journal and Transactions.

The first election of Council of the Ontario College of Pharmacy, under the Ontario Pharmacy Act passed last February, has taken place. We notice that Mr. William Saunders and Mr. E. B. Shuttleworth (editor of the *Canadian Pharmaceutical Journal*) are respectively first and third on the list.

At the last Evening Meeting, Dr. Tilden called attention to a cabinet for holding labels so arranged as to prevent the confusion that sometimes arises from their becoming mixed. Though apparently only a matter of detail, the importance that may attach to it is shown by a case reported at p. 538, where the affixing of a poison-label to a harmless compound caused the druggist some anxiety; but had the conditions been reversed, and a poison been improperly labelled, the consequences might have been much more serious to him.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

December 20th and 22nd, 1871.

MAJOR.

The following five candidates presented themselves for the Major Examination, and, having passed, were declared duly qualified to be registered as Pharmaceutical Chemists:—

Brown, Frederic Peter ...... Grantham.
Jones, William Ellis .... Barmouth.
Keen, Benjamin .... Uppingham.
Brown, James .... Ampthill.
Forsbrook, William Henry.... Birmingham.

MINOR.

Forty-four candidates presented themselves for the Minor Examination; of these, *seventeen* failed. The following *twenty-seven* passed, and were declared duly qualified to be registered as Chemists and Druggists:—

*Greenish, Thomas Edward .. London.
*Stocks, Charles .... London.
*Kendall, Edward Basnipp .. Nottingham.
Equal. { *Cooper, Frederick Richard .. Manchester.
{ *Grace, Charles .... Hammersmith.
Equal. { *Canner, William............ Derby.
{ *Dale, John .... Birmingham.
Tucker, William Tyley...... Worthing.
Williamson, Nicholas ...... Whitehaven.
Goodlad, John Jonathan .... Birmingham.
Hockenhull, Philip Hall .... Macclesfield.
Windle, John Thomas ...... Norwood.
Place, John Newton .... Cambridge.
Hall, Edwin .... Weston-super-Mare.
Hensby, Robert Place ...... Maidstone.
Hawley, William .... London.
Springett, Normington ...... London.
Tuck, William James ...... Portsmouth.
Perks, Samuel Woodhouse ... Brighton.
Tamplin, George W. D. H. .. Bristol.
Jones, Morgan .... Chipping-Sodbury.
Oliver, Frederick Bailey ..... London.
Rossiter, John .... London.
Bannerman, Chas. Alexander Belfast.
Simpson, John.............. Lewes.
Lea, Harry .... Ellesmere.
Saul, William Benjamin .... Taunton.

The above names are arranged in order of merit.

PRELIMINARY.

Certificates were received from the undermentioned in lieu of this examination:—

Davenport, Thomas .... Wrexham.
(*Certificate of the College of Preceptors.*)

Thomas, Archibald .... Northampton.
(*Certificate of the Law Society.*)

Trood, Richard .... Bath.
Wright, Watkin Valentine.... Wrexham.
(*Certificates of the College of Preceptors.*)

* Passed with honours.

NORTH BRITISH BRANCH OF THE PHARMACEUTICAL SOCIETY.

The Second Meeting of the present Session was held in Craigie Hall, 5, St. Andrew Square, Edinburgh, on Wednesday evening, 20th December, at 8.30; Mr. Baildon, President, in the chair. There was a very full attendance.

After a few remarks by the Chairman, an interesting lecture was delivered by Dr. Stevenson Macadam, on "The Colouring Agents recently derived from Coal Tar." The subject was fully illustrated by diagrams and accompaniments, and at its conclusion the President proposed a cordial vote of thanks to Dr. Macadam. This was seconded by Mr. J. R. Young, and carried by acclamation. Dr. Macadam having replied, the meeting adjourned.

Provincial Transactions.

LEEDS CHEMISTS' ASSOCIATION.

The Third Meeting of the Session was held in the Clergy Room, Church Institute, on Thursday, December 21, 1871; the President, Mr. E. Brown, in the chair.

The minutes of the last meeting having been read and confirmed, Mr. Clapham was elected a member, and Messrs. J. W. Clapham, Shaw, Tingle, and J. Winder were elected associates.

Mr. Smeeton, referring to the Early Closing movement, could not report favourably of the chemists upon whom he was deputed to call; there appeared a disposition to close, but the want of unanimity was fatal to the cause.

Mr. T. B. Stead then read the paper of the evening, entitled "A Retrospective Glance of the Trade." During the reading of the paper, which had reference more particularly to local incidents, Mr. Stead observed that the promoters of the Early Closing movement might have occasion to regret the steps they were taking, inasmuch as if the assistants and apprentices instead of properly using the time squandered it away, more evil than good would be done.

Mr. Smeeton proposed a vote of thanks to Mr. Stead for his paper, which was seconded by Mr. Day.

The President had pleasure in supporting the vote of thanks, though he could not quite agree with the remarks referring to the earlier closing of chemists' establishments. It was quite true there was a doubt as to the manner in which some assistants would use the time thus allowed, but they were of an age to be answerable for their own deeds, and every master who took a proper interest in his apprentice would endeavour to guard against the danger referred to. According to the letters which had appeared during the past few months in the Pharmaceutical Journal, it would seem as though the writers ignored much of the practical work which formerly entered into the education of apprentices; the powdering of drugs in the iron mortar was now of rare occurrence, in consequence of the introduction of mechanical power, nevertheless he considered that every youth should have some practical work of this character. There seemed a growing disposition to leave the scientific education of apprentices to be conducted in schools of pharmacy.

The resolution was carried.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, December 21, 1871; Professor Williamson, F.R.S., Vice-President, in the chair.

The usual business of the Society having been transacted, the Chairman announced that Professor Canizzaro had consented to deliver the Faraday lecture.

A paper was then read by Mr. H. Bassett, F.C.S., "On Eulyte and Dyslyte," two beautifully crystalline compounds obtained by the action of nitric acid on citraconic acid, a product of the dry distillation of citric acid. The two substances each contain nitrogen, but owing to the comparatively small quantity obtained, namely, somewhat less than two ounces from thirty pounds of citric acid, the author has as yet been unable to thoroughly investigate their nature.

Professor Armstrong also read a paper on "The Nitration Products of the Dichlorophenol Sulphuric Acids," being a continuation of his researches on the nitrochlorophenols.

The meeting then adjourned until the 18th of January, 1872.

ROYAL SOCIETY OF EDINBURGH.

Sir Robert Christison on the Fresh Waters of Scotland.

At the First Ordinary Meeting of the Royal Society of Edinburgh for the present session, held on Monday, December 4, the President, Sir Robert Christison, described some recent observations on the fresh waters of Scotland. These observations were classified by him under three heads—(1) the composition of the water of certain of the fresh-water lakes and of the streams which feed them, and the changes undergone by the waters of the streams which are fed by the lakes; (2) the temperature of the water at various depths in the lakes; and (3) the action of the waters on lead. He first directed attention to the general geological structure of this country, by which, in a great measure, the properties of the Scottish fresh waters are regulated. Generally, and particularly in the Highlands, the mountain summits are very pointed or rugged, and the mountains abound in precipices, crags and loose rocks, and the intermediate valleys, except in the course of the large rivers, are narrow and stony, and capable of little or no cultivation. Sometimes, however, and this chiefly in the Lowland hills, the spurs are ridgy and at times separated by upland valleys, boggy and abounding in peat. From this structure it followed that in most districts of the Highlands rain or snow took but little time to descend in streams to the lower grounds; and so the water of the Highland streams was uncommonly pure in dry weather, and not much less so in other kinds of weather. In the lower country streams generally were nearly as pure. The water of streams near Lochgoilhead might be taken as a fair type of the streams which feed the fresh-water lochs in that district; and the general results of some observations made last summer were, (1) that the water of those streams was almost entirely free from colour; (2), that, like most of the Highland streams, it contained a very small portion of saline and of organic matter—so small, that the ordinary tests scarcely affected the waters, the hardness of the water being about one-tenth that of the Edinburgh water; (3), that the water would affect lead. In winter time there was not so great a difference in the composition of the water as might naturally be expected. It assumed a somewhat brownish colour, but otherwise its purity was very great, and its effect on lead was, at the same time, more rapid. During long drought the composition of the water of the streamlets was much that of the springs from which in such times the streamlets were fed, and spring water had more saline matter, but was always colourless. The water of the lakes fed by these streams was much that of the streams. The water of the lowland lakes was somewhat differently constituted.

From want of time, Sir Robert Christison deferred the discussion of the last topic, the action of the waters on lead, to another opportunity.

PHILADELPHIA COLLEGE OF PHARMACY.

The Second Meeting of the session 1871–72 was held on Tuesday afternoon, Nov. 21, 1871; Dr. Wilson H. Pile presiding.

Mr. Charles Heinitsh, of Lancaster, Pa., presented a sample of capsicum, bearing a very small fruit, finely flavoured. It was raised from seeds brought from Mexico during the war. The species seems to be unknown.

Professor Maisch exhibited specimens of cundurango, received, since the last pharmaceutical meeting, from various parties. The flowering-branch and the pod of that variety of cundurango called "mata-perro," sent for exhibition by M'Kesson and Robbins, of New York, belong to a plant of the Natural Order *Asclepiadaceæ*, though not to the genus *Asclepias*. Authentic specimens of mata-perro, tumbo grande and tumbo chico, received from the same house, were likewise exhibited, and compared with a specimen coming from the State Department at Washington. The latter is a piece from a young branch, and probably identical with the tumbo grande, which, however, consists, in the specimens exhibited, of older bark only. The experiments of physicians with the cundurango first received in this country have not sustained its reputation. It remains to be seen whether mata-perro and tumbo chico possess valuablo medicinal properties; for the former, alterative properties and beneficial effects in syphilitic complaints are claimed. Various samples of cundurango met with in commerce consist of mata-perro and tumbo chico, the latter sometimes mixed with small and variable quantities of tumbo grande. The appearance of the decoctions of the three varieties, and their behaviour to ammonia and nitric acid, afford no reliable means of distinguishing them, as had been stated in a circular lately received.

Professor Maisch also exhibited South American and East Indian clove or culilawan bark. The former comes from *Dicypellium caryophyllatum*, Nees, and occurs in large quills, composed of several layers of the thin liber; the latter is the produce of *Cinnamomum Culilawan*, Nees, and comes in flat pieces, the taste resembling a mixture of cloves, cinnamon and sassafras.

Professor Parrish presented specimens of "Boldo" leaves and branches, brought by Dr. E. W. Burton from Concepcion, in Southern Chili, where it has a reputation among physicians and people as a specific remedy in chronic liver complaints. The tree was supposed by Dr. Burton to be a species of *Drimys*, probably *Drimys chilensis*, but the leaves are opposite, while those of all the *Magnoliaceæ* are alternate. The tree is an evergreen, growing 20 feet high, and is very abundant. The twigs or small branches are covered with a thin bark, perhaps a line in thickness, firmly adherent to the tough and fibrous wood. The wood is slightly, the bark very, aromatic; it is wrinkled longitudinally, covered with vesicles, light brown or fawn colour, much branched, with opposite very numerous branchlets; the terminal branches are very bushy. The leaves—which are described as of a dark though lively green colour on the upper surface, lighter on the under when fresh—are in this dry specimen reddish-brown, mottled with whitish spots, coriaceous, deeply marked with midrib and alternate, sometimes opposite veins, which are anastomosed and looped near the edges. They are conspicuously covered with vesicles and very aromatic, opposite, petiolate, entire, ovate, with a small stipule at the base. The flavour is grateful, and recalls that of chenopodium. The medicinal virtues of this tree were discovered by its marvellous effect on a flock of sheep enclosed in a corral formed of this tree. The sheep were much afflicted with a disease attributed to the liver, and by browsing on the leaves of the Boldo, constituting their enclosure, were restored to health. Large quantities of this drug are said to be exported from Chili to Peru, where it is highly valued.

Professor MAISCH read a paper on fluid extract of chestnut leaves.

Professor PARRISH exhibited specimens of "Perkins and Hyatt's Celluloid Base," patented for the use of dentists in making artificial dentures. This is composed of inspissated collodion combined with a certain proportion of camphor. At the temperature of 300° F. it softens so as to be perfectly adapted to the plaster cast of the mouth, and when cold is firm and somewhat elastic, much resembling the hard rubber plates so much in use. He also showed a convenient screw-press, flask and oil-bath, with thermometer attached, in which the base is moulded to fit the plaster cast. Although adapted to withstand any test experienced in actual use in the mouth, this substance is soluble in ether and alcohol, and at a temperature of about 330° F. is decomposed and volatilized. Touched by an ignited match, it was shown to burn rapidly, with much smoke.

Dr. PILE exhibited crystallized bromide of morphia, prepared by him by double decomposition between equivalent quantities of bromide of barium and sulphate of morphia. The crystals, which are very beautiful, acicular, and disposed in stellate groups, are very difficult to dry without losing their whiteness. He stated that this salt is sometimes prescribed as a remedy in nervous affections.

Dr. BRIDGES remarked that bromide of potassium has been found useful in correcting the effects of opium, and this combination may have been suggested by a knowledge of that fact.

Professor PARRISH exhibited so-called "divided medicines," patented by Fred. Kraus, of Cincinnati. They consist of sheets of gelatine containing, either in solution or suspended equally throughout, such medicines as calomel, opium, subnitrate of bismuth, sulphate of quinia, sulphate of morphia, and arsenious acid. Being of uniform thickness and definite outline, they are marked while yet soft with lines dividing them into twelve equal squares, each of which, by being cut out, will furnish a definite dose. He stated an objection to this form of administering soluble medicines, that the full impression is made upon the palate during their solution in the mouth, which must necessarily be protracted; the French wafer, on the contrary, by enveloping a nauseous medicine, so as to prevent its contact with the organs of taste, completely disguises it. The effect of moisture upon these gelatine sheets would seem to render them more perishable than many other pharmaceutical forms.

In the discussion which followed upon the eligibility of these medicines, Professor MAISCH spoke of their having been used in Germany and other parts of Europe for several years, and being first suggested and introduced by Professor Almén, of Upsala, Sweden. The elegant atropine and calabar disks of Squire, and those containing a variety of concentrated remedies made by Savory and Moore, are similar, though of greatly superior workmanship, and are especially adapted to be applied in the eye and for similar applications.

Professor MAISCH called attention to the recent observations in regard to the solvent action of citrate of ammonia, potash, soda and lithia upon various salts of iron and bismuth insoluble in water, and exhibited scales resembling the officinal pyrophosphate of iron, but composed of phosphate of sesquioxide of iron and citrate of potash. This salt was made by Mr. J. Creuse, of Brooklyn. It is surprising how long a time it took to make this discovery, while it has been well known for a number of years that soluble salts of iron, mixed with sufficient citric or tartaric acid, are not precipitated by potash, which has generally been attributed to the formation of a double salt. The discovery by Robiquet, in 1856, of the solubility of pyrophosphate of iron, and the observation by several, in 1859, of the solubility of the ordinary phosphate of iron in citrate of ammonia, failed to provoke similar experiments with citrate of potash and of soda, until the present time, by Mr. Creuse.

SOCIETY OF ARTS.

DYES AND DYE-STUFFS OTHER THAN ANILINE.*

BY DR. CRACE-CALVERT, F.R.S.

LECTURE III.

Blue Colouring Substances.—Indigo, Orchil, Cudbear, Litmus, Prussian Blue and Ultramarine.

(*Continued from page* 515.)

Returning from this digression, let us now enter on a description of the process of M. Marnas. He treated the lichens, as suggested by Dr. Stenhouse, with milk of lime, filtered the lime liquor off, precipitated the colour-giving principle from it with hydrochloric acid, and gathered the precipitate on a filter. This precipitate was well washed, dissolved in caustic ammonia, and the ammoniacal liquor kept at a temperature of 153° to 160° for twenty to twenty-five days, when, under the influence of that temperature, the colour-giving principles of the lichens fix ammonia and oxygen, and are transformed into a new series of products. These were separated from the liquid by the addition of chloride of calcium, which caused a fine purple lake to be deposited. This, after being washed and dried, was sold under the name of French purple.

To dye silk or wool with French purple, it is simply necessary to mix the lake with its weight of oxalic acid, boil with water, and then filter, the oxalate of lime remaining on the filter, while the colour passes through in the filtrate. This liquor is added to a slightly ammoniacal liquid in the dye-beck; all that is now necessary is to dip the silk or wool in the beck, when it will become dyed with magnificent purple or mauve.

To dye cotton, it is necessary to mordant it with albumen, or prepare it as for Turkey red, before putting it in the bath.

Robiquet was the first chemist to isolate a colourless principle from lichens susceptible of assuming a fine purple hue when brought in contact with ammonia and oxygen. This principle he named *orcine.* He obtained it by treating the *Variolaria orcina* by strong alcohol. This solution, on being allowed to cool, gives crystals, which, on being dissolved in water and allowed to crystallize, assume the form of large well-defined crystals of hydrate of orcine. By crystallization from ether anhydrous orcine can be obtained. Orcine gives a fine dark-red colour with perchloride of iron; but its most remarkable property is its transformation into *orcëine,* which Robiquet shows to be due to the following reaction:—

$$\underset{\text{Orcine.}}{C_7H_8O_2} + \underset{\text{Ammonia.}}{NH_3} + O_2 = \underset{\text{Orcëine.}}{C_7H_9NO_3} + \underset{\text{Water.}}{H_2O}.$$

Orcëine presents itself under the form of a brown powder, slightly soluble in cold water, to which it gives a red colour. It is soluble in alcohol, but insoluble in ether. It is soluble in alkalis and ammonia, to which it communicates a magnificent violet colour. It exists in commercial orchil under the form of orcëinate of ammonia.

Time will not permit me to describe the researches of Heeran and Sir R. Kane. I must therefore confine myself principally to a short description of those of Dr. Stenhouse and Dr. Schunck.

The chief merit of Dr. Schunck consists in having pointed out the connection which exists between the orcine of Robiquet, and the *erythrine* and *pseudo-erythrine* of Heeran, and in showing that orcine is the sole immediate colour-producing principle of the series. This he proved by his researches published in 1842, in which he treated the dried and powdered *Variolaria orcina*

* Cantor Lecture, delivered Tuesday, Feb. 21. Reprinted from the *Journal of the Society of Arts.*

by ether. On evaporating this solution, there remained a residue, from which he isolated a substance which he called *lecanorine* or *lecanoric acid*. This compound crystallizes in white needles, and gives a red colour with bleaching-powder, and a dark purple with perchloride of iron. It yields a similar colour when dissolved in ammonia and exposed to the atmosphere. Its most interesting property is its conversion into orcine and carbonic acid when boiled with an aqueous solution of baryta. The reaction is—

$$\underset{\text{Lecanorine.}}{C_8H_8O_4} = \underset{\text{Orcine.}}{C_7H_8O_2} + \underset{\text{Carbonic acid.}}{CO_2}.$$

He found also that on boiling lecanorine with alcohol it formed an ether, which proved to be identical with the pseudo-erythrine of Heeran.

Dr. Stenhouse has succeeded in extracting the important compounds to which he has given the names of *erythrite* and *orsellic acids*. The first-mentioned body is a product of the decomposition of erythrine under the influence of lime-water. The erythrine splits up into carbonic acid, orcine and erythrite, according to the following equation:—

$$\underset{\text{Erythrine.}}{C_{12}H_{16}O_7 + H_2O}$$
$$= \underset{\text{Erythrite.}}{C_4H_{10}O_4} + \underset{\text{Orcine.}}{C_7H_8O_2} + \underset{\text{Carbonic acid.}}{CO_2}.$$

The orsellic acids were obtained, one from the South American weed, the other from the South African. The first appears to be identical in composition with lecanorine, and is capable of splitting up under the influence of baryta or lime into carbonic acid and orcine. The one from the latter appears to be composed of lecanoric acid and a substance called roccellinine. According to Schützenberger, lecanoric acid may be made to undergo a decomposition into orsellic acid, or may be further converted into orcine.

The employment of orchil is at the present day comparatively limited, but it is still used for producing browns, maroons and other dark shades, in conjunction with other dye-stuffs. Its chief use is to top cheap indigo blues on woollen goods; this is effected by lightly dyeing the fabric with indigo (an expensive dye), and then passing it through a bath of orchil, which gives to the cloth a rich purple hue, similar in appearance to one dyed wholly with indigo.

Cudbear is a special preparation of orchil, first manufactured by Dr. Cuthbert Gordon, from whom it derives its name.

Litmus is obtained from the same lichens as those employed for producing orchil, only lime and carbonate of potash are added to the ground weed and urine; in fact, the process is very similar to that used in former times to produce orchil. After three or four weeks, a blue colour is fully developed, when it is mixed with sulphate of lime or chalk, dried, and is ready for market. The chief employment of litmus is to communicate a peculiar tint to the cheese made in Holland.

Prussian Blue.—I shall now have the pleasure of drawing your attention to one of the finest, brightest and most permanent colours known. It was discovered accidentally in 1710 by a colour manufacturer named Diesbach, of Berlin, from which it derived its name. The process by which it was produced was kept a comparative secret until 1724, when Dr. Woodward showed how the colour had become a very profitable affair, and described a process by which it could be obtained. The process has in time undergone many improvements; but I shall here confine myself to a description of it as now carried out. I shall be obliged here to enter slightly into theoretical chemistry.

Prussian blue is a combination of iron with *cyanogen*, a compound of carbon and nitrogen. There are two well-defined cyanides of iron corresponding to the two oxides, the *proto-cyanide*, Fe Cy, and the *sesquicyanide*, Fe_2Cy_3. These two cyanides, combining together in different proportions, give rise to the various shades of Prussian blue found in commerce. But, strange to say, you cannot produce either of these compounds, or Prussian blue, by the direct combination of cyanogen with iron. Cyanogen must be first united with potassium, giving rise to cyanide of potassium, under the influence of which salt the iron combines with cyanogen, and the cyanide of iron thus formed in its turn combines with the cyanide of potassium, forming a double cyanide. There are two double cyanides of potassium and iron; the first, called ferrocyanide of potassium, or yellow prussiate of potash; the second, ferri-cyanide, or red prussiate of potash. The formula may be represented as follows:—

Yellow prussiate . . Fe Cy + K Cy
Red prussiate . . . $Fe_2Cy_3 + 3KCy$.

To produce Prussian blue from these salts, it is necessary to replace the potassium by iron. This is effected by adding a persalt of iron to the yellow prussiate, or to the red prussiate a proto-salt of iron. The iron of the iron salt replaces the potassium of the double salts, and double cyanides of iron are produced, as seen by the following formulæ:—

$$\underset{\text{Yellow prussiate.}}{3(FeCyKCy)} + \underset{\text{Sesquichloride of iron.}}{Fe_2Cl_3} = \underset{\text{Prussian blue.}}{3FeCyFe_2Cy_3}$$
$$+ \underset{\text{Chloride of potassium.}}{3KCl.}$$

$$\underset{\text{Red prussiate.}}{Fe_2Cy3KCy} + \underset{\text{Protochloride of iron.}}{3FeCl} = \underset{\text{Prussian blue.}}{Fe_2Cy_3 3FeCy}$$
$$+ \underset{\text{Chloride of potassium.}}{3KCl.}$$

That this is the case can be easily demonstrated, for if you mix together a solution of persalt of iron and one of red prussiate, which contains only percyanide of iron, no Prussian blue is formed. Again, if you mix yellow prussiate of potash with protochloride of iron, you get no Prussian blue, because, in the first case, you have no protocyanide of iron present, and, in the second, you have no percyanide.

Simple as the production of Prussian blue appears, it requires much practice to prepare it with certainty as a pigment where a given shade of blue is required. It is seldom found pure in commerce, being generally mixed with starch, chalk or gypsum. Sometimes they are added with a view to deception, sometimes in order to produce a lighter shade of colour. The testing of a Prussian blue by chemical means is not, therefore, a true criterion of its quality. The method usually employed consists in grinding in oil equal weights of a Prussian blue of known value and of the one to be tested, white lead is added to each, and the intensity of the colours compared.

The best quality of Prussian blue is obtained by mixing a dilute solution of red prussiate of potash with protosalt of iron; the second quality is made by mixing yellow prussiate of potash with pernitrate of iron, and is called *Turnbull's blue*. Cheaper qualities are made by mixing solutions of yellow prussiate and protosulphate of iron (green copperas), which produces a pale blue precipitate. This is transformed into Prussian blue by the addition of bleaching-powder, which oxidizes part of the iron, and transforms the protocyanide into percyanide. For still lower qualities, alum is mixed with the iron solution previously to the prussiate being added. Alumina is by this means mixed with the blue.

Prussian blue was first obtained on silk fabrics in 1811 by a professor of chemistry at Lyons, named Raymond, in consequence of the high premium offered by the first Napoleon for the production of a fast blue, as indigo could not at that time be imported into France. His process, with slight modifications, is followed at the present day, although the colour is not much used, owing to the introduction of the aniline blues. It consists in dipping the silk, for several hours, in a salt of peroxide of iron, when the oxide of iron becomes fixed in the silk, which is washed and dipped in a slightly acid solution of yellow prussiate of potash. Prussian blue is thus produced on the silk, which only requires washing to be ready for market. The only improvement made in this class of dyeing has been the addition of a persalt of tin to the iron-salt.

The production of Prussian blue on cotton or woollen fibres is effected by a curious chemical reaction. At a temperature of 212° F., all acids, even the organic, such as oxalic, citric and tartaric, as well as the acid sulphates, possess the property of decomposing the two prussiates. The potassium of the cyanide combines with oxygen of the water and with the organic acid. The cyanogen thus liberated unites with the hydrogen of the water, forming prussic acid. The cyanide of iron liberated unites with the fibre of the cloth, and on the latter being passed into a weak solution of bichromate of potash or bleaching powder, or if it is left exposed to the air, part of the protocyanide of iron is converted into sesquicyanide, and Prussian blue is produced. As salts of tin greatly facilitate the fixing of the prussiate on the cloth, chloride of tin is now generally mixed with the prussiate of potash. In this case prussiate of tin is produced. To this mixture tartaric or oxalic acid is added; it is then properly thickened and printed on the calico. When the design is dry, the fabric is submitted to the action of steam, and the blue is produced on the fabric. It then only requires to be passed through a bath of bichromate of potash to develope the full depth of the shade.

Ultramarine Blue is a most valuable pigment, both on account of its cheapness and the brilliancy of its colour. It is used extensively in many branches of trade—by the calico-printer in pigment printing, by the paper-stainer and manufacturer, the typographic and lithographic printer, by the match manufacturer, the sugar refiner, and by the house decorator. The value of the pigment depends on the fineness of the powder and the brilliancy of its hue.

The greatest care and much experience are required in every stage of the manufacture, in purifying the substances employed, in mixing, in heating at the proper temperature, and in grinding, washing, and drying the manufactured mass. Fourteen distinct operations are required to produce it, and it would take too much time at this late hour to enter into the details of these processes. I will therefore only attempt to give you a very rough outline of the principal points of the manufacture.

The proportion of materials used may be as follows:—

White china, clay or kaolin	50	parts.
Sulphate of soda	19	„
Sulphur	25	„
Charcoal	12	„
Carbonate of soda	28	„
	134	

These substances are most intimately mixed together, and introduced into an earthenware crucible, which is carefully closed and heated at a temperature of about 500° F. for twelve hours. The temperature is then gradually raised till it reaches a white heat at the end of forty-eight hours; the fire is then removed, and the crucible allowed to cool gradually in the furnace. The mass, as taken out of the crucible, is of a beautiful bright green colour. It is ground, washed and dried, and then calcined in an open furnace to oxidize it; but as the slightest excess of oxidation spoils the colour, the workman from time to time adds a small amount of sulphur to the mass, by this means controlling the oxidation. The green mass gradually becomes blue, and is washed and dried, when it is ready for market.

The colouring matter of ultramarine is not well known. It is supposed to be a peculiar sulphate or hyposulphite of soda. The solid matter itself is a double silicate of soda and alumina. What is certainly worth notice is that, although we are ignorant of the true colouring matter of this pigment, we find its composition to be almost identical with that of the natural *Lapis lazuli*, which, although very costly, was employed by painters for many centuries. The following analyses will show the similarity of composition:—

	Lapis lazuli.	Ultramarine.
Silica	45·40	46·60
Alumina	31·67	23·30
Soda	9·09	21·46
Potash	*nil*	1·75
Iron	0·52	1·00
Lime	3·52	0·02
Sulphuric acid	5·89	3·08
Sulphur	0·95	1·68
Chlorine	0·42	trace
Water	0·12	*nil*
Loss	2·42	1·05
	100·00	100·00

Artificial ultramarine was discovered by a French chemist and druggist, named Guimet, who kept the process of its manufacture secret for many years.

Quercitron, Fustic, Persian Berries, Weld, Aloes, Turmeric, Annatto, Ilixanthine, Lakao, Tannin matters, Gall-nuts, Sumach, Divi-divi, Myrobalans, Catechu.

I shall have the pleasure of devoting the first part of this lecture to some of the most useful and important yellow substances used by dyers and calico-printers, and to one or two other colouring matters which, although scarcely commercially important, are interesting from a scientific point of view.

Among the most valuable of these bodies is *quercitron*, the bark (from which the epidermis has been removed) of a particular species of oak, called the *Quercus nigra* or *Quercus tinctoria*. This tree is indigenous to the United States of America, and is especially found in the forests of Pennsylvania, Georgia, and in North and South Carolina. A chemist, of the name of Bancroft, first introduced it to the English dyers in the year 1775. The most esteemed qualities are those imported from Philadelphia, New York and Baltimore. The bark, after being removed from the tree, is dried, and ground between millstones. The value of a sample bears a direct ratio to the fineness of the powder, for the woody fibre of the bark, which contains only a small quantity of colouring principle, is not easily reduced to a fine powder.

M. Chevreul was the first chemist who examined this dye, and he found it to contain a peculiar tannin, which has since received the name of *quercitannic acid*, and a yellow colouring principle, to which he gave the name of *quercitrin*, but which has since received the name of *quercitric acid* from M. Bolley.

M. Chevreul, by boiling quercitron bark in water, and allowing the aqueous solution to stand, obtained fine, laminated crystals, which were gradually deposited, and to which he gave the name of quercitrin.

M. Bolley followed a better process. He treated the bark by alcohol, precipitated the tannin from the alcoholic solution by gelatine, evaporated the alcohol, and obtained the quercitrin under the form of colourless crystals. These, under the influence of air or oxidizing agents, assume a bright yellow colour. The alkalis give quercitron a brownish tint, but its most characteristic property is to give a greenish-yellow precipitate with chloride of iron, and a beautiful bright yellow precipitate with protochloride and oxymuriate of tin.

M. Rigaud discovered, a few years since, by boiling quercitrin with water containing 10 per cent. of sulphuric acid, that it is a glucoside, which decomposes under the influence of the acid into glucose and quercetin according to the following formulæ:—

$$\underset{\text{Quercitrin.}}{C_{36}H_{40}O_{21}} + \underset{\text{Water.}}{2H_2O} = \underset{\text{Glucose.}}{2(C_6H_{12}O_6)} + \underset{\text{Quercetin.}}{C_{24}H_{20}O_{11}}.$$

Quercetin is a crystalline powder, of a bright lemon colour, and of a much richer hue than quercitrin. It has no taste, is insoluble in cold water, and only slightly soluble in hot, but is freely soluble in alcohol. It is soluble in alkalis, to which it communicates an orange-yellow hue. Its alcoholic solution gives orange precipitates with the salts of lime, baryta and lead. It assumes an orange colour with perchloride of iron.

Although quercitron bark gives a fine yellow colour on woollen goods, when mordanted with salts of tin, to which has been added alum or cream of tartar, still its employment has greatly decreased of late years, owing to its colour assuming a reddish hue when exposed to the atmosphere.

Within the last twenty years a preparation from it has been imported into this country from America, under the name of *flavine*, which in reality may be considered as commercial quercetin. It is now manufactured in England by two different processes. The first consists in boiling half a ton of quercitron bark with sixty-three pounds of soda crystals in about 2000 gallons of water; after boiling for about a quarter of an hour, 250 pounds of concentrated oil of vitriol are added. The whole is then maintained at the boil for two hours, when it is run off on to woollen filters, washed until free from acid, pressed and dried, and is ready for market. The second process, which I consider the better one, consists in boiling for two hours 100 parts of quercitron bark with 300 of water and 15 of oil of vitriol, and then washing, pressing and drying, as in the first process. 100 parts of quercitron bark gave 85 of flavine, which have a dyeing power equal to 250 parts of quercitron.

Flavine is not much employed in calico-printing as a yellow dye, its principal use being to communicate a brown and orange hue to madder reds.

The best mode of estimating the value of a sample of quercitron bark or flavine is to dye some mordanted cloth in the same way as in testing the value of a madder or garanceine.

(*To be continued.*)

Parliamentary and Law Proceedings.

A Wrong Label.

On Monday, December 18th, an inquest was held at Southport, on the body of a child ten months old, the son of Richard Rimmer.

From the evidence of the mother it appeared that as the child had been suffering from a cold, she had sent to the shop of Mr. Barrow for a pennyworth each of oil of almonds and syrup of violets. The bottle had a new label on when it came back, and she noticed that it was different to the one it had on when sent by her. She thought the new label was "Essence of Almonds," instead of "Oil of Almonds;" but it had on the word "Poison." On account of the different label being on the bottle she put it in the cupboard, declining then to give the child the mixture, and had never given it any until Saturday night last, when she took it from the cupboard, thinking the medicine might be right and the label wrong. She intended, during the week, to take it back to the druggist, but this she neglected. When sending for the mixture for the child, she also instructed the girl to purchase her a small quantity of antimonial wine, laudanum, and essence of aniseed, for her own cough, but she never gave any of the mixture to the little one. On the previous Saturday she gave the child a teaspoonful, when it appeared to be choked, and, notwithstanding her efforts to restore it, died shortly afterwards.

Dr. Davies stated that he was called in and found the child dead. On asking the mother what she had given it she showed him a bottle labelled, "Essence of Bitter Almonds—Poison." He took the bottle home, but could find no trace of essence of bitter almonds in the contents. He had made a *post-mortem* examination, and had come to the conclusion that death arose from suffocation, caused by spasm of the glottis, produced by the improper administration of the medicine whilst the child was screaming. Such an effect might have been caused by a drop of water or saliva, more particularly by a thick substance like syrup. The bottle he found to contain oil of almonds and syrup of violets, but it was wrongly labelled.

Mr. James Barrow, chemist and druggist, 209, Lord Street, was now examined. He remembered the girl coming for the mixture, and she was carefully supplied with the drugs asked for. Unfortunately the bad divisions in the drawer allow the labels to get mixed, but the label in question was taken from the right compartment. The labels had slipped from one partition to another. He said he could mention several instances where the same medicine had been taken regularly. He examined the medicine, and found it perfectly right. It did not contain any prussic acid, or any essence of bitter almonds. The oil of almonds is quite innocuous, and there is not one instance in which it has proved dangerous. The medicine was frequently used, and there was no necessity for him to put the word "poison" on the bottle. He assured the jury that he took every possible precaution to prevent accidents, and had supplied oil of almonds out of the same bottle for some time. The key of the poison cupboard he always kept in his pocket.

The coroner, in addressing the jury, said there was not much for them to do, as he thought the death was purely accidental. The result of the entire evidence showed that there had been no mistake whatever on the part of the chemist, with the exception, of course, of labelling the bottle, and in that there had been no harm. The mistake was in the mother not giving the child the medicine properly. The chemist could not be blamed in the least, but he should show more caution in getting the labels.

The jury consequently returned a verdict of "Died through misadventure."—*Southport Independent.*

American Diplomas.

On Thursday, December 21st, at Shrewsbury, Mr. Thomas Andrews, of Keltown, was charged with an infringement of the Medical Act, by falsely assuming the title of M.D. It was proved that defendant, who had been for some years a druggist in the town, had recently sent out a bill for professional attendance, had attached M.D. to his name, and had "M.D." painted underneath his name on a lamp in front of his door.* For the defence, it was shown that defendant had received a diploma of the Medical University of Pennsylvania; and Mr. Motteram, barrister, who appeared for the defence, contended that even if the college had no power to grant the diploma, if defendant believed that it had, the charge must fall to the ground, and cited cases in support of his view. He called Mr. George Lever to swear to the authority of the diploma, which he did. Being asked to read it (it was in Latin), the witness declined to do so; and, subsequently, said that the knowledge of Greek and Latin was looked upon as a secondary consideration in the medical university alluded to. He visited the university and attended lectures; but he believed diplomas, after an examination by a duly authorized board in this country, were granted. He had no idea, however, what the nature of the examination was.

The Bench fined defendant £20; but granted, on the application of Mr. Motteram, a case for the superior Courts.

DIFFICULTIES IN DISPENSING.

Sir,—I had hoped to spend my time to-day more pleasantly, if not more profitably, than in reading and replying to the communications of your three correspondents; but, as this is pre-eminently the day of "peace and good will to man," I will accept their good will, and endeavour to forget anything that may have seemed to have an opposite tendency.

Mr. Clark objects that in my paper I did not "assert the principle that the prescriber should be communicated with where possible." I did not for the very obvious reason that the subject of my paper not being "mistakes in prescribing," but "difficulties in dispensing," that question was not within its scope; and also because I considered the principle to be so generally acknowledged, I really did not think any allusion to it necessary.

Next, with regard to the disputed question of an excessive quantity of essential oils in pills, I think there can be no doubt that they are frequently ordered at random, without the prescriber having the least idea that the quantity prescribed cannot be got in by fair means; and, being very often merely flavouring ingredients, it does not weigh very heavily on my conscience to leave out the excess, rather than to increase the bulk of the pill by the addition of tragacanth, or to alter its chemical constitution by the addition of magnesia; and I think we ought to be quite as mindful what we add as what we subtract. Let it, however, be clearly understood that I protest as strongly as any one against any omission of, or tampering with, any active or really important ingredient.

With regard to the more personal part of this controversy, if I have said anything to wound the feelings of any one, I am sorry to have done so. I never like to see personalities introduced into a discussion of this nature, but think that we ought always to try and give people credit for good intentions at least, and not too hastily condemn in strong terms what we do not altogether approve of, remembering there may be something we know not of that may give a totally different complexion to the matter. I believe we are all agreed that the intentions of the prescriber should be carried out as far as possible, though we may differ somewhat as to the mode of doing so.

W. WILKINSON.

Cheetham Hill, Dec. 25th, 1871.

SYRUP OF TOLU.

Sir,—Many of your readers may be glad to know of another use to which the waste resin of the syr. tolu process may be put. As Mr. Haselden has observed, the balsam of tolu is not exhausted by the boiling with water in such quantity as is directed by the Pharmacopœia, and I have used the residue for benzoating fats used in the preparation of pomades, etc., with very good results. Lard, etc., is thus preserved from rancidity, and the citrine perfumes are in great measure preserved from change; besides which, the odour of the balsam communicated to the pomade forms a good basis for the perfume.

24, *High Street, Strood,* J. KNOWLES.
December 14th, 1871.

P.S.—It communicates a slight greenish colour to colourless fat.

Sir,—A difference of opinion seems to exist as to the proper method of preparing this adjunct to "elegant pharmacy." Mr. Haselden states that if the liquid be filtered whilst hot, the syrup would contain resinous matter and cinnamic acid "which might induce, and has been known to do so, the very irritation or tickling about the fauces which it was intended to allay." It will occur to any practical chemist and druggist that the ordinary syrup of balsam (formerly Syr. Tolutani, Ph. Lond.) is made by adding about ℥j Tr. Tolu to 2 simple syrup, which remedy is much in request for the tickling cough of infancy; here is an undoubted combination of all the constituents of balsam of tolu; and it is hard to understand on the above quoted theory, how any good can result from its use, unless we adopt the motto, "Similia similibus." (See also United States Pharmacopœia.)

Again, aged people (some who have even reached their second childhood) believe very much in the efficacy of Friar's balsam, which, in addition to balsam of tolu, also contains benzoin and storax, both rich in the same principles.

It does not seem possible that a clear syrup could be made if resinous and insoluble matters are suspended in it; what we prepare is uniformly bright and limpid. The matter may seem in itself trifling, but it is scarcely worth while adding to the time required for making a preparation which occupies quite enough of that valuable article, let it be done ever so expeditiously.

R. Goodwin Mumbray.

Richmond, December 18th, 1871.

Professor Tyndall's Theory of the Blue Colour of the Sky.

Sir,—In answer to your correspondent Dr. Barnsley, of Barra Mansa, Rio de Janeiro, I would say that he appears to have allowed his ideas to be more or less confused by failing sufficiently to discriminate between the various modes of the conveyance of light known as "reflected," "transmitted" and "scattered" light, of which I am sure he will require no explanation at my hands.

Replying to his first question,—no sunbeam, under spectral analysis, has been found without the blue waves. In looking directly at the sun the impression of colour is yellow or reddish-yellow. The blue is also there; but so weakened in intensity as to be almost entirely overpowered in our perception by the other constituents of the solar rays.

In answer to the second question,—Dr. Barnsley takes the term "stopped" in a sense different to that which was intended by me. What I meant was, that the blue waves, on coming in contact with the particles, are not only stopped, but immediately scattered in all directions and reach our retinæ, therefore, at all angles, producing a blue impression.

Replying to Dr. Barnsley's third question,—I must refer him to my answer to his first two questions, depending as it does on the meaning I intended to convey by the word "stopped."

Dr. Barnsley's remark, "that on the highest mountains the sky is of an inky hue," is borne out by several authorities, among them Mr. T. G. Bonney, who ascended Monte Rosa, 15,217 feet above the sea-level, and who states that "the colour was so deep as almost to approach black. This intensity of colour was only very conspicuous during the last few hundred feet of the ascent."

Mr. Hincliff, in his 'Summer Months among the Alps,' corroborates this statement of Mr. Bonney. These facts, I think, strengthen the theory of Professor Tyndall. The atmosphere at such heights is more rarified, and, therefore, more free from large particles than it would be nearer the earth. It is these large particles which diminish the intensity of the blue impression on our vision, by scattering more of the larger waves (namely, the red and yellow) into space, in addition to the blue ones.

In answer to your correspondent's fifth question,—it cannot be proved, experimentally, that "our atmosphere is filled with countless millions of excessively minute particles;" but Professor Tyndall does not go further than to point out that all "the phenomena certainly occur, as if our atmosphere were a medium, rendered slightly turbid by the mechanical suspension of exceedingly small foreign particles," and that they would not be satisfactorily accounted for on any other supposition but this. Again, by producing, artificially, a similar condition of matter supposed by this theory, we get the same results as we offer to explain, which, to my mind, is almost conclusive proof of its probable correctness.

With regard to my experiment, Dr. Barnsley's supposition of the position of my apparatus is directly contrary to the facts. My magnesium lamp was placed at the side of the glass vessel containing the suspended particles of gum, and the light from the latter, seen by myself and my audience, was entirely reflected, and we therefore saw blue. Had the vessel been, as Dr. Barnsley remarks, "between the light and the retina," his view would be quite correct, as the colour produced in this position was, as Dr. Barnsley states, "a compound of the prismatic colours, minus the blue."

Apologizing for the delay in replying, I have the honour to remain,

Albert Henry Samuel.

145, *Upper Parliament Street, Liverpool, December 4th,* 1871.

Early Closing.

Sir,—Seeing that almost every trade, with the exception of the druggists, are making endeavours to shorten their business hours, I think it is time we took it to heart and tried if we cannot get our long period of daily labour shortened, and thus afford both to employers and employed a chance of enjoyment and recreation. No wonder we poor druggists, as a majority, look pale and wan, when we are behind a counter or in a stinking warehouse or laboratory from 7.30 A.M. to 10 P.M.

This is the way to ruin a man's health. How can an apprentice be expected to study after ten at night? He wants to go to bed then, independent of never having any out-door recreation. "All work and no play makes a dull boy." So let us take more recreation, and we shall be able to work all the harder and better at the proper time.

I hope some one may take the matter up as well as myself, as I dare say many others are so situated.

W. S. Stables.

The Preliminary Examination.

Sir,—I have read several letters lately respecting the mode of conducting the Preliminary examination, and from the fact that it is merely an educational test, consider that it would give far more satisfaction to the trade at large, as well as the candidates, if it were conducted by the College of Preceptors; they have, I believe, conducted the Preliminary at the College of Surgeons for some time.

TWO MEDICINAL BARKS FROM CEYLON.

BY M. C. COOKE, M.A.

Samadera Bark, *Samadera indica*, Gærtn. Having received specimens of this drug through the kindness of M. P. J. Ondaatje, Esq., of Ceylon, now resident in London, we proceed to give a few particulars of what will doubtless prove to be a very valuable addition to the list of Oriental materia medica. The drug consists of a thin fibrous inner bark, almost of a primrose yellow, and not thicker than stout cartridge paper. It is in irregular fragments, from two or three to seven or eight inches in length, and from half an inch to upwards of an inch in breadth, fibrous when broken, and though readily splitting in a longitudinal direction, is tough transversely. When masticated it has an intense, though by no means unpleasant, bitter taste,—not unlike that of quassia, but more intensified; in fact, its intensity seemed to us greater than that of any drug of its kind with which we are acquainted. One is led to inquire, how it is that a substance which appeals so immediately to the senses should for so long have been comparatively unknown. Of course, we have had no opportunity of practically testing its merits, but its own recommendation is so strong, combined with the fact that the tree which yields it belongs to the Natural Order *Simarubaceæ*, in common with *Simaruba* and *Quassia*, that we are disposed to regard it as fully equal to the best of either, and it may be superior when subjected to a fair trial.

The following is a brief description of the tree which yields the Samadera bark:—

A tree of from thirty to thirty-five feet in height. Leaves alternate, oblong elliptical, very long; calycine segments 4–5 each, marked with an external gland; petals 5, longer than the calyx; flower-bearing peduncles longer than the leaves, pendulous, compressed axillary or terminal, divided at the apex into a small umbel; drupe with a thick pericarp, somewhat angled; flowers white (Wight's *Illustrations*, plate 68). Ceylon, Cochin and Malabar; flowering in the hot season. It grows abundantly in Travancore, and is easily propagated from seeds. Drury says of it, that the bark has febrifugal properties, and is used by the natives of India for this purpose. An oil is extracted from the kernels of the fruit, which is extensively used in rheumatism on the West Coast, and is procurable in the bazaars. In erysipelas the leaves bruised are applied externally. Their juice boiled up with oil is given as a liniment in psydracia.

The tree is known in South-western India by the name of "Karinghota," and in Ceylon as "Samadera-gass."* In Thwaites' 'Ceylon Plants' it is stated that "the root of this plant is used as a medicine by the Cinghalese, and so also is the fruit;" but nothing is mentioned about the intense bitterness of the inner bark, or its medicinal uses. If it is really plentiful in Southern India and Ceylon, trials should be made of the bark, both in those places and here, since a substance of so much promise should not be neglected for want of the necessary experiments. Because so many Eastern drugs have proved to be comparatively worthless, there is no reason why others may not prove exceedingly valuable.

Kokoon Bark, *Kokoona zeylanica*, Thw. Mr. Ondaatje has also favoured us with this product, and informs us that the inner yellow bark of the kokoon-tree of Ceylon is employed as a febrifuge and sternutatory, and as a dye. In Thwaites' 'Ceylon Plants' it is stated that "the inner yellow bark of this tree is employed by the natives medicinally as a sternutatory, and an oil is expressed from the seeds, which is used for burning in lamps" (p. 52).

The tree belongs to the Natural Order *Hippocrateaceæ*, and the species is described by Thwaites in Hooker's 'Journal of Botany,' vol. v. (1853) p. 379, accompanied by a plate.

It is a large forest tree, sixty feet or upwards in height, much branched, especially towards the top. Bark rough, when cut of a yellow colour, somewhat corky. Leaves dark green, smooth, underneath paler, with very numerous minute, dark red, glandular dots. Stipules very minute, deep red, subpersistent. Panicles axillary, raceme-like. Bracts very minute, acute. Flowers dull yellowish-brown. Calyx minute, with five shallow lobes, persistent. Petals five, concave, firm in texture with minute pale glandular dots on the inner surface, twisted in æstivation. Stamens five, alternate with the petals, inserted into depressions of the dark green angular disc. Ovary three-celled, each cell with four ascending anatropal ovules. Style short. Stigma capitate, somewhat three-lobed. Capsule 1–4 inches long, oblong bluntly triangular, three-valved, three-celled. Seeds imbricated, winged, erect, exalbuminous. Wing very broad, oblong, truncate or blunt. Embryo orthotropal; cotyledons flat.—Hook. Journ. 1853, p. 380, pl. 6.

Not uncommon on the banks of streams in the Suffragam and Ambagamowa districts, at an elevation of 2000 to 4000 feet. Native name "kokoon-gass."

The yellow bark is sold in the bazaars, and when pounded is used by the Cinghalese as a kind of cephalic snuff, being mixed with ghee and introduced into the nostrils, in order to relieve severe headache, by encouraging a copious secretion from the nose. (Thwaites.)

The bazaar drug consists of small fragments of the bark, the largest not exceeding an inch in length, but the majority not more than a quarter of an inch; of a bright ochraceous or dull orange colour when broken, very friable, and easily reduced to powder, which plentifully accompanies the bark, as also do portions of the capsules. There is scarcely any perceptible odour or taste. In the fragments of bark from young branches there is at length a slight bitterness after mastication. The value of the drug as a febrifuge appears to be very doubtful, and we have no information as to the success attending its employment by Mr. Ondaatje himself.

* *Gass*, in the Cinghalese language, signifies *tree*.

PURE BROMIDE OF POTASSIUM.*

BY M. FALIÈRES.

The employment of bromide of potassium in affections of the nervous system has become so general during the last few years as to create for it a considerable demand. This has resulted in much competition among those engaged in the manufacture and

* From a Report made by MM. Poggiale and Gobley to the Academy of Medicine upon a Memoir by M. Falières, entitled "Monographie Chimique et Pharmaceutique du Bromure de Potassium" (Journ. Pharm. [4] xiv. 247).

the accompaniment of frauds, so frequently encountered in connection with high-priced products. It is important, therefore, that pharmaceutists should be acquainted with the means of exposing these falsifications, so that they may be able to supply to their customers a pure bromide of potassium; and to this part of the subject M. Falières devotes the first part of his monograph.

Among the salts that have been detected in commercial bromide of potassium are iodide of potassium, chloride of potassium, potash in a free and carbonated state, sulphate of potash, nitrate of soda and bromate of potash. Considering its high price, it is not probable that iodide of potassium is fraudulently introduced into the bromide; but its presence is probably due to the fact, that the bromine of commerce usually contains traces of iodine. Small quantities of iodine may be detected by treating a solution of the bromide of potassium with chlorine water or bromine water. The iodine which is set free gives a blue colour with the mucilage of starch, and rose or amethyst violet with benzine, chloroform or sulphide of carbon. But M. Falières gives the preference to a process employed by M. Bouis to detect iodine in mineral waters. It consists in introducing some solution of the bromide of potassium under examination into a small closed tube, then adding a few drops of solution of perchloride of iron and boiling the mixture. The perchloride of iron is without action upon the bromide of potassium, while it completely precipitates the iodine from the iodide. Consequently, if a piece of starched paper be introduced into the tube, the blue tint of iodide of starch appears if the solution contains only traces of iodine; but it is a better plan to distil a small quantity of the solution and seek for the iodine in the distillate. M. Falières proposes to make this method more practical still, by simply dipping a small slip of ordinary white paper into the solution containing the bromide of potassium and perchloride of iron, when, if the liquor contains iodine, the paper will become blue.

M. Falières has noticed in bromide of potassium the presence of quantities, often considerable, of chloride of potassium. M. Adrian, also, has ascertained that of ten specimens obtained from the principal manufactories for the supply of pharmacy, one only was suitable for employment in medicine. In the other nine he found variable quantities of the chloride, amounting sometimes to 30 per cent. of the entire weight. He has remarked besides, that one of the most beautiful specimens, judging by the regularity of the crystals, was also one of the most impure. This fraud is a very grave one, as it cannot be doubted that it interferes seriously with the therapeutical action of the bromide, and it is important, therefore, that pharmaceutists should be able to determine in a precise manner the proportion of the chloride; but the estimation is one that presents great difficulties.

It is well known that chlorine, bromine and iodine, and their compounds, present such close analogies that no good process has yet been discovered for their separation. Of chlorine and bromine particularly, the solubility and insolubility of the combinations which they form are so nearly alike that it is very difficult to accomplish their separation by means of an insoluble precipitate. The application of the numerous gravimetric methods presents so many difficulties, that the analysis of a mixture of chlorine and bromine, and even of iodine, is doubtless one of the most delicate of operations, requiring great skill in the manipulation.

In 1868, M. Baudrimont published* what he termed the "indirect process" for the detection of the presence of chloride in commercial bromide of potassium. It was based upon a fact well known to chemists, that a given weight of chloride of potassium decomposes a much larger proportion of a titrated solution of nitrate of silver than the same weight of bromide of potassium. For instance, 1 gram of the bromide requires for its complete precipitation as bromide of silver only 1·427 gram of the nitrate of silver, whilst it requires 2·279 grams of the same nitrate to entirely convert one gram of chloride of potassium into chloride of silver.

In February, 1869, M. Falières communicated to the Société de Pharmacie at Bordeaux a process of volumetric analysis for a mixture of chloride and bromide of potassium by means of a titrated solution of nitrate of silver,—an idea which he then thought to be entirely new, but for which he afterwards yielded the palm of priority to M. Baudrimont. But the process of M. Falières constitutes a considerable advance, and will be very useful in ascertaining the degree of purity of bromide of potassium. Taking advantage of the recognized fact that the before-mentioned proportions of nitrate of silver are required for the conversion of bromide and chloride of potassium into bromide and chloride of silver respectively, M. Falières points out that in a mixture of ·9 of bromide and ·1 of chloride, the quantity of nitrate of silver requisite for their complete conversion would be—

$$1{\cdot}427 \times 0{\cdot}9 + 2{\cdot}279 \times 0{\cdot}1 = 1{\cdot}5122.$$

Consequently, if the bromide contains 10 per cent. of chloride, it would be necessary, after having treated the mixture with 1·427 of the nitrate of silver, still to add 0·0852 of the same reagent. It is evident, therefore, says M. Falières, that if ·852 of nitrate of silver be dissolved in 100 cubic centimetres of distilled water, and after having treated 1·0 of bromide of potassium with 1·427 of silver, it still requires for complete precipitation 5, 10, 20 or 30 cubic centimetres of the titrated solution, it is because the bromide of potassium under analysis contains 5, 10, 20 or 30 per cent. of chloride.

The details of the process, as given by M. Falières, are as follows:—First, it is necessary to ensure—by means of perchloride of iron, salts of baryta and strong sulphuric acid in excess—that there are no other salts present, such as iodide of potassium, carbonate and sulphate of potash, or nitrate of soda, which would disturb the results of the analysis. Then dissolve, in a stoppered bottle, 1 gram of the bromide of potassium in 30 or 40 grams of water, and add a solution containing 1·427 gram of nitrate of silver. When the precipitate has settled to the bottom of the bottle, add the bromometric liquor drop by drop by means of a Gay-Lussac burette. If the bromide be pure, the addition of a drop of this liquid will cause no turbidity; if, on the contrary, a precipitate is formed, the volume of the test liquor employed will show the quantity of chloride present. This operation is reported to be easily performed, and to yield good results.

* *Journal de Pharmacie et de Chimie*, vii. 411.

M. Falières next indicates the proper method for ascertaining the presence of potash, carbonate of potash, bromate of potash, sulphate of potash and nitrate of soda.

Upon a small piece of iodine being thrown into a solution of bromide of potassium the liquor will assume a yellow tinge if the bromide be neutral, but it will remain uncoloured if it contain potash or carbonate of potash. The latter salt may be detected by means of lime or salts of baryta; the precipitate is soluble with effervescence in acids. The presence of bromate of potash may be detected by heating some of the solution with colourless hydrochloric acid. The solution takes a yellow tinge if it contains bromate of potash, but remains colourless if the bromide be pure.

M. Falières states that he has found nitrate of soda in many specimens of bromide of potassium of English manufacture. This fraud occupied his particular attention in consequence of the difficulty of its detection. As nitrate of silver exercises no action upon nitrate of soda, its presence might be unsuspected unless it were specially sought for. When a mixture of bromide of potassium and nitrate of soda is treated with strong sulphuric acid in excess, hydrobromic acid and ruddy vapours of bromine and hyponitric acid are formed. If the bromide of potassium be pure, white vapour of hydrobromic acid is abundantly disengaged, and a small quantity of reddish-yellow vapour of bromine. M. Falières thinks that these reactions would be sufficiently distinct; but the gentlemen who reported on the memoir to the Academy consider that when the quantity of nitrate of soda is small, the result would not be clear. They recommend that in that case the nitric acid should be estimated by one of the known volumetric methods, and the bromine by a titrated solution of nitrate of silver.

The second part of the memoir is devoted to discussion of the best mode of preparing pure bromide of potassium. If the ordinary manufacturing process of preparing bromine from the mother liquors of soda is considered, together with the composition of caustic potash, it will be seen how easily the bromide of potassium prepared from them may become contaminated by the salts already noticed. M. Falières therefore turned his attention to discovering a means of obtaining bromine and potash completely pure for the purpose. The elimination of iodine from bromide of potassium may be easily accomplished by the process of M. Baudrimont, which consists in boiling the iodized bromide with an excess of bromine water, when the iodine that is driven off by ebullition is replaced by the bromine. The liquor is afterwards evaporated to dryness, to drive off excess of bromine.

The process recommended for the purification of bromine is based upon the following reaction. If a solution of bromide of potassium be poured into a saturated aqueous solution of chloride of bromine, the mixture becomes turbid, and pure bromine is thrown down; and if the mixture be heated to drive off excess of bromine and of chlorine, the supernatant liquor will contain only chloride of potassium, the bromine of the chloride of bromine and the alkaline bromide being set free and deposited. Consequently, if commercial bromine be treated with a slight excess of bromide of potassium, the bromine will be deprived of any chlorine it may contain. Such salts as nitrates, bromates, sulphates and chlorides will remain in solution; but any iodine that may be present will be precipitated with the bromine; from which it may be easily purified by the process before mentioned.

Potash alcohol being too expensive, and caustic potash always containing foreign matters, M. Falières proposes to employ purified bicarbonate of potash in the preparation of bromide of potassium. 100 grams of the bicarbonate are dissolved in 500 grams of distilled water, to which is added 80 grams of pure bromine. When the disengagement of carbonic acid has ceased, a solution, composed of 90 parts of water and 30 parts of ammonia, sp. gr. ·875, is poured in. It is then evaporated to dryness, and the residue heated until white ammoniacal vapours are no longer given off. The salt is then fused, in order to convert the bromate into bromide. The product is redissolved in bromine water, evaporated and set aside to crystallize. It is important to notice that in this process the bromide of ammonium reacts upon the undecomposed carbonate of potash and converts it into carbonate of ammonia, which is volatilized. The bromate so obtained does not appear to contain the least trace of carbonate.

M. Castelhaz, who has proposed to replace in medical practice the bromide of potassium by that of sodium, prepares the latter by an analogous process, treating the bromide of ammonium by an equivalent quantity of pure soda or carbonate of soda. He obtains the pure bromide of ammonium by letting bromine fall drop by drop into ammonia diluted by distilled water, and conducting the operation in a Woulfe's apparatus, in order to avoid loss. The evaporation is accomplished in an iron retort, and the disengaged vapours collected in a stone-ware receiver. The decomposition of the bromide of ammonium by the carbonate of soda is also carried on in an iron retort communicating with two large vessels for the condensation of the vapours.

TRANSFORMATION OF A SOLUTION OF CANE-SUGAR INTO GLUCOSE UNDER THE INFLUENCE OF LIGHT.

BY M. E. M. RAOULT.

The author, in a short note presented to the Académie des Sciences,* says that the idea that a solution of cane-sugar, kept at the ordinary temperature, and protected from the action of ferments, will preserve indefinitely its flavour and chemical properties, is an error. He states that he has often observed such a solution, without undergoing the least fermentation, to become altered, and at length transformed, more or less completely, into glucose; and during the present year he has made the following experiment, which shows that this change takes place under the influence of light:—

On the 12th of May, 10 grams of white sugar were dissolved in 50 grams of pure water. Equal volumes of this solution being introduced into two tubes of white glass were boiled for some minutes, and the tubes closed at a flame before the re-entry of air. The tubes so prepared were placed, one in complete darkness, the other in a good light; but, at the same time, they were kept side by side, that they might be subjected to the same variations of tempe-

* Comptes Rendus, vol. lxxiii. p. 1049.

rature. Five months afterwards, the 20th of October, the tubes were opened. The solutions were perfectly transparent, and contained no microscopic vegetation. That which had been kept in darkness gave no reaction with the cupro-potassic test of M. Barreswil, thus showing that it contained no glucose. When that reagent, however, was added to the solution which had been exposed to the light, it caused an abundant red precipitate. About half the cane-sugar at first contained in the solution was found to have changed; so that under the influence of light, cane-sugar dissolved in water changes slowly into glucose.

It results from this that a syrup might contain a considerable quantity of glucose, although cane-sugar only had been used in its manufacture, and that such an occurrence is not necessarily evidence of an adulteration.

At a subsequent sitting of the Academy,* a note was read relative to this subject, from M. Maumené, in which that gentleman stated that he had many years since indicated the possibility of the slow transformation of cane-sugar into glucose without the intervention of a ferment.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Potassæ Nitras, KNO_3.—Exists ready-formed in the juices of many plants, and sometimes appears as an efflorescence upon the surface of extracts. It is also a common constituent of well and river waters. It is, however, always obtained from the earth, being found in various districts in the East Indies as a saline crust or deposit upon or near the surface of the soil. It is simply dissolved out, and, to purify it, is recrystallized several times. It is also made artificially by exposing a damp mixture of nitrogenous organic refuse and lime or wood ashes to the air.

[§ In white crystalline masses or fragments of striated six-sided prisms.] It is anhydrous, and therefore unlike sulphate of sodium; for example, it does not effloresce. [§ Thrown on the fire it deflagrates; warmed in a test-tube with sulphuric acid and copper-wire, it evolves ruddy fumes.] It should be free from chloride and sulphate.

Fused and moulded, it forms sal-prunella. Heated more strongly it loses a portion of its oxygen, leaving, if it be stopped at the right point, potassic nitrite, KNO_2, or ultimately a mixture of the oxides of potassium K_2O and K_2O_2. In the fused state it is often employed as an agent of oxidation, as, for example, in making arseniate of sodium.

Potassæ Permanganas, $K_2Mn_2O_8$.—Is always produced by the decomposition of the manganate, K_2MnO_4.

The manganate of sodium is made on the large scale by exposing to a dull red heat for many hours a mixture of caustic soda and peroxide of manganese: oxygen is absorbed from the air.

$$2NaHO + MnO_2 + O = Na_2MnO_4 + H_2O.$$

According to the Pharmacopœia, which adopts the usual method, a mixture of caustic potash and manganese oxide acquires the necessary oxygen by fusion with chlorate of potassium.

$$3(2KHO + MnO_2) + KClO_3 = 3(K_2MnO_4 + H_2O) + KCl.$$

The heat must be carefully applied, or the product will be decomposed. A scarcely visible heat for about twenty minutes is sufficient for a small quantity. The green mass, boiled in water, yields a green solution, which is strongly alkaline. This is mixed with dilute sulphuric acid till the colour changes to bright purple, is evaporated quickly, decanted from the deposited peroxide of manganese, and set to crystallize. Chlorine or carbonic acid gas passed into the solution is better than sulphuric acid for the transformation of manganate into permanganate. In either case the change is simply due to the abstraction of half the potassium, but when the acid is employed, one-third of the manganese is precipitated as peroxide.

$$\underbrace{3K_2MnO_4}_{\text{Manganate.}} + 2H_2SO_4$$

$$\text{Or } 2K_2MnO_4 + K_2O\,.\,MnO_2\,.\,O + 2H_2SO_4$$
$$= \underbrace{K_2Mn_2O_8}_{\text{Permanganate.}} + \underbrace{MnO_2}_{\text{Peroxide of Manganese.}} + \underbrace{2K_2SO_4}_{\text{Sulphate of Potassium.}} + \underbrace{2H_2O.}_{\text{Water.}}$$

When chlorine is employed—

$$\underbrace{2K_2MnO_4}_{\text{Manganate.}} + Cl_2 = \underbrace{K_2Mn_2O_8}_{\text{Permanganate.}} + 2KCl.$$

The solutions cannot be filtered.

The salt is easily recognized when in the solid form by the purplish semi-metallic lustre of the crystals, and by the intensely purple solution which they yield.

It must not be forgotten that the salt is decomposed, and its colour destroyed, with formation of a brown deposit of peroxide of manganese, by organic matters of every kind. Tinctures, infusions and vegetable preparations are therefore incompatible with it, as are also such things as glycerine, sulphate of iron, sulphurous acid, essential oils, and many others.

CHROMIC ACID AS AN ANTISEPTIC, DISINFECTANT, ETC.,

More Especially as Compared with Carbolic Acid.*

BY JOHN DOUGALL, M.D. GLAS.

Chromic acid occurs in brilliant crimson needles, which deliquesce by exposure to the air. When pure it is almost odourless. Its aqueous solution has a sour metallic taste, and a rich amber or reddish-brown colour. It is very soluble in water, sparingly soluble in chloroform, insoluble in the fixed oils and fats. Contact with carbolic acid, mucilage, glycerine, alcohol, ether, and with organic matter generally, instantly decomposes it with more or less violence, oxygen being evolved and heat generated.

Antiseptic properties.—As an antiseptic, disinfectant, and preventive of germ growth, chromic acid stands "second to none." Several varied experiments were made in order to ascertain its antiseptic powers in contrast with those of carbolic acid. One detailed may suffice, all the others confirming it. One ounce of ox muscle was immersed for twenty-four hours in four ounces of an aqueous solution of chromic acid (1–2000), then suspended in air. In two days it was quite black, and in six days as hard as wood, in which condition it

* Reprinted from the *Lancet*, vol. ii. (1871) p. 847.

still remains (three months after), without mould or taint. One ounce of ox muscle was immersed for twenty-hours in four ounces of an aqueous solution of carbolic acid (1–1000), then suspended in air. In six days it was much hardened, brownish-black, speckled with mould, and distinctly tainted.

It appears that chromic acid acts as an antiseptic by coagulating protean compounds, a property which it possesses in the highest degree, and to which I am not aware that attention has been hitherto directed, although used for a considerable time in hardening animal tissues for microscopical examination. The coagulating power of chromic acid in albuminous solutions has been compared with that of most metallic salts, various acids, etc., and found to exceed them all: *e. g.* it has about ten times the coagulating power of carbolic acid, fifteen times that of nitric acid, twenty times that of bichloride of mercury, and a hundred and fifty times that of chlor-alum, etc. Shortly after a piece of muscle is immersed in a solution of chromic acid, there forms in considerable quantity a greyish, opaque, granular sediment, coagulated albumen; while the deep red of the muscle is changed to brownish-yellow, ultimately it looks as if it had been boiled, the residual portion of muscle being composed almost exclusively of fibrous stroma, and becoming, on drying, extremely hard and tough. A portion of muscle immersed in a solution of carbolic acid retains a light pinkish, somewhat blanched aspect; while the solution, remaining void of sediment, is reddish and hazy, but translucent. If to a portion of this fluid there be added a little chromic acid solution, not stronger than 1-1000, a voluminous precipitate of albumen is at once obtained, clearly demonstrating the superior coagulating power of chromic acid over that of carbolic acid.

A solution of two grains per ounce at once indicates the presence of albumen in a solution consisting of one part of a saturated solution of beef juice in twenty of water; while one of beef juice in thirty of water may be detected by allowing the mixture to stand for twelve hours. Chromic acid is admirably adapted for determining volumetrically the percentage of albumen in a fluid. An albumenometer may be constructed as follows: Fill a wide-mouthed burette to a multiple of 100 with albuminous urine or an albuminous fluid; add solution of chromic acid, about four grains per ounce, in slight excess; shake the mixture; set aside for twenty-four hours; read off the precipitate, and multiply to per cent. No heating is required. Chromic acid also coagulates mucus, saliva, chondrin, and gelatine. With the latter two it forms, in excess, canary-yellow fluids and flocculent precipitates coloured like chromate of lead. The reaction with gelatine is as delicate as that with tannin, giving a response with 1 to 5000. Chromic acid is therefore a test for gelatine. An aqueous solution of carbolic acid (1 to 20) produces only slight haziness in gelatinous solutions.

Disinfecting properties. — Chromic acid coagulates, hardens, and oxidizes decomposing organic matter. It combines simultaneously with ammoniacal products and with nascent sulphuretted hydrogen, reducing the latter to water and free sulphur ($2CrO_3 \times 3H_2S = Cr_2O_3 \times 3H_2O + 3S$). Added to putrid blood, flesh, pus, urine, or fæcal matter, the offensive odour is soon absolutely removed, the mixture remaining fresh for an indefinite time. Dr. R. A. Smith found that bichromate of potassium surpassed thirteen other of the most energetic antiseptics, including carbolic acid, in preventing the evolution of sulphuretted hydrogen in a mixture of equal parts of blood and water.* This salt has a coagulating power near that of nitric acid; *i. e.* fifteen times weaker than that of chromie acid. Hoppe Seyler has shown that, "while in disinfection it is highly necessary to destroy the products of fermentation and putrefaction, yet the destruction of sulphuretted hydrogen and ammonia can have no more influence on the fermentative changes involved in cholera and typhus than the removal of carbonic acid can have upon the progress of alcoholic fermentation; and therefore the ferment itself must be attacked, which, as pointed out, is more resistent than the living organisms in decomposing solutions."* Now chromic acid, as already shown, fulfils admirably these requirements. Carbolic acid does not combine with ammonia, nor decompose sulphuretted hydrogen. This is surely of importance in a sanitary sense, when it is remembered that almost to these properties alone are due the marked disinfecting powers of sulphurous acid, nitrous acid, permanganate of potassium, bisulphite of lime, protosulphate of iron, chloride of zinc, chloride of aluminium, chlorine, bromine, iodine, etc. Carbolic acid seems to act as an antiseptic solely by coagulating albumen. It does not preserve by absorbing and retaining moisture, like chloride of sodium, alcohol, etc., as, practically, it has no affinity for water. Chromic acid is the reverse.

In Dr. A. E. Sansom's book, page 28,† the following passage occurs:—"It has been shown, however, that carbolic acid has the faculty of coagulating albumen. Is it on account of this faculty that it prevents fermentation and putrefaction? On this point a comparative experiment throws some light. Let a solution of the albumen of egg be precipitated, in one case by heat or by an ordinary chemical reagent, and in the other by a solution of carbolic acid, and let the resultant precipitate be kept a considerable time in contact with the air. It will be observed that whereas in the one case the albumen will become decomposed in the ordinary manner, that precipitated by the carbolic acid entirely resists putrefactive change. It is therefore obvious that carbolic acid has an action over and above its action as a mere precipitant of albumen." The fact is here ignored that in general chemical precipitates of albumen are soluble in water, specially carbolico-albuminoid precipitates; and as the latter cannot exist without the presence of carbolic acid, the difference between the "carbolic" and "heat" precipitates is simply that the one contains an antiseptic, while the other does not. As regards the other precipitates, the alleged results only show that carbolic acid is a more powerful antiseptic than any of the ordinary chemical reagents referred to. Furthermore, it may be urged that carbolic acid is volatile, whereas chromic acid is fixed; therefore the former can arrest putrefaction by coagulating floating particles of organic débris. But in a series of experiments by Dr. R. A. Smith,‡ "to determine the efficiency of strong gases and volatile substances in preventing putrefaction," it is shown that pieces of fresh meat suspended in bottles containing chlorine, bromine, iodine, hydrochloric acid, ammonia, protoxide of nitrogen, nitrous acid, and sulphurous acid, were fresh at the end of twenty-eight days; while a piece suspended in a bottle containing heavy oil of tar, and a piece in a bottle containing M'Dougall's powder, of which the chief ingredient is crude carbolic acid, grew slimy and putrid in seven days. I have also made the following experiment:—A piece of ox muscle, a portion of beef juice, of urine, and of infusion of hay, the three latter in separate phials, were suspended in a gallon bottle, which contained fully a pound of pure carbolic acid, about six inches from its surface. The bottle was kept open at about 60° F. On the fourth day the beef juice was putrid and swarming with bacteria, vibriones, etc. A portion of the same juice exposed to the air was not more putrid on the fourth day than that in the bottle. On the fifth day both the urine and infusion of hay teemed with life; while on the surface of the latter there was an abundant development of penicillium. On the sixth day the piece of muscle was putrid and slimy.

† The 'Antiseptic System'. By A. E. Sansom, M.D. Lond.

‡ 'Disinfectants and Disinfection,' p. 109.

These facts prove that the vapour of carbolic acid, even when most concentrated, fails to arrest putrefaction, and to prevent the appearance of germs; indeed, as seen with the beef juice, it does not even delay those phenomena, the portion suspended in the carbolized atmosphere putrefying as quickly as that kept in ordinary air. "Here is a beautiful hypothesis slain by an ugly fact." After these results it is impossible to conceive, as it would be absurd to expect, the infinitely minute quantity of carbolic vapour which can be tolerated in the wards of a hospital, or is capable of diffusing spontaneously in an alleged infected medium, competent to destroy floating unseen germs and organic particles, seeing that in the highest state of concentration, and all the conditions in its favour, it failed to affect visible germs and tangible organic particles.*

(*To be continued.*)

THE ODOURS OF PLANTS.†

BY JAMES BRITTEN.

The subject of the phenomena of odour and colour in plants, and of the causes which induce or govern them, is one of considerable interest; and the relations which exist between the two are sufficiently striking. Thus, it has been statistically ascertained, and a very little reflection will confirm the conclusion, that white flowers stand highest in number among fragrant species, next yellow, then red, and lastly, blue. And it is among white flowers that disagreeable odours are most seldom found, while orange and brown are frequently unpleasant in scent. In such calculations, however, it must be remembered that the appreciation of odours is by no means the same to different people: scents which are agreeable to one, are often the reverse to another. The strong odour of *Tagetes patula* and *T. erecta* is not objectionable to some; while others, besides the well-known fox-hunter, are of opinion that the Sweet Violet is a "stinking flower." There are even some unhappy beings—we trust they are but few—who cannot endure the scent of a rose. The sense of smell, too, is much more acute in some persons than in others; and we have frequently remarked an analogy to colour-blindness in the want of perception of odours manifested by some among our friends.

A good summary and comparison of scents will be found in M. Lecoq's 'Études sur la Géographie Botanique de l'Europe,' from which some of the following details are borrowed. In almost every case, however, additional instances of similarity will suggest themselves to the reader, especially if he be gifted with a keen nose, and a good memory for smells. In the first place, it may be laid down as a general principle, that a larger proportion of white flowers are fragrant than those of any other colour; yellow come next, then red, and lastly blue; after which, and in the same order, may be reckoned violet, green, orange, brown, and black.

Among white flowers, certain types of scent are very prevalent. Thus many Umbelliferous plants have a strong odour of honey, which is very marked in *Anthriscus sylvestris*, and is found also in the aquatic ranunculi: *Eucalyptus glandulosa* recalls the same scent; and in the almond and apricot we encounter it, qualified by that flavour of prussic acid which is so perceptible in the hawthorn when one does not inhale too closely the fragrance of its flowers. This scent is intensified in *Spiræa Ulmaria;* in *S. Filipendula* it is modified by a *soupçon* of the odour which is found also in the privet and in *Actæa spicata*, and attains distinctness in the elder. Many Rubiaceous shrubs have similar odours, and resemble certain *Apocyneæ;* and the *Philadelphus coronarius* has so much affinity in scent with the orange, that it is often called the "mock orange bloom." Other types of scent among white flowers are presented by the white lily, the jasmine, the tuberose, and the lily-of-the-valley. It is curious to observe, that among cultivated plants, white-flowered varieties are very often the most—if not the only—fragrant ones; this is the case with the white petunia [?] and a commonly cultivated white-flowered verbena [?]. It is also worthy of notice that many of the scents among white flowers are only pleasant when in very small quantity, and become absolutely disagreeable when intensified; this is the case, especially, with the hawthorn and white lily.

Among yellow flowers, the scent of the orange is often found, we may note, in the common broom, and in *Biscutella saxatilis* and other yellow Crucifers. The curious alcoholic odour which has earned for *Nuphar lutea* its English name of "Brandy-bottle" is found also in the yellow *Brugmansia floribunda*, as well as in the yellow catkins of *Salix caprea*. *Hippocrepis comosa* recalls the smell of cheese, and this odour attains its maximum in the blossoms of *Genista Scorpius*. The honey scent is found in several yellow-blossomed plants, notably in *Galium verum* and *Mahonia intermedia*.

Roses and pinks occur to one at once, when sweet-scented red-flowered plants are referred to; but with these exceptions it is difficult to characterize the odours of plants belonging to this series. But among lilac flowers a great resemblance in scent may be traced; thus the sweet odour of vanilla, which is so powerful in the garden heliotrope, is found again in different degrees of intensity in *Petasites fragrans*, *Valeriana officinalis*, and the common lilac; we meet with it also in *Plantago media*, which is exceptional among plantains in its fragrance and in its coloured corolla.

Blue flowers are very rarely fragrant, and when so, only in a slight degree. The blue variety of *Phyteuma spicata* exhales a faint perfume, and one or two campanulas are slightly scented. *Franciscea Hopeana* has, however, deliciously fragrant blossoms, which recall at once the scent of the orange and the tuberose; but although at first blue, they soon lose their colour and become white.

Certain species, the flowers of which are of sombre hues, are very fragrant. Thus in the early flowering *Calycanthus præcox*, one finds a multitude of odours, such as rose, jasmine and tuberose, harmoniously blended. The night-flowering stock (*Matthiola tristis*), *Hesperis tristis*, and one or two more, compensate by their fragrance for the absence of beauty of colour; while other dark-flowered plants, such as the henbane, have an intensely disagreeable odour.

Thus we see that it is not the most brilliant flowers which are the most fragrant, indeed, many of the most brilliant in colour have no scent whatever. The beautiful *Malvaceæ* of equinoctial America, the pelargoniums of the Cape, the passion-flowers [?], the gladioli, and some of the most striking *Leguminosæ* are destitute of perfume.

One or two conclusions as to the geographical distribution of sweet-scented plants may be arrived at from the preceding facts, united with many more which space will not permit us to cite. We have seen that a large proportion of pale and white blossoms are fragrant; and it is ascertained that these predominate in northern regions. We may therefore conclude that the relative number of odorous flowers is greater towards the poles than towards the equator. It would seem that the too powerful action of light and heat is opposed to the emanation of the odours of flowers; and we see many species, which are scarcely fragrant during the day, become so in the evening or at night. But if the odours emitted by the blossoms are more frequent in the North, the reverse is the case with the essences enclosed in the glands. Plants with fragrant leaves, aromatic fruits, and wood penetrated with essential oil, are scarcely found except in warm or tropical countries.

CITRIC ACID AND A NEW CLASS OF COMPOUND CITRATES.*

BY J. CREUSE.

Having undertaken the study of the citrates as a class, and especially of those of the citrates where the acid is combined with more than one base, the first difficulty I met was how to estimate citric acid without having recourse to the long and complicated process of an organic elementary analysis. I consulted the most recent publications and some eminent chemists without obtaining my desideratum, viz.—How to estimate citric acid free and combined, in the same direct manner as sulphuric or muriatic acid? The only thing then left for me was to try myself and find such a process, in which I succeeded, after many failures, including an explosion of citrate of silver.

This process is founded on the fact that while the alkaline citrates, the alkaline acetates and the acetate of baryta are freely soluble in alcohol sp. gr. 0·805 (63° Tralles), citrate of baryta is completely insoluble in that menstruum.

As the presence of alkaline acetates does not interfere with the reaction, this enables the chemist to estimate citric acid in almost any shape, for free citric acid may be saturated by an alkali, alkaline citrates may be analysed directly, and other citrates may be converted into citrate of potash without difficulty. This method presenting peculiar features, I will describe it in full.

If the citric acid to be estimated is in the shape of an alkaline citrate, take from 1 to 2 grams of the salt, dissolve in 10 to 20 c.c. of water, neutralize the solution with acetic acid if it is alkaline, with ammonia if acid; add a slight excess of a neutral solution of acetate of baryta and twice the volume of the whole liquid of alcohol 95°. Allow it to rest from twelve to twenty-four hours; the citrate of baryta, which is at first like a thick jelly, has by that time become denser and easier to wash. Transfer the whole to a filter; but as some of the precipitate always adheres to the sides of the vessel, it is recovered thus: pour into the vessel 10 to 15 c.c. of water, turn it round so as to wet all the parts where any salt adheres: citrate of baryta, being to a certain extent soluble in water, is soon taken up; add then double the volume of alcohol and pour on the filter with the first product. This being repeated a second time, all the citrate of baryta may be considered as collected on the filter. Wash this thoroughly with alcohol 63° and dry at a moderate heat. The precipitate thus obtained represents all the citric acid in the shape of the citrate of baryta; $3\,BaO, C_{12}H_5O_{11}$ with a variable proportion of water. But this salt is too hygrometric to give correct results if weighed directly; it is necessary to transform it into sulphate of baryta. This is done without difficulty by burning the filter and heating the ashes and precipitate to red heat with sulphuric acid several times till a constant weight is obtained. This being ascertained, the weight of the citric acid may be calculated within 2 milligrams.

If free citric acid is to be estimated, a convenient quantity may be first saturated with a titrated solution of caustic soda, which gives generally a little more than the actual strength; the citrate of soda may be then treated in the manner described above, which gives a result a little below the truth, and the average between the two will be within 1 milligram.

If it is necessary to estimate the citric acid of a non-alkaline citrate, soluble or otherwise, the analysis is conducted in this manner: a certain weight of the salt, from $\frac{1}{5}$–$\frac{2}{5}$ grm. is heated carefully with a solution of caustic soda or potash in excess; the heat must be applied long enough to decompose the salt thoroughly, but not enough to alter the citric acid. The liquid is then filtered, the filter washed as usual, and the liquor, exactly saturated with acetic acid, may be treated as an alkaline citrate. Care must be taken in this case, as in the others, that the saturation be as perfect as possible, for an excess of acetic acid causes the citrate of baryta to become soluble in alcohol, and an excess of alkali would precipitate some free baryta.

The solution of acetate of baryta used for these analyses may be prepared by treating pure diluted acetic acid by an excess of carbonate of baryta, heating to ebullition, adding some alcohol when cold, and filtering. This solution may be filtered to contain 5 per cent. of baryta, so as to know very nearly how much of it is necessary to precipitate the alkaline citrates thoroughly, without too much excess of the reagent. The addition of alcohol ensures its keeping unchanged for an unlimited period.

I need not describe here any analysis of citric acid, but I shall describe the analysis of some metallic citrates.

ANALYSIS OF CITRATE OF BISMUTH.

This citrate of bismuth is the salt obtained by precipitating acid nitrate of bismuth by an alkaline neutral citrate. It is insoluble in water, and may be obtained pure without difficulty; 2 grams of this salt were taken and decomposed by an excess of caustic potash, at a moderate heat. The precipitate of teroxide of bismuth well washed and dried was found to weigh 1·122 grm. The washings were collected together, saturated with acetic acid, treated by acetate of baryta and alcohol, as already mentioned, and the citrate of baryta thus formed, yielded 1·674 of sulphate of baryta, which corresponds to 0·788 of citric acid. The balance 0·09 represents the equivalents of water and the loss. Hence, we may figure the result thus:—

Teroxide of Bismuth .	1·122	or in other terms	1·170 = 1 equiv.
Citric Acid (anhydrous)	0·788		0·825 = 1 ,,
Water	0·086		0·090 = 2 ,,
Loss	0·004		
	2·000		2·085

From this we may deduct for citrate of bismuth the following formula:—

$$BiO_3, C_{12}H_5O_{11} + 2HO = 417.$$

ANALYSIS OF THE DOUBLE CITRATE OF BISMUTH AND AMMONIA.

This salt is commonly called ammonio-citrate of bismuth or soluble citrate of bismuth. It is obtained in two forms, in solution and in scales. In solution it may be either acid or neutral, in scales it is always acid on account of the loss of some ammonia during evaporation. It is very extensively used in medicine, but unfortunately is rather unstable in solution.

The analysis of the neutral salt offered no difficulty: 2·085 grm. of insoluble citrate of bismuth were weighed in a small porcelain dish, a little warm water added, and a small piece of litmus paper allowed to float on it. Then a filtered solution of ammonia containing 0·26 of ammonia to the 100 measures was cautiously added, the mixture being stirred all the time. As the last drop of the 100 measures fell into the porcelain dish, the litmus paper, red until then, turned blue, and in the same time the liquid became perfectly clear.

This gives for the neutral citrate of bismuth and ammonia the following formula:—

$$2NH_3, BiO_3.\ C_{12}H_5O_{11} + nHO.$$

The analysis of the salt in scales was conducted in this wise: 2·302 grms. of the ammonio-citrato of bismuth in scales were dissolved in a little warm water, and a small piece of blue litmus paper made to float on the liquid. The paper turned red immediately. Then the same filtered solution of ammonia already mentioned was added carefully till saturation; 25 measures were necessary, which corresponds to $\frac{1}{2}$ equivalent. This demonstrated

* Reprinted from the *American Journal of Pharmacy*.

already that the quantity of ammonia contained in the salt was $1\frac{1}{2}$ equivalent.

The liquid was then decomposed by caustic potash in excess, with the help of a moderate heat, etc., precisely in the manner described for the analysis of citrate of bismuth. The following numbers were obtained:—teroxide of bismuth 1·170, citric acid 0·823.

The proportion of ammonia being already known, the compound may be reconstructed thus:—

Teroxide of Bismuth	1·170 = 1	equivalent
Citric Acid . . .	0·823 = 1	,,
Ammonia	0·122 = $1\frac{1}{2}$	,,
Water	0·180 = 4	,,
Loss	0·007	,,
	2·302	

Or in chemical symbols:—

$$1\tfrac{1}{2}NH_3,BiO_3.\ C_{12}H_5O_{11} + 4HO = 460{\cdot}4.$$

I must say that in this salt I believe the proportion of ammonia may vary slightly, according to the mode of evaporation; this proportion, however, cannot fall below $1\frac{1}{2}$ equivalent without causing a decomposition.

ANALYSIS OF THE DOUBLE CITRATES OF BISMUTH AND POTASH, SODA AND LITHIA.

I believe these combinations have never been mentioned nor obtained yet by anybody. Yet, besides their interest in a chemical point of view, I think they will become of some importance to the medical profession, on account of their greater stability than the corresponding ammonia salt. For instance, a solution of citrate of bismuth and soda may be kept for weeks in warm weather without the addition of alcohol; the only change observable is the mouldiness common to all the diluted solutions of citrates, while a solution of citrate of bismuth and ammonia by the side of it is decomposed in twenty-four hours, letting the ammonia escape and forming a heavy insoluble sediment which contains almost all the bismuth.

The citrate of bismuth and soda, and the corresponding potassic salt are obtained easily by adding two equivalents of the caustic alkali to one of citrate of bismuth suspended in water, moderate heat being applied. They require, however, a little more care than the analogous ammoniacal combination, for any excess of potash or soda is liable to precipitate oxide of bismuth, a decomposition that ammonia will not effect under any circumstances. The double citrate of bismuth and lithia may be prepared by adding two equivalents of carbonate of lithia to one of citrate of bismuth, heat being applied.

The following are the formulas of these double salts:—

Citrate Bismu. and	Potash	$2KO,BiO_3.\ C_{12}H_5O_{11}+nHO$
,, ,,	Soda	$2NaO,BiO_3.\ C_{12}H_5O_{11}+nHO$
,, ,,	Lithia	$2LiO,BiO_3.\ C_{12}H_5O_{11}+nHO$

Not having obtained these compounds in scales yet, I have not been able to determine the equivalent of water.

My study of the citrates is far from being completed, but I have collected facts enough to justify me in proposing to divide the different citrates into three classes.

In the *first class* I would place all the various *simple citrates*, where the acid is combined with one, two or three equivalents of one base. These are so well known, that little need be said about them.

The *second class* would comprehend the *double citrates*, that is, those salts in which one equivalent of citric acid is combined with two equivalents of an alkali and one equivalent of another base, generally metallic. The simple citrate of that base is always less soluble than its double citrate. The various double citrates of bismuth mentioned in this paper may be considered as types of the second class, which contains a great number of them. Many are known and mentioned, such as ammonio-citrate of bismuth, of iron; potassic citrate of zinc, magnesia, etc.; their composition, however, is not stated anywhere to my knowledge.

The *third class*, or *quadruple citrates*, as I propose to call them, is not so well known,—the only one being, I believe, the soluble pyrophosphate of iron discovered in 1856 by E. Robiquet, my old friend and employer. These salts I consider as a combination in which an alkaline neutral citrate plays the part of a base and a peculiar metallic salt the part of an acid. I have abundant facts to prove the correctness of my theory, but I will only mention that I have already discovered the following new combinations which I place in the third class of citrates:— Phosphate, hypophosphite, valerianate, arseniate, sesquioxide of iron and several others, with citrates of potash, soda, lithia and ammonia.*

All these salts are very soluble, they all have a greenish colour and present no taste of iron.

SEWER GASES.

Epistolary effusions emanating from sanitary luminaries have lately deluged the public journals. If they have not succeeded in teaching us how to rid ourselves of the invisible death-dealing compounds arising in the form of sewer gases, it should afford their writers some satisfaction that their pet theories have been freely ventilated. According to the authorities alluded to, the gas is like Sir John Falstaff's otter—"you never know where to have it." Allow it to escape in one direction, and fancy you have got rid of it, "up it pops" in an unexpected quarter, "blows open your traps," and poisons your habitation. As the tide ebbs and flows so the gases surge about, and, from more uncertain and unknown causes, appear always ready to attack you at your weakest point and carry your defences. A storm will produce sudden and unequal commotion attended by uncertain phenomena, and it is practically impossible to adequately provide against and secure safety from this subtle evader of ordinary bolts and bars, by the precautionary measures hitherto suggested; even if such suggestions offered anything approaching to a sound solution of the problem involved.

It is proposed, in some places, to use trays containing charcoal under the sewer gratings, and ventilators, to send tall chimneys up into the air, and pipes with outlets above the eaves of houses, and, to use the expression of a Government official, to "dilute the gas by admixture with the outer air," in every possible direction. Such ideas, if carried out, would be, in fact, calculated to increase the amount of evil, and are a mere paltering with a subject of vital importance to the public health.

Is not the air of London sufficiently foul already? What is to become of these gases when they get abroad, containing, as is supposed, the germs of disease? Is the already-tainted air we are obliged to breathe to be further charged with such abominations? In our climate, with its oftentimes heavy atmosphere, the volumes of noxious gases carrying these disease-germs would rise only to a certain height, and probably spread and extend like a pall over the Metropolis. If a gentle breeze were to blow from the east, the perfumes wafted into Hyde Park and Kensington Gardens would remind the seekers of pure air and recreation of anything but the gales from "Araby the Blest;" and the inhalation by children and others of poisonous germs would thus transform a region of recreation into a plague spot.

That prevention is better than cure is an axiom which cannot be controverted. There is a radical remedy for the evil, and it seems incomprehensible that public attention has not been more particularly directed to it. Why are these sewer gases allowed to form? We have the power of binding and chaining the satanic agency, why then let it get abroad to seek whom it may devour?

The formation of sewer gases may be effectively prevented by arresting the decomposition of organic matter as it passes through the sewers. No systematic attempt

[* The solubility of phosphate of sesquioxide of iron in citrate of ammonia was noticed in 1859 by Mr. A. F. Haselden and the Editor of the *American Journal of Pharmacy*.]

has ever been made to deodorize our drains and sewers although the quantity of sewage to be dealt with and the effect of disinfectants on known quantities of organic matter has been ascertained. It is true that occasionally, under the dread of cholera, spasmodic efforts have been made in a desultory manner to deodorize drains in the summer time, but the system should be carried out all the year round. And it can be effected with greater economy than any other attempts to trifle with the difficulty, and inaugurate systems which have a positive tendency to accelerate the mortality of the multitude.—*Milk Journal.*

THE ALKALOIDS OF OPIUM.

BY O. HESSE.*

In order to obtain the rarer alkaloids, the black mother-liquors were taken (as obtained in the Robertson-Gregory process) from which the hydrochlorides of morphine, codeine and pseudomorphine had been separated. This liquor was first treated with an equal volume of water and precipitated with excess of ammonia; the clear liquor was exhausted with ether, and this again treated in the manner described in the Ann. Chem. Pharm. vol. cliii. p. 47. The alkaloids thus obtained can be now separated into two parts, the one insoluble, and the other soluble in excess of sodium hydrate. The alkaline solution, treated according to a former method, deposits first a small quantity of lanthopine, the filtrate from which contains neither codeine nor meconidine, for it is not coloured on warming with sulphuric acid; from it the author has obtained a small quantity of codamine. The solution is precipitated with ammonia, and the hard precipitate dissolved in a very small quantity of boiling dilute alcohol. White crystals are thereby obtained, from which the laudanine is separated by the action of hydriodic acid, with which it forms a difficultly soluble compound. *Laudanine* has the composition $C_{20}H_{25}NO_4$, instead of the formula $C_{20}H_{25}NO_3$, as formerly given; its melting-point is 166°. *Codamine* is found to melt at 126°, instead of 121°, and has probably the composition $C_{20}H_{23}NO_4$.

The portion insoluble in sodic hydrate, which must contain thebaine and papaverine, is dissolved in acetic acid, and the solution is neutralized in presence of alcohol, whereupon a crystalline precipitate is formed, consisting of papaverine and narcotine, which can be separated by oxalic acid. The melting-point of *narcotine* is given by the author as 176°, instead of 170°.

Papaverine, $C_{21}H_{21}NO_4$, when absolutely pure, dissolves in small quantities of sulphuric acid without coloration; generally, however, on warming a crystal of papaverine with concentrated sulphuric acid, a dark blue colour is produced, but when other crystals are added the colour is not increased; on the addition of water, papaverine sulphate is precipitated, as a resinous mass, which after a short time solidifies. No other alkaloid of opium gives this reaction; pseudo-morphine, which is the only one that is precipitated from its sulphuric acid solution by water, is obtained as a crystalline powder, not a resinous precipitate. Dilute nitric acid converts papaverine readily into nitropapaverine,

$$C_{21}H_{20}(NO_2)NO_4 + H_2O,$$

which occurs in colourless thin prisms, melting at 163°, and becoming yellow on exposure to light. When chloride of zinc and impure papaverine hydrochloride are allowed to act together for a short time, the impurities are decomposed, and a hydrochloride of an alkaloid is obtained, which agrees in properties with pure papaverine hydrochloride. The new alkaloid forms with acids very handsome crystalline salts, resembling the salts of cryptopine.

The neutralized acetic acid solution, from which the narcotine and papaverine have been separated, contains *thebaine*, which can be separated as the bitartrate by adding powdered tartaric acid. Instead, however, of tartaric acid, concentrated hydrochloric acid is added, which keeps the thebaine in solution, whereupon crystals of cryptopine hydrochloride are formed. From the dark coloured liquid still remaining, the author has been able to separate three other alkaloids, protopine, laudanosine and hydrocotarnine, by processes which will be described in another memoir.

Cryptopine, $C_{21}H_{23}NO_5$, melts at 217°, dissolves easily in chloroform, with difficulty in alcohol and is insoluble in ether. It is strongly basic, and forms salts which can be obtained in crystals; with hydrochloric acid it forms two salts $C_{21}H_{23}NO_5 . HCl + 6H_2O$, and with $5H_2O$, but the author has not obtained the salt with $2HCl$, as found by T. and H. Smith. It is precipitated from cold neutral solution by hydrochloric acid as a gelatinous mass, but from hot solutions prisms are deposited.

Protopine, $C_{20}H_{19}NO_5$, may be separated easily from the former alkaloid; it forms solid prisms with hydrochloric acid. It melts at 202°, and is somewhat difficultly soluble in alcohol and insoluble in ether.

Laudanosine, $C_{21}H_{27}NO_4$, dissolves sparingly in cold, but easily in hot benzol; it forms colourless prisms which melt at 89°. It is easily soluble in alcohol and ether, and has a basic reaction; with hydriodic acid it forms a very difficultly soluble salt.

Hydrocotarnine, $C_{12}H_{15}NO_3$, crystallizes in large colourless prisms, with $\frac{1}{2}H_2O$ as water of crystallization; they melt at 50°, and give up the half-atom of water. It volatilizes at 100° with partial decomposition, it dissolves easily in ether and alcohol; behaves like narcotine with concentrated sulphuric acid. Its reaction is basic, and it neutralizes dilute acids, forming salts which are easily soluble in water.

The author appends a valuable table, giving the colorations observed when the various alkaloids are dissolved in pure strong sulphuric acid, and in acid containing traces of iron.

	Dissolves in Pure Acid.		In Acid containing Oxide of Iron.	
	At 20°.	At 150°.	At 20°.	At 150°.
Codeine . . .	Colourless	Dirty green. .	Blue	Dirty green.
Codamine . .	Colourless	Dirty red-violet	Intense green-blue. .	Deep violet.
Laudanine . .	Very faint rose-red	Deep red-violet	Brown-red, similar to cobaltic nitrate solution	At first green, then deep violet.
Laudanosine .	Faint rose-red, somewhat stronger than laudanine	Ditto	Ditto	Ditto.
Cryptopine . .	At first yellow, then violet, and finally deep violet	Dirty green. .	Deep violet	Dirty green.
Protopine . .	At first yellow, then red, and finally bluish-red	Dirty greenish-brown	Ditto	Dirty greenish-brown.

THE CHICAGO COLLEGE FUND.

The following is a list of the subscriptions promised up to January 3rd, 1872.

The Members of the Chicago College of Pharmacy, notwithstanding their own great losses, will themselves provide a new building. Their appeal is solely for donations of articles for the Library, Lecture-Room and Museum. English Pharmacists, unable to give books, etc., are invited to send subscriptions of money, the whole of which will be expended by the Committee in the purchase of appropriate contributions.

Parcels of Books, Specimens of Chemicals, or Articles of the Materia Medica, Apparatus and Subscriptions may be sent to Professor ATTFIELD, 17, Bloomsbury Square, London, W.C. Cheques, crossed "London and Westminster Bank," and Post-Office Orders, drawn for "High Holborn," may be made payable to JOHN ATTFIELD. All Donations will be acknowledged in the PHARMACEUTICAL JOURNAL.

Amount previously acknowledged, £202. 13s. 6d.

The following is a list of the books promised up to January 3rd, 1872.

[Duplicates of books, lecture-specimens, etc., will be dealt with by the Committee, at their discretion, for the general benefit of the Fund, unless instructions to the contrary are forwarded with the parcels. Gentlemen are invited to inquire of Professor ATTFIELD, 17, Bloomsbury Square, London, W.C., as to whether or not copies of the books, etc. which they propose to give have already been contributed.]

Number of Volumes previously acknowledged, 160.

The Council of the Chemical Society of London.

A set of the Journal and Transactions of the Chemical Society.

E. Whalley, Kingston-on-Thames.

Beasley's Pocket Formulary. Blancard's Physical Dictionary. The New Edinburgh Dispensatory, 1801. Shaw's Edinburgh Dispensatory, 1737. The British Pharmacopœia and Family Physician. A Book on Spectacles.

J. Herbert, Kingston-on-Thames.

London Pharmacopœia, 1815, Translation.

S. H. Cooper, West Hartlepool.

Brougham on Instinct. Parkinson's Chemical Pocket-Book. Parkes's Chemical Catechism. The Chemist. Laplace's Celestial Mechanics.

B. M. Stoakes, Leamington.

Lescher's Elements of Pharmacy. Steggall's First Lines for Chemists and Druggists.

Joseph Ince, Vigo Street, W.

Wilson's Life and Works of Cavendish.

William Matthews, Wigmore Street, W.

Brande's Chemistry, 2 vols. Thenard's Analysis.

A. W. Smith, Rye.

Paris's Medical Chemistry. Mohr and Redwood's Practical Pharmacy. Thomson's Materia Medica, 2 vols.

Henry Cousins, Rye.

Professions, 3 vol. Wealth and Labour, 3 vols.

Messrs. Maw, Son and Thompson, London.

Book of Illustrations.

H. C. Baildon, Edinburgh.

Mohr and Redwood's Practical Pharmacy. Phillips's Pharmacopœia Londinensis, 1857. Brande's Pharmacy. Squire's 'Three Pharmacopœias.'

J. Whittaker, London Street, W.

Translation of the Pharmacopœia Londinensis, 1852. Steggall's First Lines. Selecta è Præscriptis, 1847. Pharmacopœia accommodata ad, etc. Fownes' Chemistry, 1844. Pharmacopœia Reformata, 1744. Lindley's Elements of Botany, 1841. Tomes's Dental Physiology.

Eugene Rimmel, 98, Strand, W.C.

Annales de l'Exposition du Havre, par Ribeyre. Rimmel's Book of Perfumes. Rimmel's Recollections of the Paris Exhibition. Specimens illustrating Manufacture of Perfumery.

John Beddard, 46, Churton Street, S.W.

Accounts of Belfast Harbour, 1786–1845. Papers by Dr. Davy. On the Commercial Relations of the United States. Archeia tēs Hellēnikēs Palingenesias. Report on Silks and Wines, 1835. Enquiries concerning Europe, 1758. Edinburgh New Dispensatory, 1786. Ditto, 1816. Bartlett on Consumption. P. Terentii Comœdiæ sex, 1739. Chemistry as exemplifying the Beneficence of God. Fownes. Xenophontis Œconomicus, 1750. Hunt on the Skin. Hamilton's Young Practitioner's Companion. Aikin's Materia Medica, 1785. Les Offices de Cicéron.

G. C. Walmough, 46, Churton Street, S.W.

Dewhurst's Medical Adviser, 2 vols. Meade's Manual of Prescriptions, 1835. Smedley's Practical Hydropathy.

Colchester Chemists' Association.

Muspratt's Chemistry, 2 vols. Lardner's Science and Art, 12 vols. Orr's Circle of the Sciences, 9 vols.

F. Sutton, Norwich.

Sutton's Volumetric Analysis.

T. and H. Smith and Co., Edinburgh.

Specimens of Chemicals.

C. R. C. Tichborne, 40, Mary Street, Dublin.

H. Draper,—Specimens of Anthraquinone and Picric Acid. *Dr. C. Cameron*,—The Stock Feeder's Manual; Handy Book on Food; Handy Book on Health; Lectures on Health; Original Papers and Reports. *Dr. E. Mapother*,—Lectures on Public Health; Medical Representation in Parliament; Animal Physiology; Original Papers. *C. R. C. Tichborne*,—Specimens of Bromide and Iodide of Potassium; Original Papers and Researches.

The Pharmaceutical Journal.

SATURDAY, JANUARY 6, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE NEW YEAR.

IT has been said that *les jours se passent et se ressemblent*, and the saying is partly true in the pharmaceutical as well as in the ordinary world. Being continually engaged in the endeavour to keep our readers abreast of the literature of pharmacy and its kindred sciences, we are, for this reason, unable, at the commencement of another year, to bring under their notice any remarkable novelty, but we may perhaps point to the issues of this Journal during the past year as containing a faithful record of pharmaceutical history in England during 1871. Compared with its predecessors that year will certainly bear a reputation for bellicosity; for pharmaceutists have not been allowed to rest satisfied with supping to the full of the horrors recorded of the Franco-German war, but have themselves been divided into two camps, for and against the proposed regulations for the dispensing and storing of poisons. Happily in this case it may be presumed that all the parties to the strife had the same object in view, although seeking it by different ways. Let us express a hope, however, that such contention may not be renewed.

One marked feature in the history of the year has been the attention devoted to the subject of provincial education, and the efforts that have been made by the local societies to obviate the hardships that may have been imposed upon insufficiently educated assistants and apprentices at the time of the Pharmacy Act. It is also satisfactory to see that there is a general feeling that this work once done, there should be an end to it, and that future apprentices should be made to acquire the education before entering the business.

Although this Journal has been the vehicle for publishing very many valuable papers written by English pharmacists, we are persuaded that much more remains to be done in this direction. A comparison of the number of contributors with that of the whole body would quickly show that they are but few in proportion, and that the same names occur again and again. May we suggest that in future more of our readers should contribute to the information of all by recording the results of such experience as they think may be useful. We are indebted for much assistance to the kindness of a few local secretaries and provincial members for matter of a more general interest. Here again were the number of our correspondents increased, and if every member were to make a point of forwarding information of any circumstance likely to be of interest, our record would be a more perfect one. To those gentlemen who have assisted us in the past we tender our heartiest thanks, and express a hope that they will still continue their valuable help.

One word in conclusion. We cannot hope that absence of complaint denotes entire satisfaction. The readers of this Journal are perhaps too varied in their tastes and requirements to render this probable; but if in the coming year any persons have suggestions to make as to ways in which these tastes and requirements may be more fully met, we trust that they will not hesitate to communicate them directly to the Editor, who will give them the most careful consideration.

THE BENEVOLENT FUND.

"No one liveth to himself," was the inspiration that guided WILLIAM ALLEN, CHARLES JAMES PAYNE, and divers others, when they first petitioned for a Royal Charter of Incorporation, having the double object of promoting education, and providing a fund for the relief of the distressed Members and Associates of the Society, their Widows and Orphans. The Fund has slowly yet steadily advanced. Once, indeed, a certain amount of apathy seemed to imperil its existence. Great efforts were then made to enforce its claims, nor can the untiring services of the late Mr. BENJAMIN ORRIDGE ever be forgotten. The opening of a New Year speaks to us most eloquently of our duty to those around us. Let us listen to the voice, remembering that while it is always one of the noblest privileges to help our fellows, in this case even selfishness may stimulate our liberality, for no man living can count upon the chances of his own position. There are two plain facts that cannot be too well understood. A sum of £12,000 is invested in our Benevolent Fund, and at this we rejoice. The interest provides for twelve Annuitants, *but* there are thirteen. One Annuity is therefore paid out of the annual subscriptions, which should be exclusively devoted towards meeting the numerous claims for temporary assistance. £1000 is therefore urgently required as an investment, in order to allow the operations of the charity to flow in their proper channel.

Secondly, we are at liberty to appeal for aid with the utmost confidence, for the Fund is now available not only to persons connected with the Society, but also for the relief of all Chemists and Druggists. We learn with pain that a vast majority of these latter contribute most slenderly to the subscription list of this admirable institution. Surely, distress, poverty, and privation should bind us all together in one common brotherhood. Great praise is due to some of our Local Secretaries, who, by their own example and energetic canvass, have rendered essential service. They have made the *existence* of the Fund known, and in a direct manner pointed out its usefulness amongst the trade.

It is worthy of notice, that wherever the Local Secretary himself takes an interest in the work, the Fund flourishes, the good seed sown yields often an abundant harvest, and the list gives evidence that in some towns *every* Chemist and Druggist has contributed; while in the same place there are not wanting the names of many totally unconnected with pharmacy.

Must we in this century, an age of noble endeavour and self-denial, defend or praise benevolence? Shall we, who with unsparing hand help other countries, one not even speaking our own language, neglect our home duties, and starve our home liberalities?

Let not the widow and the orphan plead in vain; let misfortune tell her story of want and wretchedness, and let scarce and dear provisions for once turn orator!

So shall we enter upon the New Year with lighter hearts, for we shall have helped to bear each others' burdens, and our own fireside shall glow all the more brightly when we reflect that we have kindled hope in many a desponding soul; and know that we have tried to resemble the Great Pattern who himself became poor, that we through his poverty might be made rich.

THE PHARMACEUTISTS' ASPECT OF THE MEDICAL DECLARATION RESPECTING ALCOHOL.

We published last week the declaration respecting alcohol, which has been, and is, a leading subject of discussion in medical and other circles. There are, of course, pros and cons in this as in most other questions, but there can be little doubt that the "nip" of sherry between meals, and its continual multiplication between noon and the dinner hour, has much to do with chronic alcoholism, a disease that has increased more than cent. per cent. during the past ten years. But we refer to this subject again, in order to indicate that there is an aspect of the matter specially pertinent to pharmaceutists. Will any of our readers (east or west, no matter) pause to consider how often they, or their assistants, are asked for "pick-me-ups" by their male, and for that popular composition commonly known as "red lavender," by their female clients? Have they any idea at all as to what proportion of gentian, lavender, and other tinctures, of eau de cologne, chloral hydrate, and compound spirits of ammonia sold is taken for really legitimate and beneficial purposes? These are questions well worthy of consideration, and we believe that those of our readers, who consider them carefully in all their bearings, will come to the conclusion that the sale of these articles for the plain purpose of producing an artificial stimulus to mental or physical exertion has, during the past few years, increased in a most marked degree, and to a most pernicious extent. We believe that chemists could, if required, give most valuable evidence on this point; for it is perfectly well known to all medical men practising in London that many of their upper and middle-class clients of the other sex, not daring to keep a brandy bottle in their closets, find nevertheless a convenient and (as they suppose) a safe substitute in the imbibition of small and oft-repeated doses of lavender tinctures, eau de cologne, etc. And it is as patent that our readers must know a great deal about the way in which these articles are obtained, and can form also a tolerably correct idea as to the rate of consumption. In all matters relating to the health and well-being of our populations the physician and the chemist may work most usefully together, and we take leave to suggest that, on some of the points above indicated, pharmaceutists might very well strengthen the hands of the medical profession in their laudable endeavours to stem the alcoholic current that is sapping the foundations of many grand intellects, and many brilliant minds in this big city.

THE LIBRARY.

It will be seen that in compliance with a wish which has been expressed,* the Council has decided that the Library shall be kept open on Tuesday and Thursday evenings from eight to ten o'clock. This arrangement is to be commenced at once, and trial made of it for three months. On two former occasions the experiment was tried, but the attendance was so small that it was discontinued; it is therefore hoped that now the Council has again provided for the alleged need there will not be wanting those who are ready to avail themselves of the privilege.

We are informed that the Board of Trade has decided to substitute chlor-alum for the solution of chloride of zinc, at present included in the scale of medicines and medical stores, issued and caused to be published by that Board, in pursuance of the "Merchant Shipping Act, 1867."

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

January 3rd, 1871.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

Present—Messrs. Atherton, Betty, Carr, Greenish, Groves, Hills, Sandford, Shaw, Smith, Sutton and Williams.

The minutes of the last meeting were read and confirmed.

The Report of the Finance Committee was presented, showing on the General Fund Account a balance in the Treasurer's hands of £758. 1*s*. 9*d*.

On the Benevolent Fund Account a balance of £198. 18*s*. 5*d*.

* See *ante*, p. 380.

The Report of the Finance Committee was received and adopted, and sundry payments ordered.

Resolved—That the Report of the Benevolent Fund Committee be received.

Resolved—That the Treasurer be requested to pay the Thirteen Annuitants respectively their quarter's annuities to Lady Day next.

Resolved—That, in accordance with the Bye-laws, two hundred pounds stock be purchased on the Benevolent Fund account.

The Report of the House Committee, giving the tenders for the alterations in the basement, and other work previously decided on by the Council, was presented, with a recommendation that the tender of Messrs. Patman and Fotheringham be accepted.

Resolved—That the Report and Recommendations of the House Committee be received and adopted.

The Report of the Library, Museum and Laboratory Committee was presented, recommending

That the following books be purchased for the Library:—Wanklyn and Chapman's 'Water Analysis,' 2nd ed.; Beasley's 'Pocket Formulary,' 9th ed.; Page's 'Text-Book of Geology;' Lyell on Geology; Cavendish Society's publications.

That the Library should be kept open on Tuesday and Friday evenings from 8 to 10 P.M., and that this arrangement should be continued, as an experiment, for three months, a record of attendances being kept.

Resolved—That the Report and Recommendations of the Library, Museum, and Laboratory Committee be received and adopted, and that an advertisement be inserted in the Journal of the Society to the effect that the Library will be open on Tuesday and Friday evenings from 8 to 10 P.M.

Resolved—That the Report and Recommendations of the Parliamentary Committee be received and adopted.

REPORT OF THE BOARD OF EXAMINERS.

December, 1871.

ENGLAND AND WALES.

	Candidates examined.	Candidates passed.	Candidates failed.
December 20, Major	5	5	0
” ” Minor	22	13	9
” 22, ”	22	14	8
	49	32	17

PRELIMINARY.—Certificates received in lieu of this Examination:—4.

Resolved—That the following, having been duly registered as Pharmaceutical Chemists, be respectively granted a Diploma stamped with the seal of the Society:—

Brown, Frederic Peter ...... Grantham.
Brown, James .... Ampthill.
Forsbrook, William Henry .. Birmingham.
Jones, William Ellis .... Barmouth.
Keen, Benjamin .... Uppingham.

Resolved—That the following Pharmaceutical Chemists be, and are hereby elected Members of the Society:—

Catterns, Heneage Parker .... London.
Clarke, Arthur Henry .... Croydon.
Delves, George .... Exeter.
Holton, John Henry .... New Grimesthorpe.
Keen, Benjamin .... Uppingham.
Maddock, William Thomas .. Portsmouth.
Naldrett, George Thomas .... London.
Ward, John Slinger.......... York.

Resolved—That the following Registered Chemists and Druggists be elected Members of the Society:—

Buckland, Edwin .... Sutton-in-Ashfield.
Crook, Charles .... Mirfield.
Fisher, Edwin .... Ashton-under-Lyne.
Jeffery, Henry .... Bristol.
Jones, Benjamin .... Twickenham.
Jones, Thomas .... Oswestry.
Lea, Edward................ Whitchurch, Salop.
Litherland, Henry .... Wigan.
Matthews, Henry............ Bristol.
Woods, William .... Plymouth.

Resolved—That the following having passed their respective examinations, and being in business on their own account, be elected "Associates in business":—

MINOR.

Cooper, William John........ Cockermouth.
Linklater, James .... Lerwick.
Nicholson, Edward .... Lindley.

MODIFIED.

Bardsley, William .... Peckham.
Barrow, James Horsfield...... Southport.
Bowles, William James ...... London.
Burgess, Frederick Augustus.. London.
Dubois, Bernhard William.... London.
Gray, James Thomas .... Crewe.
Southern, Joseph .... Manchester.
Woolrich, Francis .... Nottingham.

Resolved—That the following, having passed their respective examinations, be elected Associates of the Society:—

MAJOR.

Wilford, Josiah.............. Newport Pagnel.

MINOR.

Beach, Tom Clarke .... Great Malvern.
Bryars, William Hudson ..... Goole.
Fuller, John William .... London.
Graham, John .... Dumfries.
Green, Thomas.............. Belfast.
Hargreaves, Joseph .... Liverpool.
Hensby, Robert Place .... Maidstone.
Hill, William .... Louth.
Hinksman, John .... Edinburgh.
Kennerley, William.......... Manchester.
Leman, Alexander .... Aberdeen.
McNaught, Archibald........ Greenock.
Mellor, Thomas .... Bury.
Peake, Arthur .... Stalybridge.
Place, John Newton .... Cambridge.
Saunders, Thomas Samuel .... Notting Hill.
Tuck, William James .... Portsmouth.
Tucker, William Tyler ...... Worthing.
Wade, James Henry .... London.
Williamson, Nicholas .... Whitehaven.
Windlo, John Thomas........ Norwood.

MODIFIED.

Frizell, Richard William ..... London.
Harcus, John................ Newcastle.
Ross, William .... Galashiels.
Sansom, Henry.............. Hitchin.
Starie, William Chantler ..... Bristol.
Taylor, Alfred .... Kendal.
Womack, Thomas .... Barnsley.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

Second General Meeting; Mr. G. DYMOND, President, in the chair.

Mr. HENRY W. JONES read a paper to the Associates on "Volumetric Analysis." Time not allowing the lecturer to complete his experiments, the PRESIDENT proposed that Mr. Jones should attend another evening for this purpose; he will therefore read a second paper on the same subject.

Third General Meeting.—Mr. J. B. WILLIAMS read a paper on "The Attractions of the Study of Botany." After dwelling at some length on its fascinations, Mr. Williams entered somewhat minutely into the different systems of the various botanical authorities. In the course of the discussion which took place afterwards, it was suggested that if the Association could arrange for members or students attending the Botany Classes to visit the Botanical Gardens, it would be of great assistance to them.

The next paper will be read on Thursday, January 25th, in the rooms of the Association, 24, Quadrant, New Street, Birmingham.

Parliamentary and Law Proceedings.

POISONING OF TWO CHILDREN BY A "SLEEPING MIXTURE."

The *Huddersfield Examiner* reports the death of two children, from the improper administration of a "sleeping mixture," prepared by the children's mother. It states that the children, who were twins six weeks of age, appeared to be suffering from pains in the stomach that caused them to scream a great deal, and the mother was recommended by a neighbour to try a decoction of opium and aniseed. The neighbour obtained the ingredients and gave them to the mother, without any instructions as to the quantity to be prepared or taken. The mother, having made a decoction, gave about two teaspoonfuls of it to one of the children. Late in the evening the child became very ill, and about half-past nine it died, it is supposed from the effects of the decoction that had been administered to it. She had also given some of it to the other child, and next morning it became so very ill that Mr. Goodall, surgeon, of Lockwood, was called in, and prescribed for it. The child died about three o'clock on Monday morning, from the same cause as its twin sister. It is stated that the box containing the opium, which was given to the neighbour, had no label upon it, nor were there any directions as to its use. This will doubtless be matter for inquiry at the inquest which will have to be held.

Obituary.

DR. LE CANU.

We have received information of a loss to French pharmacy in the person of Dr. Louis-René Le Canu, who died in Paris on the 19th of December, at the age of seventy-one years. The deceased gentleman was a Member of the Academy of Medicine, Professor at the École Supérieure de Pharmacie of Paris, Member of the Hygienic Council for the Department of the Seine, etc. He was also a member of several learned societies, and an officer of the Legion of Honour and of some foreign orders.

The contributions to scientific literature by Dr. Le Canu have been very numerous. Among them may be mentioned several memoirs upon the chemical constitution of blood, urine, milk and fat; an 'Analytical Examination of Hermodactyls,' 'Report on the Vegetable Alkaloids,' 'The Adulterations of Flours,' 'An Examination of a Mineral imported from America, containing Borate of Soda and Borate of Lime,' 'A Chemical Examination of Castor Oil,' 'A Complete Course of Pharmacy,' etc. He was also the author of some papers in conjunction with Messrs. Blachet, Bussy, Planche, Serbat, and others.

CHARLES SIDEY, L.R.C.S. EDIN.

Edinburgh has lost an able practitioner and a public-spirited townsman in Mr. Charles Sidey, who died at his residence in Hanover Street on Wednesday, the 27th ult. Mr. Sidey began his professional career as a chemist and druggist in the vicinity of Holyrood. In this capacity he qualified himself for the diploma of the Royal College of Surgeons, which he took in 1817. Entering immediately thereafter on general practice, he rapidly acquired the confidence and support of a large *clientèle* of patients, and was especially esteemed for his sagacity and skill in treating the diseases of children. He was much respected by his brother practitioners, and enjoyed the personal friendship and professional intercourse of Abercrombie, Alison and Syme. The last-named gentleman in particular, during the illness that ultimately carried him off, consulted Mr. Sidey regularly as to the nature of his malady. For more than half a century Mr. Sidey continued to maintain the confidence he had so deservedly won from the community, and his hale and vigorous bearing seemed to give promise of many years of active life in store for him. But suddenly, on the morning of the 27th ult., he was seized with a spasm of the heart, became insensible, and never rallied. He was in his seventy-sixth year, and leaves, among several sons and daughters, Dr. James Sidey, well-known in Edinburgh, not only for professional proficiency, but for very considerable talent as a writer of humorous and satirical songs.

MR. JOHN LESSEY.

We regret to announce the death, on the 22nd of December, of Mr. John Lessey, pharmaceutical chemist, of Croom's Hill, Greenwich. The deceased gentleman had for many years been connected with the Pharmaceutical Society, having joined it in 1852 as one of the Founders.

MEETINGS FOR THE ENSUING WEEK.

TUESDAY, Jan. 9. ......*Royal Institution*, at 3 P.M.—"Ice, Water, Vapour and Air." By Professor Tyndall.
Photographic Society, at 8 P.M.

THURSDAY, Jan. 11. ......*Royal Society*, at 8.30 P.M.
London Institution, at 4 P.M.—"The Philosophy of Magic." By J. C. Brough.

FRIDAY ....*Quekett Club*, at 8 P.M.

SATURDAY......*Royal Botanic Society*, at 3.45 P.M.

BOOKS RECEIVED.

ON FLUID MEAT: a New Preparation of Meat, especially adapted to Weak Stomachs and for Invalids generally, with Remarks on Food. By STEPHEN DARBY, F.C.S., Pharmaceutist. London: Churchills.

YEAR-BOOK OF PHARMACY: comprising Abstracts of Papers relating to Pharmacy, Materia Medica and Chemistry contributed to British and Foreign Journals from July 1, 1870, to June 30, 1871. With the Transactions of the British Pharmaceutical Conference at the Eighth Annual Meeting held at Edinburgh, Aug. 1871. London: Churchills. 1871.

DE L'ACONITINE CRISTALLISÉE ET DES PRÉPARATIONS D'ACONIT: ÉTUDE CHIMIQUE ET PHARMACOLOGIQUE. Par H. DUQUESNEL, Pharmacien de 1re Classe, membre de la commission d'hygiène publique et de salubrité du Xe arrondissement. 38 pages. Paris: J. B. Baillière et Fils. 1872.

REPORT OF THE SANITARY COMMITTEE TO THE COMMISSIONERS OF SEWERS OF THE CITY OF LONDON ON SPURIOUS AND UNSOUND TEA AND THEIR PROCEEDINGS THEREON. London: Ordered to be printed by the Commissioners. 1871.

The following journals have been received:—The 'British Medical Journal,' Dec. 30; the 'Medical Times and Gazette,' Dec. 30; the 'Lancet,' Dec. 30; the 'Medical Press and Circular,' Jan. 3; 'Nature,' Dec. 30; the 'Chemical News,' Dec. 30; 'English Mechanic,' Dec. 29; 'Gardeners' Chronicle,' Dec. 30; the 'Grocer,' Dec. 30; the 'Journal of the Society of Arts,' Dec. 23; 'British Journal of Dental Science' for January; the 'Florist and Pomologist' for January.

COMMUNICATIONS, LETTERS, etc., have been received from Dr. De Vry, Mr. J. Mason, Mr. E. Rice, Mr. Pocklington, "Unitas," "Ferrum," "Gignosko."

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

SYRUP OF TOLU.

Sir,—Your correspondent Mr. Goodwin Mumbray has evidently misunderstood the purport of my paper upon syrup and resin of tolu, there being in it no question as to the method of preparing the syrup; it points to what takes place during the process, and the employment of the residual resin. I would not trespass upon your space, but I fear your correspondent's letter may in another way tend to mislead. He writes, "It will occur to any practical chemist and druggist that the ordinary syrup of balsam (formerly Syr. Tolutani, Ph. Lond.) is made by adding ℥j Tr. Tolu to 2 simple syrup." As far back as 1745–1788, and again in 1809, and I believe in every subsequent Ph. Lond., the mode of preparing the syrup was identical with the present; in the Dublin Pharmacopœia, 1850, the same process was adopted, the Edinburgh Pharmacopœia being then the only one, as far as Great Britain was concerned, which ordered the tincture in making the syrup. Upon the construction of the P.B., the London form was chosen for adoption. Undoubtedly some did follow, and possibly may now, the ready mode of preparing the syrup by means of the tincture, but it was not, and is not, the process of the Ph. Lond. or the P. B., neither so pleasant to the taste nor so sightly. Either your correspondent or the printer, most likely the latter, has made a mistake as to proportions;* for, when the tincture was used by the Edinburgh or Dublin Colleges, it was in the proportion of ℥j of tincture to a pound and a half or two pounds of syrup, and not ℥j Tr. Tolu to 2 simple syrup. The proper quantity of syrup is evidently omitted. The balsam, dissolved in spirit and minutely divided by the syrup, might yield an article which would not cause the same effect as the undissolved crystalline substance properly directed to be separated by filtration when cold.

I have never seen a clear bright syrup made with the tincture, but, following the directions of the P. B. process, and which I believe to be the best, no difficulty need be experienced by any one in producing a good-flavoured and bright syrup.

With respect to the compound tincture of benzoin, or Friar's balsam, the old folks, as mentioned, have faith in it, and for other maladies besides coughs; but they usually drop it on sugar, and take it in that form.

To your other correspondent, Mr. J. Knowles, I am indebted for reminding me of another purpose for which the residual resin may be used, viz. the preservation of lard and pomades; it may be seen at page 252, Vol. V., Second Series, PHARMACEUTICAL JOURNAL, that I mentioned the same thing in a paper upon ointments, read at an evening meeting at that time,—my attention having been drawn thereto in a work written by the late M. Moquin-Tandon. I then stated that, in the event of a scarcity of benzoin, the resin of tolu might answer the purpose, but that it has not the same fragrant odour; and that some lard which I had prepared with it as an experiment, after fifteen months' keeping was much changed, though still retaining some of the tolu odour.

A. F. HASELDEN.

18, *Conduit Street, January 1st*, 1872.

IN MEMORIAM.

"From information I received," I found myself, some three or four weeks ago, in the Grange Road, Bermondsey. A chemist and druggist (an old member of the Pharmaceutical Society) had passed away from this troublesome world by his own hand, and the fact had not been recorded. To the West-end chemist the Grange Road, Bermondsey, for all practical purposes, is an absolute myth—a something possibly heard of, but never seen. Who would dream of taking an omnibus from the Bank or the Royal Oak to the Grange Road, Ber-

* The mistake cannot be entirely attributed to either our correspondent or the printer; it had its origin in the illegibility of the "lb.," which might easily have been taken for something else, or overlooked altogether, which last occurrence actually took place.—ED. PHARM. JOURN.

mondsey? There, however, it is, as may be learnt from the maps, a somewhat imposing thoroughfare leading from nowhere to nowhere. Nevertheless a considerable amount of traffic passes along it from end to end. The shops are small and of the poorer class. Time was when the Grange Road, Bermondsey, was better in most respects than it is now. There could be no earthly reason why a chemist should not gain there a comfortable livelihood, and accordingly a chemist there was, and has been, until a week or two since, when the contents of that deadly one-ounce stoppered bottle so well known to the trade did its work, as it always will do, surely and but too well. The bottles and their contents remain, it is true, but the familiar presence of the owner is no longer a plain and simple fact.

Poor Elkington's shop is well situated for trade, and he was himself a good tradesman. One of the old school, his motto was "business," and, compelled almost by surrounding circumstances, he went in for those dreadful trade precepts (oh, what a shudder their remembrance creates!) which, in these enlightened pharmaceutical days, seem to belong to a past age. As a friend and acquaintance he is remembered with great regret by those who knew him best. His bearing was that of a gentleman, whilst his kindly and cheerful disposition rendered him a genial companion to all those who were one with him in sentiment and thought. So much the more is the psychological fact now to be recorded a simple mystery. All was apparently well at eleven o'clock on the Sunday night. Nothing unusual was, or could be, observed in his manner or conversation, and yet by some unaccountable perversity or paradox of human nature, he shortly afterwards went deliberately to his poison cupboard, took therefrom the bottle already referred to (acid. hydrocyan. dil.), ascended to his room, drank from it, and got quietly into bed. Here was he found by the housekeeper the next morning lifeless and cold. It was impossible to be mistaken. The fact was only too clear—he had been dead for some hours. So passed away poor Elkington from all earthly care into the quiet grave! Whate'er may betide now, certain it is he will never again be seen behind that neatly-kept and well-to-do counter in the Grange Road, Bermondsey.

Can we point a moral or adorn a story like this? At the inquest the jury returned a verdict of "temporary insanity." Why, then, was this man, for the time being, insane so to put it? There was no pecuniary embarrassment, no grievance or difficulty that would occupy a serious, not to say suicidal, thought in the minds of the majority of men. No scrap or document of any kind was left to tell the secret of the act. Down, deep down in the heart did the same lie unsuspected and unknown. There are men who will laugh at disappointments and glory in overcoming difficulties as they crop up before them; but this is not given to all. A temperament and condition of mind keenly and nervously organized is not the combination best suited to battle through life with its interdependent conditions of failure and success. Disappointments are heightened, losses are accounted ruin, pain cannot be borne, and despair is ever at hand to whisper, if need be, the last resource of a desperate will.

"Trifles light as air
Are to the jealous confirmation strong
As proofs of holy writ."

Thus are the heightened faculties of the mind ever ready to strengthen doubt and confirm suspicion—to cast aside hope and to lose all faith in the realities of a possible future. This, however, it must be said, is by no means incompatible with a cheerful demeanour whilst the path of life is strewn with flowers, and the cord runs smoothly over the wheel of time. We are so accustomed to the term "temporary insanity," that it does not at all alarm us. It is simply a generous interpretation of something wrong in the machinery of human life, mayhap of passing significance, yet all-sufficient for its fell purpose. Can we learn anything from it, this "temporary insanity," which we may apply with advantage to ourselves? Were we all philosophers, we might learn much; but the difficulty of contending against natural susceptibilities and transmitted or inherent weaknesses is terribly great. Nevertheless, could we but feel how much real truth there is in our commonplace humanity, we might well pause and consider. An able writer has given us an idea which, if not an abstract doctrine, is at least an intelligible precept. "Taking things easy is defensible in theory, and healthy and satisfactory in practice." That this mood falls short of the highest is not to be denied, and to "take things easy" with error and sin is shameful treachery to God. But life is not long enough to be for ever playing at "much ado about nothing." If "taking things easy" denies to us a place in the foremost ranks of the world, it "at least saves us from losing our wits at bugbears and scarecrows."

All honour to those gifted men who are the pioneers of our faith in that which is and shall be! But "judge how we will of the fact, the deepest thinkers on life have ended with being more impressed with the insignificance than the importance of its achievements, interests, and endeavours." Self-knowledge is the essence of all knowledge. We may not be easy-going people, but the opportunity is at least afforded us of learning wisdom from experience. If we cannot altogether control the insidious workings of original temperaments, we can, as far as may be, avoid the shoals which impinge upon them. The vast majority of mankind must follow the lead of those colossal minds which rule the world, and, leaving our destiny in their hands, to what comparative insignificance do we not reduce all that remains! If the "stings and arrows of outrageous fortune" cannot be borne, better, if such be possible, avoid them than seek a remedy in the deadly phial. Happily, in our interpretation of the mental phenomena leading to suicide, we are not unmindful of the aphorism:—

"To err is human, to forgive divine."

And when, unfortunately, a brother pharmaceutist, either in the east or the west, is brought to this, it is impossible to withhold a regretful sympathy that there should have existed a hidden cause for so sad and painful a story. The case of poor Elkington is still a mystery, and likely to remain so. Had he been able to overmaster the sudden grief which assailed him, he would doubtless have discovered its true meaning and learnt something of the uses of adversity. As it is, it remains only to strike his name from the register, and to record the fact of his death as an unfortunate episode to be recalled only with the very deepest regret. This alone can we do. "The rest is silence."

January 1st, 1872. W. WILLMOTT.

EARLY CLOSING.

Sir,—It gave me great pleasure to read Mr. Stables' letter on this subject. I would suggest, as a commencement, that after a certain time, say the usual hour that other trades suspend business, all customers should be charged 25 to 50 per cent. on all articles they may require (perhaps excepting physicians' prescriptions), which is only what a mechanic would do if you wished him to work overtime.

I have no cause for complaint myself, as my hours are short compared with many, 7.30 A.M. to 8 P.M., with occasional customers afterwards, principally for 1*d.* pills, castor oil, linseed meal, seidlitz powders, and occasionally a prescription; most, if not all, might have been obtained before closing, and no doubt would be if an extra price were charged.

The chemists in this town also close on Wednesday at 5 P.M. all the year round. Of course some one must remain in charge, but still it gives great facility, especially during the summer months, for a pleasant stroll, and in the winter months for study and friendly society.

I think I may truthfully say there is not a tradesman who would go back to the old hours again. The best way to prove how it works is to write and ask the chemists how they have found it work.

What has been done in this town may, and I hope will, be done in other provincial towns at no very distant date. We may then see our friends in London and other large towns follow our example. We ought to be able to make a comfortable competence without making slaves of ourselves, if we work with a will at the proper time.

In conclusion, I hope, with Mr. Stables and many others, that some of our leading men will take the matter into consideration. THOMAS BUCK.

Chelmsford, January 1st, 1872.

Bisulphite of Magnesia.—We have received a letter from "A Graduate of Cambridge" in reference to this subject, but since it treats almost entirely of a medicine the nature of which is not indicated by the name, we are unable to insert it.

J. S. H.—The fragments of the plant sent are insufficient for identification. A more complete specimen, together with the history of the plant, would be required for the purpose.

John Bradshaw (Congleton).—The thick consistence is preferred by many medical men. Probably your difficulty might be overcome by making the preparation brought for it.

THE PARIS SCHOOL OF PHARMACY.

BY WALTER HILLS.

In former papers on the "École de Pharmacie" in Paris, I have given short notices of the laboratory work and of the lectures; now I would say a few words respecting the examinations.

As is generally known, there are two grades of pharmaceutists in France, viz. "la première classe" and "la seconde classe." Members of the former only can establish themselves in *any* part of the country, while those of the latter must confine themselves to the special department or district they have chosen, and for which they have been inscribed; and legally, they have no right to establish themselves in either of the three cities of the faculties, Paris, Strasbourg,* and Montpellier. I say legally, for I believe that many of this class have, for some years past, kept open pharmacies in Paris, and although the Government has, to some extent, closed its eyes to the fact, still it may wake up at any moment, and inflict a fine for every day of disregard of the law.

To become a "pharmacien de première classe," it is necessary, before repairing to either of the cities of the faculties, to have served three years in an open pharmacy, and also to have passed the examination of the "Baccalauréat-ès-Sciences." After this, three years are required at one of the above schools; that is to say, that the student's name must be on the books for that period, and his numerous fees regularly paid, even if he does not make his appearance until the examination day. Thus no expenses are saved, although a man works up entirely in the country, or at his own home. During these three years, five "semestriel" and four finishing examinations must be passed; on the successful issue of each of which, as well as at the commencement of his studies, one or more inscriptions are given to the candidate, and twelve of these inscriptions are necessary before he is duly admitted to be a member of the first class. The "semestriel" examinations serve as a test to ascertain that the student has made the best use of his time during the session, and they treat of the subjects that have been especially brought before his notice during that term. The other four examinations, which are all passed towards the close of the three years, are as follows:—

I. Pharmacy, Chemistry, Physics, Toxicology.

II. Zoology, Materia Medica (specimens and history), Botany (recognition of plants, etc.), Mineralogy (recognition of specimens and history).

III. Synthesis. Ten chemical, and ten pharmaceutical preparations. The candidate describes the process he intends to employ in making these, and

IV. He has both to exhibit these preparations, which he has made in the interval in the laboratory, and also to describe them more fully than in the previous examination.

The fees for a candidate for the "première classe" are—

Inscriptions (12 à 30 fr.)	360 fr.
Travaux pratiques pendant les trois années, 100 fr. par année	300 ,,
Cinq examens semestriels (30 fr. par exam.)	150 ,,
Les deux premiers examens de fin d'études (80 fr. par exam.)	160 ,,
Le troisième examen de fin d'études	200 ,,
Trois certificats d'aptitude (40 fr. par certif.)	120 ,,
Diplôme	100 ,,
Total	1390 fr.

And now we come to the requirements for a "pharmacien de deuxième classe."

I. Six years' apprenticeship in a pharmacy.

II. "Examen de grammaire" (answering to our Preliminary).

III. "Inscription à 30 francs."

IV. A "semestriel" examination, and one year of laboratory work.

V. Finishing Examination.

The expenses are:—

Inscriptions de l'école supérieure de pharmacie (4 à 30 fr.)	120 fr.
Épreuves pratiques	120 ,,
Trois certificats d'aptitude (40 fr. par certificat)	120 ,,
Diplôme	100 ,,
Total	460 fr.

All of the examinations of which I have spoken are public, and consequently I was able to be present at a considerable number of them. The examination-room has somewhat the appearance of a small court of justice. At the upper end is the semicircular table for the professors, of whom there are usually three or four, the chairman wearing his hood and gown; in the centre is the raised seat for the candidate, and at the lower end are the seats for the public.

In the "herboriste" examinations, which are held during the summer months at the School of Pharmacy, and in which a great proportion of the candidates are women, the public end of the room is equally divided for the two sexes. The Professors usually retire for a minute or two's consultation after each examination, and on their return the chairman announces aloud the success or failure of the candidate; and if the former case, he adds the words, moderately well, well, or very well, according to the amount of satisfaction given.

The length of time given to each subject in an examination is ten minutes, which is regulated by a sand-glass passed in rotation to each examiner.

In conclusion, it will be seen that the time and expenses requisite for the acquirement of a diploma of the first class, are by no means unimportant; and it must be borne in mind, as stated above, that even if a man works up at his own home, he must be duly inscribed on the books and regularly pay his fees for the usual term of years, although he is not personally profiting by the instruction given at the lectures and in the laboratory. Thus I found that only a very small proportion of the students whose names were on the laboratory books, came to benefit by the instruction and advice of the distinguished manager, M. Personne.

As to the amount of knowledge required by the candidate in the examinations, I believe, from first to last, it is more extended than in our own in England, and this should not be forgotten at the present time, when there is such an outcry at the

* Of course, since the late war, Strasbourg has ceased to hold the position named.

difficulty of our "Preliminary examination," in consequence of so many of the candidates failing to acquit themselves to the satisfaction of the examiners in the elements of Grammar, Arithmetic and Latin.

THE FLUID EXTRACT OF CHESTNUT LEAVES.*

BY JOHN M. MAISCH.

In 1862,† Mr. G. C. Close called attention to the beneficial effects of the leaves of the chestnut-tree, *Castanea vesca*, L., var. *americana*, in whooping-cough. I have since learned that the leaves are popularly used and highly valued in various parts of this country as a remedy for this disease, and that in some sections of New Jersey and also of the Southern States peach leaves are employed for the same purpose. Of the latter, Dr. F. P. Porcher‡ remarks: "A tea of the leaves is a favourite domestic palliative in whooping-cough and in most pectoral affections."

The favourable effects of chestnut leaves in the disease mentioned have since been confirmed by the observations of several physicians; and from cases which have come under my notice, their use appears not only to frequently alleviate the severity of the attacks, but even to break the paroxysms, leaving merely a cough attended with mucous expectoration, which gradually yields to ordinary expectorants. Chestnut leaves, however, are not a specific against pertussis, though its effects are perhaps beneficial in a majority of cases. In 1868, during the prevalence of whooping-cough in this city, two of my children, being attacked with it, derived no benefit whatever from their use, nor had bromide of ammonium and hyoscyamus any good result; but the spasms were allayed by assafœtida, which was given in the form of syrup.

Dr. A. S. Gerhard, of Philadelphia, at whose request I have collected chestnut leaves since 1867, has used this remedy quite extensively, at first in the form of infusion, one-half to one ounce to the pint, which was freely administered; subsequently I prepared a syrup and a fluid extract, the latter preparation being greatly preferred by him on account of the small dose required, which is from a few drops to a teaspoonful, according to the age of the patient and the severity of the symptoms.

Obviously the time at which the leaves are collected must be of considerable influence upon whatever medicinal properties they may possess. I have collected them from the beginning of July, when the flowers were fully expanded, until the beginning of October; when gathered late in the fall, the green leaves only were selected. It had been my intention to use the leaves from the different months separately, with the view of having their relative efficacy tested; but the demand becoming unexpectedly large, the various collections had finally to be used indiscriminately. However, as far as the observations could be made, they appeared to be rather in favour of the fall collections made in September and early in October.

Chestnut leaves contain considerable tannin; their taste is not unpleasant, merely mildly astringent, without any decided bitterness. The remedy is therefore readily taken by children, whether in the form of sweetened infusion, syrup or fluid extract containing sugar. In preparing the fluid extract, the use of diluted alcohol as the exhausting menstruum was not attended with as satisfactory results as that of water, which was therefore employed. A purely saccharine fluid extract was of too thick a consistence, in consequence of the large amount of extractive matter dissolved by the water. After several experiments, a small quantity of glycerine was employed and the sugar correspondingly reduced, when a more attractive preparation of the consistency of a dense syrup was obtained.

One difficulty in the management of chestnut leaves in the preparation of fluid extract is their bulkiness and flexibility; dried in the air, they cannot with any degree of facility be reduced to a powder, either in the mortar or hand-mill, so that their exhaustion cannot be effected by percolation. After cutting and bruising them, they are covered with hot water in an enamelled kettle, and digested over-night, when they are expressed; the digestion and expression are repeated twice with fresh portions of water, and the three infusions, each one mixed with glycerine or a portion of the sugar, evaporated to a small bulk when they are mixed, and the evaporation continued until the proper measure is obtained; it is then set aside for several days and decanted from the small quantity of sediment.

The proportions used are as follows:—Chestnut leaves, dried, cut and bruised, 16 troy ounces; glycerine, 5 troy ounces (f℥iv); sugar, 8 troy ounces; hot water a sufficient quantity: the fluid extract to measure 16 fluid ounces.

VESICATING INSECTS.

BY M. C. COOKE, M.A.

(*Continued from page* 522.)

Potato Blister-fly, *Lytta vittata*, Oliv.; brown; elytra black, with the margin and a longitudinal band yellow.—Oliv. Ent. iii. t. 1. f. 3; Durand, Journ. Phil. Coll. Pharm. ii. p. 274. f. 4; Wood and Bache, Disp. U.S. (1867), p. 205; Warner, Amer. Journ. Pharm. xxviii. p. 195; Leidy, Amer. Journ. Med. Sc. (Jan. 1860), p. 60; Harris, Injurious Insects (1862), p. 136; Packard's Guide, p. 479. f. 452. *Lytta vittata*, Fab. Syst. p. 260; Pall. Ins. Sib. t. E. f. 33; Brandt and Ratzb. ii. t. xviii. f. 12. *Epicauta vittata*, Dej.

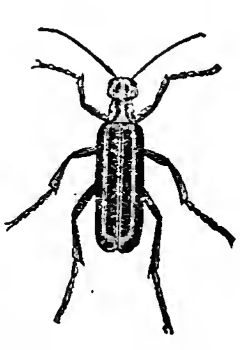

Fig. 12.—*Lytta vittata.*

Native of North America.

The potato-fly is rather smaller than *Cantharis vesicatoria*, which it resembles in shape. Its length is about six lines. The head is light red, with dark spots upon the top. The feelers are black. The elytra, or wing-cases, are black, with a longitudinal stripe in the centre and with a yellow margin. The thorax is also black, with three yellow lines, and the abdomen and legs, which have the same colour, are covered with cinereous down. It inhabits chiefly the potato plant, and appears about the end of July or beginning of August, in some seasons very abundantly. It is found on the plant in the morning and evening, but during the heat of the day it descends into the soil. The insects are collected by shaking them from the plant into hot water, and are afterwards carefully dried in the sun. They are natives of the Middle and Southern States.

This species of *Cantharis* was first described by Fabricius in the year 1871, and was introduced to the notice of the profession by Dr. Isaac Chapman, of Bucks County, Pennsylvania, who found it equal, if not superior, to the Spanish fly as a vesicatory. The testimony of Dr. Chapman has been corroborated by that of many other practitioners, some of whom have even gone so far as to assert that the potato-fly is not attended with the inconvenience of producing strangury. But this statement has been ascertained to be incorrect; and, as the vesicating property of all these insects probably depends on the same proximate principle, their operation may be considered as identical in other respects. If the potato-fly has been found more speedy in its effects than the *Cantharis* of Spain, the result is perhaps owing to the greater freshness of the former. It may be applied to the same purposes, treated in the same manner and given in the same dose as the foreign insect.

Professor Procter obtained cantharidin from this species; and Mr. W. R. Warner has shown that the proportion of this ingredient is but slightly less than in Spanish flies, the former yielding 1·99, the latter 2·03 parts in 500. Professor Leidy, of the University of Pennsylvania, ascertained by experiment that the vesicating property of this insect resides in the blood, the eggs and a peculiar fatty matter of certain accessory glands of the generative apparatus.

Occasionally potato vines are very much infested by two or three kinds of *Cantharides*, swarms of which attack and destroy the leaves during midsummer. One of these kinds has thereby obtained the name of the potato-fly. It is the *Cantharis vittata*, or striped *Cantharis*. It is of a dull tawny yellow, or light yellowish-red colour above, with two black spots on the head and two black stripes on the thorax and on each of the wing-covers. The under side of the body, the legs and the antennæ are black, and covered with a greyish down. Its length is from five to six-tenths of an inch. In this and the three following species the thorax is very much narrowed before, and the wing-covers are long and narrow, and cover the whole of the back. The striped *Cantharis* is comparatively rare in New England, but in the Middle and Western States it often appears in great numbers, and does much mischief in potato fields and gardens, eating up, not only the leaves of the potato, but those of many other vegetables. It is one of the insects to which the production of the potato-rot has been ascribed.

Brassy Blister-fly, *Lytta ænea*, Say; greenish-blue or brassy, hairy; elytra glabrous, brassy or purplish; feet rufous; knees and trochanters black. —Say's 'Entomology,' iii. p. 168. *Lymexylon æneum*, Melsheimer's 'Catalogue.' *Cantharis nigricornis*, Lec. Journ. Acad. Nat. Sc. Phil. ser. 2. i. p. 90.

Body bluish-green or dark brassy, opaque. Head punctured, hairy. Eyes oval, not emarginate, fuscous. Antennæ black, longer than the thorax, joints subturbinate, terminal one largest near the middle, acute at tip. Labrum prominent, punctured, divided by a profound sinus into two divaricated lobes. Palpi blackish. Thorax punctured, narrowed before, not wider near the middle than at base, hairy. Scutel hairy. Elytra glabrous, somewhat rugose, with two obsolete elevated lines. Feet rufous. Knees and trochanters black. Length rather more than half an inch.—Inhabits Pennsylvania.

Polished Blister-fly, *Lytta polita*, Say; head and thorax glabrous, brassy, green, polished; elytra pale olivaceous; feet rufous, trochanters and four anterior tibiæ bluish.—Say's 'Entomology,' iii. p. 169.

Body above glabrous, punctured, beneath hairy. Head brassy, polished, with distant punctures. Eyes large, oval, entire, prominent. Antennæ black, rather long. Joints oblong-conic, terminal one largest beyond the middle, abruptly narrowed so as to resemble a twelfth joint. Tip acute. Labrum blue, bilobate, lobes divaricating. Palpi black, not remarkably dilated at tip. Thorax glabrous, brassy, polished, punctured each side, distinctly wider before the middle. Scutel hairy. Elytra pale olivaceous, tinged with brassy, slightly rugose, two slightly elevated obsolete lines. Feet rufous. Knees and two anterior pairs of tibia blue. Tarsi fuscous. Length three-fifths of an inch.—Inhabits Georgia.

Brick-red Blister-fly, *Lytta afzeliana*, Fabr.; testaceous; head and thorax with black points; elytra with an oblong spot and a black sinuated line.—Fabr. Sys. El. ii. p. 78. *Cantharis sinuata*, Oliv. Ent. iii. 46. t. 2. f. 14. *Pyrota afzeliana*, Dejean.

About the size of *L. vesicatoria*. Antennæ black. Head inflexed brick-red, punctate with black. Thorax narrower than the head, brick-red, punctate with black. Elytra brick-red, with an oblong black spot at the base and a black waved line. Body varied with dingy red and black. Feet black. Base of the femora reddish.—Native of the southern states of North America.

CHEMICAL EXAMINATION OF CHAMOMILE FLOWERS.*

BY M. CAMBOULISES.

In this paper the author publishes the results of an investigation, undertaken by him, into the nature of the principles contained in the flowers of the *Anthemis nobilis*. One hundred grams of the flowers of the double-flowered variety were exhausted in a displacement apparatus by sulphuric ether, sp. gr. 0·724, and free from alcohol. The tincture so obtained, when evaporated in a water-bath, yielded 6·344 grams of ethereal extract. This was treated with boiling distilled water, which took up 0·738 gram of soluble matter, leaving an insoluble residue that weighed 5·606 grams, and consisted of a substance analogous to wax, together with a small quantity of chlorophyll. The aqueous solution of the ethereal extract, perfectly clear at first, became a

* *Journal de Pharmacie et de Chimie*, 4th ser. vol. xiv. p. 337.

little cloudy upon cooling; the turbidity increased gradually, and eventually a yellow substance was deposited, which, under the microscope, presented the appearance of small granulations. This yellow substance dissolved completely in alcohol, and gave the following reactions:—With perchloride of iron a bottle-green precipitate; with neutral acetate of lead a yellow precipitate; with ammonia a yellow precipitate. A portion of the alcoholic solution evaporated to dryness yielded a residue which, seen under the microscope, had the form of small granulations. This substance was impure quercitrin. The clear portion of the aqueous solution of the ethereal extract treated with ammoniacal sulphate of magnesia gave a brownish-yellow precipitate, composed principally of impure phosphate of ammonia and magnesia. The aqueous solution was then evaporated to dryness, and taken up by sulphuric ether. Upon spontaneous evaporation taking place, a residue was left which, under the microscope, presented the appearance of beautiful prismatic needles, possessed of great bitterness and strongly reddening litmus paper. Its solution gave no precipitate with perchloride of iron; with neutral acetate of lead, a very slight precipitate after some time; and with chloride of calcium, chloride of barium and nitrate of silver, no precipitate. Submitted to the action of heat, these crystals were decomposed without volatilization.

It appears from these facts that the flowers of *Anthemis nobilis* contain a particular acid, which is probably identical with that found by M. Pattone in the flowers of the common chamomile (*Anthemis arvensis*). The author was unable to carry his examination of this acid further, in consequence of the very small quantities obtained.

The following process may be adopted for isolating this acid:—Treat dried chamomile flowers in a displacement apparatus with ether free from alcohol, evaporate the tincture in a water-bath to the consistence of an extract; treat with boiling distilled water, filter warm, let it stand for twenty-four hours, filter afresh to separate the insoluble part, evaporate the filtrate to dryness, redissolve the residue in ether, and leave it to evaporate spontaneously.

After having exhausted the flowers with ether, the author treated them with rectified spirit. The alcoholic extract so obtained was without bitterness, and consisted principally of a yellow substance that, examined under the microscope, was seen to contain yellow globules of a rich oil.

The flowers of *Anthemis nobilis*, treated with distilled water, yielded a notable quantity of glucose. The amount of sugar indicated by analysis varied according as the estimation was made by means of Fehling's liquid, or by fermentation with beer yeast; the quantity indicated by Fehling's liquor being 23·498 per cent. of the weight of the flowers, while fermentation only indicated 14·890 per cent. It is probable, therefore, that the flowers contain, besides glucose, another substance that reduces the Fehling liquor. Professor Filhol* has previously shown that the quantity of sugar present in flowers varies from 12 to 23 per cent.

The author also analysed the inorganic matters contained in the flowers of *Anthemis nobilis*. He submitted 100 grams of the flowers to incineration in a platinum crucible, which yielded a residue weighing 6 grams. This residue, treated with distilled water, gave 2·852 grams of insoluble, and 3·175 of soluble matter.

The soluble matter was estimated as follows:—

Sulphate of potash . . .	0·8103 gram.
Chloride of potassium . .	1·1629 ,,
Carbonate of potash . . .	1·1907 ,,
Alkaline phosphate . . .	0·0111 ,,
	3·1750

The insoluble matters were estimated as follows:—

Silica	0·3967 gram.
Phosphate of lime	1·6894 ,,
Phosphate of magnesia . .	0·1593 ,,
Carbonate of lime	0·5798 ,,
	2·8252

When the author had arrived at this stage of the investigation he became acquainted with a memoir by M. Pattone, giving the results of his examination of the flowers of *Anthemis arvensis*,† and announcing the presence of an alkaloid and an organic acid in that plant. He therefore adopted the process of that operator in attempting to isolate a similar alkaloid from the flowers of *Anthemis nobilis*. Three kilograms of the dried flowers were submitted to distillation to obtain an aqueous extract. This was exhausted with boiling rectified spirit; the residue was then treated with boiling distilled water, the aqueous liquor filtered while warm, and left to cool. It deposited an abundant precipitate of phosphates, which were separated by filtration, and to the filtrate solution of ammonia was added, drop by drop, until an alkaline reaction was obtained; it was then set aside for twenty-four hours to obtain the precipitation of the alkaloid announced by M. Pattone. At the end of that time a gelatinous precipitate was formed enclosing some shining crystals, which, upon examination, were found to be crystals of phosphate of ammonia and magnesia. The gelatinous precipitate, which, according to M. Pattone, should contain the alkaloid, was treated with acetic acid; but the author failed to detect its presence by any of the usual tests for alkaloids. Treated with alcohol, the precipitate gave a solution with an alkaline reaction, and a similar result followed the use of ether. Dried and incinerated to destroy organic matter a residue was left, consisting almost entirely of phosphates of lime and magnesia.

It appears, therefore, to be satisfactorily established, that the flowers of *Anthemis nobilis* contain an organic acid exactly similar to the anthemic acid isolated by M. Pattone from the flowers of *A. arvensis*; but M. Camboulises was unable, although he followed scrupulously the process given by M. Pattone, to obtain any evidence of the presence of a corresponding alkaloid.

NOTE ON FUCUSOL.*

BY JOHN STENHOUSE, LL.D., F.R.S.

In a paper which I communicated to the Royal Society of London in 1850† "On the Oils produced by the Action of Sulphuric Acid upon various Classes of Vegetables," after describing the sources, method of preparation, and characteristic properties of furfurol, and its educts, I described another isomeric substance closely resembling furfurol, both in its physical and chemical properties, and which I named fucusol from the source whence it had been obtained, namely, *Fucus nodosus*, *F. vesiculosus* and *F. serratus*, etc.

The nature of the substance which yielded furfurol was involved in considerable obscurity until the publication of Gutzkow's paper "On the Furfurol-yielding Substance in Bran,"‡ which he found to be present in it to the amount of 15 to 20 per cent., and which, when boiled with dilute sulphuric acid, was converted into a brownish sweet syrup. This is the substance from which furfurol is obtained by distillation with sulphuric acid or hydrochloric acid.

Fucusol.

I have found that when seaweeds were boiled with very dilute sulphuric acid, containing about 3 per cent. of acid, that a substance corresponding to that described by Gutzkow was obtained, which, when distilled with sulphuric or hydrochloric acid, yielded fucusol. In my paper of the year 1850 I have described the difference in the physical properties of furfurol and fucusol, and also the difference between the products obtained by the action of ammonia upon them and the bases derived from these. I have again repeated the examination of these substances with great care, and find my former statements to be correct. In addition to these, I have recently prepared the aniline compound analogous to furfur-aniline.§ *Fucusaniline* hydrochlorate crystallizes in needles of a magnificent purple colour, and closely resembles the corresponding furfurol compound.

As is well known,|| when furfurol is boiled with water and silver oxide, metallic silver is deposited and silver pyromucate formed, which remains in solution. In a similar manner I found that when fucusol was digested at 100° C. for five or six hours with an excesss of recently precipitated silver oxide and a considerable quantity of water, its odour gradually disappeared, and at the completion of the reaction a silver-salt was found in solution, whilst metallic silver was deposited, partly in a granular state and partly as a mirror, on the bottom of the flask. Sufficient hydrochloric acid was then added to the hot filtered solution to precipitate the silver. After the removal of the argentic chloride it was carefully evaporated at a temperature below 100°; and the brown semi-crystalline mass thus obtained boiled with light petroleum oil, which dissolved the acid and left the colouring matter. One or two crystallizations from boiling water rendered it quite pure.

Analysis.—0·188 grm. substance gave 0·370 grm. carbonic anhydride and 0·080 grm. water.

		Theory.	Found.
C_5	60	53·56	53·68
H_4	4	3·57	4·25
O_3	48	42·87	—
	112	100·00	

From this analysis, it will be seen that this acid, which I propose to call β *pyromucic acid*, is isomeric with ordinary pyromucic acid, from which, however, it slightly differs in its physical properties. The melting-point of pure β pyromucic acid is 130°, being nearly the same as that of the acid obtained from furfurol, which I found to be 133°, and which Schwanert* gives as 134·3°. The β pyromucic acid from fucusol crystallizes from its aqueous solution in small rhomboidal plates, whilst the acid which I had prepared from furfurol crystallized in flat needles.

Silver β pyromucate.—This compound was prepared from the pure β acid by boiling it for a short time with silver oxide and a sufficient quantity of water, filtering, and setting aside to crystallize. A single recrystallization from boiling water, in which it is only moderately soluble, rendered it quite pure. On cooling the hot aqueous solution, the silver β pyromucate is obtained in long flat needles, whilst the corresponding salt of the ordinary acid forms small crystalline scales; 0·505 grm. of silver-salt gave 0·330 grm. argentic chloride, which corresponds to 49·18 per cent. of metallic silver. The formula $C_5H_3AgO_3$ requires 49·32 per cent.

From this silver determination it will be seen that this compound is isomeric with the ordinary silver α pyromucate, $C_5H_3AgO_3$.—*Chemical News.*

THE CONSERVATION OF FORESTS AND THE PRODUCTION OF POTASH.†

In the course of a lecture upon the importance of adopting a proper system of forest-culture in the colony of Victoria, by Baron Ferdinand von Mueller, Ph.D., F.R.S., the Government Botanist for Victoria, and Director of the Botanic Gardens of Melbourne, he thus points out the influence such a course would have upon the supply of potash, and gives some very interesting particulars concerning its production. He says:—

Among the undeveloped wood resources we must not pass that referring to potash, particularly as this alkali can be obtained without sacrifice of any valuable timber, and from localities not accessible to the wood trade.

For the preparation of potash the wood, bark, branches, and foliage are burnt in pits sunk 3 or 4 feet in the ground; the incineration is continued till the pit is almost filled with ashes. Young branches and leaves are usually much richer in potash than the stem wood, hence they should not be rejected. The ashes thus obtained are placed in tubs or casks on straw, over a false bottom. Cold water in moderate quantities is poured over the ash, and the first strong potash liquid removed for evaporation in flat iron vessels, while the weaker fluid is used for the lixiviation of fresh ashes.

While the evaporation proceeds, fresh portions of strong liquid are added until the concentrated boiling fluid assumes a rather thick consistence. At last, with mild heat and final constant stirring, the whole is evaporated to dryness. This dry mass represents crude potash, more or less impure, according to the nature of the wood employed. A final heating in rough furnaces is needed, to expel sulphur combinations, water and empyreumatic substances; also, to decompose colouring principles. Thus pearlash is obtained.

Pure carbonate of potash in crude potash varies from 40 to 80 per cent. Experiments, as far as they were instituted in my laboratory, have given the following approximate results with respect to the contents of potash in some of our most common trees. The wood of our she-oaks (*Casuarina suberosa* and *C. quadrivalvis*), as well as that of the black or silver Wattle (*Acacia decurrens*), is somewhat richer than wood of the British oak, but far richer than the ordinary pine-woods.

The stems of the Victorian blue-gum tree (*Eucalyptus globulus*), and the so-called swamp tea-tree (*Melaleuca ericifolia*), yield about as much potash as European beech. The foliage of the blue gum-tree proved particularly rich in this alkali; and as it is heavy and easily collected at

† *Gardeners' Chronicle* (1872), p. 11.

the sawmills, it might be turned there to auxiliary profitable account, and, indeed, in many other spots of the ranges.

A ton of the fresh leaves and branchlets yielded in two analyses $4\frac{3}{4}$ lb. of pure potash, equal to about double the quantity of the average kinds of pearlash. The three species of Eucalypts spontaneously occurring close around Melbourne—the red gum-tree (*Eucalyptus rostrata*), the manna gum-tree (*E. viminalis*), the box gum-tree (*E. melliodora*), produced nearly 3 lb. of pure potash, or about 5lb. of pearlash, from a ton of fresh leaves and branches; while a ton of the wood of the red gum-tree in a dried state gave nearly 2 lb. weight of pure carbonate of potash, whereas the wood of the blue gum-tree proved still richer. A ton of the dry wood of the erect she-oak (*Casuarina suberosa*) furnished the large quantity of $6\frac{1}{2}$ lb. of pure potash. This result is about equal to that obtainable from the European lime-tree or linden-tree, which again is one of the richest of all European trees in this respect.

I wish it to be distinctly understood that I do not advocate an indiscriminate sacrifice of our forest trees for any solitary one of its products, such as the potash; because by any such procedure we would still more accelerate the reduction of our woods. On the contrary, good timber, fit for splitting or for the sawmill, ought to be far too precious for potash or tar preparation. But branchwood, bark, roots, crooked stems, and even foliage, might well be utilized for this industry, wherever the place is too remote to dispose of this material for fuel. The recommendation carries with it still more weight, if we remember how on many places the close growth of suckers or seedlings has to be thinned to allow of space for the new and unimpaired upgrowth of actual timber; whereas, moreover, now the remnants at places where trees have been felled, often block by impenetrable barricades the accessible lines of traffic through the forests, and are frequently the cause of the extensive conflagrations of the woods, by placing so much combustible, dry and mostly oily material within the easy reach of the current of flames. Should, unfortunately, the fiery element have anywhere swept through the forest, it may then prove advantageous to collect the fresh ashes before they are soaked by rain, with the object of extracting from them large quantities of potash. The whole process of potash preparation being one of the simplest kind, and involving only a very trifling expense in casks and boiling-pans, can be carried out anywhere as a by-work, the profit thus being not reduced by skilled or heavy labour or by costly plant. The demand for potash must always be considerable, as it is required for the factories of nitre (particularly from soda saltpetre), one of the three principal ingredients of gunpowder and blasting-powder; it is needed also for glass, alum, various kinds of soaps, dyes and many chemicals.*

Potash, although universally distributed, is best obtained in the manner indicated. I may remark, however, though deviating from my subject, that it is one of the most potent constituents in all manures, being especially needed in the soil for all kinds of root crops, for vines and maize; nor can most other plants live without it altogether, although the quantity required may be small; but I must add that, for manuring, potash by itself would be far too valuable.

Almost every kind of forage affords potash salts, these being among the necessaries for the support of herbivorous animals. Their undue diminution in food is the cause of various diseases both in the animal and vegetable world; or predisposes, by abnormal chemic components of the organisms, to disease.

The muscles of the human structure require a comparatively large proportion of carbonate of potash; it is also absolutely required in blood, predominating in the red corpuscles. Plants grown in soil of rocks containing much felspar—such as granite, gneiss, syenite, some porphyries, diorite—are always particularly productive in potash, potassium entering largely into felspathic compounds. The latter mineral yields in most cases from 12 to 15 per cent. of potash, which, if changed to carbonate, would become augmented by nearly one-half more. It is fixed chiefly to silicic acid in felspar, and thus only tardily set free through disintegration, partly by the chemic action of air, water and various salts, partly through the mechanic force of vegetation.* The importation of potash into Victoria during 1870 was only 170 tons, but with the increase of chemical factories we shall require much more.

It has justly been argued, that the chemical analysis affords a very unsafe guide to the artisan, as regards the quantity of potash obtainable from any kind of tree or other plant, inasmuch as necessarily the percentage must fluctuate according to the nature of the soil, this again depending on geologic structure and the quality and quantity of decaying foliage on any particular spot. It should, however, not be quite forgotten, that most plants have a predilection for that soil which contains, in regions otherwise favourable to them, also due proportions of such mineral particles as are essentially necessary for the normal nutrition of the peculiar species; for, otherwise, in the wild combat for space it would succumb or give place before the more legitimate occupant of such soil. Hence, at a glance, even from long distances, we may recognize in many of our forest regions an almost abrupt line of demarcation between the gregarious trees, where one geologic formation meets or replaces the other. Thus, trees richer in potash, or oils, or any other product, may often be traced with ease over their geologic area.

* Flint-glass contains about a fifth pure pearlash; crown-glass, the best of window-glass, rather more than a quarter. Some potash-nitre is wanted also in either case.

* The proverb of chemistry—"*Corpora non agunt, nisi fluida*"—is here also applicable.

METHODS FOR PREPARING PURE CARBOLATE OF POTASH.

BY M. RAMEL.

Carbolate of potash may be prepared by mixing together alcoholic solutions containing 94 parts of carbolic acid and 56 parts of caustic potash, and evaporating. Upon cooling a crystalline mass, composed of small, very thin, transparent, micaceous plates, is deposited. Dried over sulphuric acid the product consists of carbolate of potash in a very pure salt.

This salt may also be prepared by fusing together 37·4 parts of caustic potash and 62·6 parts of carbolic acid, the caustic potash being added gradually.

In whatever way prepared, carbolate of potash absorbs humidity from the air, turning first yellow and afterwards brown. It is very soluble in water and alcohol, less so in ether. It contains no water of crystallization, but it retains the water of composition of its respective constituents, which cannot be separated without decomposition of the state.

The author states that this compound is being increasingly used in French medicine, and that as a disinfectant it advantageously replaces carbolic acid itself.—*Bull. Soc. Chim.*

THE ARTIFICIAL PRODUCTION OF DULCITE.†

BY M. G. BOUCHARDAT.

The relations which exist between the saccharine substances obtained by the action of dilute acids upon cane-sugar and the hexatomic alcohol mannite are well known. All these bodies yield similar products by oxidation and particularly saccharic acid. M. Linnemann has, within the last few years, established these relations

† Comptes Rendus, vol. lxxiii. p. 199.

in a definite manner in the production of mannite from inverted cane-sugar by hydrogenation, a result that has been verified by others:—

$$C_{12}H_{12}O_{12} + H_2 = C_{12}H_{14}O_{12},$$
$$\text{or } C_6H_{12}O_6 + H_2 = C_6H_{14}O_6.$$

Relations of the same kind appear to exist between inverted sugar of milk (galactose) and a hexatomic alcohol yielding like that body mucic acid among its products of oxidation, viz. dulcite, or an isomeride of dulcite. These relations were first indicated by M. Berthelot,* and in the present paper M. Bouchardat gives the results of some experiments verifying this fact.

An aqueous solution of inverted sugar of milk was kept in contact with 2·5 per cent. sodium amalgam for two or three days, the amalgam being added bit by bit, and the liquid neutralized from time to time by dilute sulphuric acid. The action being terminated, the solution was exactly neutralized and the greater part of the sulphate of soda removed from it, first, by crystallization, then by the addition of double its volume of concentrated alcohol. It was then filtered and evaporated to a syrupy consistence. After some time small crystalline mamelons were formed, which were removed and drained on filter paper; the liquor left to itself, deposited a fresh lot of crystals. These were easily purified by recrystallization from water.

This substance consisted of small pure crystals, gritty between the teeth, with a scarcely sweet taste, not fermenting in contact with beer-yeast. It melted at 187° C., pure dulcite fusing at 188·5° C. It was very slightly soluble in strong alcohol; water at 20° C. dissolved 4·1 per cent., while pure dulcite is dissolved in the proportion of 3·6 or 3·7 per cent., the difference arising probably from some slight impurity. The solution had no appreciable action upon polarized light, a cold saturated solution causing no deviation in a column of 200 millimetres. It did not turn brown by boiling with potash, nor did it reduce an alkaline solution of copper salt; treated with nitric acid, diluted by four times its volume of water, it yielded crystals of mucic acid. Elementary analysis gave the centesimal proportions of dulcite and mannite:—

	1st time.	2nd time.	Calculated.
C	39·10	39·3	39·5
H . . .	7·85	7·9	7·7

This body would thus appear to be identical with dulcite, $C_{12}H_{14}O_{12}$ or $C_6H_{14}O_{12}$, the natural principle first obtained from the manna of Madagascar and afterwards in the juice of *Melampyrum nemorosum.*

PHYSIOLOGICAL ACTION OF TOBACCO WHEN USED AS A NARCOTIC, WITH ESPECIAL REFERENCE TO THE CONSTITUENTS OF TOBACCO SMOKE.

BY H. VOHL AND H. EULENBERG.†

The authors first give a short account of the introduction of tobacco and a summary of its chemical history, from which they conclude that the action of tobacco, when used as a narcotic, has been erroneously attributed to the nicotine it contains. This conclusion they confirm by analyses and experiments of their own.

The amount of nicotine in snuff they found to be only from ·0392 to ·062 per cent.; in the strongest tobacco for chewing there was only a mere trace of nicotine, and in other specimens of the same kind there was none at all, so that nothing like nicotine-poisoning can result from the use of these sorts.

They then analysed the smoke of strong tobacco containing 4 per cent. of nicotine, burning part of it in a pipe and part of it as cigars. The smoke was drawn by an aspirator first through potash-solution to collect acids, and then through dilute sulphuric acid to collect bases. Besides this, the gases given off when cigars were smoked were collected and examined. These consisted of oxygen, nitrogen, carbonic oxide and marsh-gas.

The potash-solution soon became brown, acquired an almost unbearable odour of tobacco-juice, and an oily substance collected on the surface which became of a consistence like butter when cold. This oily substance was removed, washed with water and dilute sulphuric acid, and distilled. It began to boil at 200°, but the boiling-point was not constant, and gradually rose. The distillate was at first fluid and oily, but when the temperature rose to 300°, the substance which then passed over thickened on cooling to a laminated mass, which, after being several times recrystallized from ether, formed pearly-white scales, melting between 94° and 95°, and having a higher boiling-point than mercury. In these characters, as well as in their percentage composition, they agree with the carbohydrate ($C_{19}H_{18}$) discovered by Knauss, and examined by Fehling and Fritsche. The oily distillate, after repeated treatment with potash and sulphuric acid, was colourless, neutral, burned with a smoky flame, and had a specific gravity of 0·8 to 0·87. From its percentage-composition (92 and 93 C, and 8 or 7 per cent. H) it seems to be a mixture of different hydrocarbons belonging to the benzene series or a series analogous to it. None of the nitro-compounds obtained by treating it with nitric acid had any definite character, and when they were deoxidized, no trace of aniline was found, showing that benzene was absent. After separating the oily substance, the potash-solution was distilled, and the distillate added to the sulphuric acid through which the smoke had already been passed. On saturating the residue with excess of dilute sulphuric acid, keeping it well cooled, a large amount of gas was given off which consisted of carbon dioxide, hydrogen cyanide and hydrogen sulphide. The two latter gases were also detected directly in the potash-solution. When it had been used for absorption during a considerable time, the reaction of cyanogen disappeared, and that of sulphocyanogen took its place. This may be the reason of a recent statement that tobacco-smoke contains no cyanogen.

The acid potash-solution was distilled, and acetic, formic, propionic, butyric, valerianic, and carbolic acids and creasote were discovered in the distillate; caproic, caprylic and succinic acids were doubtfully present.

The sulphuric acid which had served to absorb the bases had become dark brown and thick, and a dark-brown resin had separated. The liquid was filtered, and, after addition of the distillate from the potash, partially evaporated, cooled, and saturated with caustic potash, whereupon ammoniacal vapours escaped, and a brown oil, with an odour of tobacco-juice, collected on the surface. The liquid was distilled and saturated with caustic potash redistilled, and the most volatile bases were collected in a Horsford's nitrogen-apparatus containing dilute hydrochloric acid. These were found to be ammonium chloride and traces of ethylamine. The distillate was neutralized with dilute sulphuric acid, filtered, evaporated, and treated with strong potash, the bases taken up by ether, and the ethereal solution distilled. The distillate contained only ammonia. The oily residue was dried by caustic potash and submitted to fractional distillation. The resulting bodies were further separated by repeated distillation and crystallization of their platinum-salts, and at last the whole series of picoline or pyridine bases, analogous to the aniline bases, were obtained.

The identity of the following bases was determined by the boiling-point, percentage-composition, and the composition of the platinum double salt:—Pyridine, C_5H_5N, boiling-point 115°–116°. Picoline, C_6H_7N, boiling-point 134°–135° C. Lutidine, C_7H_9N, boiling-

† Arch. Pharm. [2] cxlvii. 130–166, from the *Journal of the Chemical Society.*

point 155°. Collidine, $C_8H_{11}N$, boiling-point 171·5°, is isomeric with xylidine, and is identified by the authors with the aldehydin of Ador and Baeyer by its composition and characters. Parvoline, $C_9H_{13}N$, boiling-point 187°–188°, isomeric with cumidine. Coridine, $C_{10}H_{15}N$, boiling-point 211°. Rubidine, $C_{11}H_{17}N$, boiling-point 230°, and, probably, Viridine, $C_{12}H_{19}N$, boiling-point 251°, were obtained in too small quantities to determine their percentage-composition, and were identified by their boiling-points and platinum salts. Nicotine was carefully looked for, but no trace of it was found, and the authors thus fully confirm the observations made by Zeise in 1843, that it does not exist in tobacco-smoke. They find that it can be easily separated from the pyridine bases, as it forms with zinc chloride a double salt difficultly soluble in alcohol, which the pyridine bases do not. The formula of this salt is $C_{10}H_{14}N\,2\,HCl\,Zn\,Cl_2 + 8\,H_2O$. The fact that stronger tobacco can be smoked in cigars than in a pipe is explained by the greater proportion of volatile bases present in the smoke of a pipe, and especially by the large quantity of very volatile and stupefying pyridine, while in a cigar little pyridine and much collidine is formed.

The authors think that the disagreeable symptoms which are felt by persons beginning to smoke, and the chronic affections which occur in those who smoke to excess, as well as the cases of poisoning from swallowing tobacco-juice, are due, not to nicotine, but to the pyridine and picoline bases. The idea that they were due to nicotine originated in the fact that picoline bases having a high boiling-point, such as parvoline, resemble that alkaloid greatly both in smell and in physiological action.

The authors did not test the physiological action of each base separately, but only that of a mixture of those bases which volatilize under 160°, and of those between 160° and 250°.

Both of these produced, like nicotine, contraction of the pupil, difficulty of breathing, general convulsions, and death. On *post-mortem* examination the respiratory passages and lungs were found congested. They act more quickly when taken internally than when injected subcutaneously, but they do not act so quickly as nicotine.

Plants which contain no narcotic are not unfrequently used for smoking, instead of tobacco. The authors tested the action of the pyridine bases produced from dandelion, willow-wood, stramonium, and of pure picoline from boghead coal. These had an action very much resembling, though weaker than, that of the bases from tobacco; but with the exception of those from willow-wood, they produced no contraction of the pupil. The vapour of picoline was also tested and found to be poisonous, producing great irritation of the respiratory passages, slight convulsions, and death.

The authors are acquainted with a person who can swallow the juice from a tobacco-pipe without being affected by it, but they consider that this exception does not impair the rule that picoline bases have a powerful action on the organism. They also think that the action of opium, when smoked, is not due to the alkaloids it naturally contains, and that the difference of its action from that of tobacco is simply due to a difference in the bases which are produced when the two substances are smoked.

CHROMIC ACID AS AN ANTISEPTIC, DISINFECTANT, ETC.,

More Especially as Compared with Carbolic Acid.*

BY JOHN DOUGALL, M.D. GLAS.

(*Continued from page 546.*)

Power in preventing animalcules.—As a preventive of germ life, chromic acid surpasses sixty-six other chemical bodies consisting of irritant, narcotic, and narcotico-irritant poisons, including all the known antiseptics and disinfectants, except two or three substances, with which it has not yet been compared. In this respect it greatly excels carbolic acid, the average preventive strength of which, in three aqueous solutions of hay, urine, beef-juice, and egg albumen, is only 1 to 400, while that of chromic acid is 1 to 3300.*

Effects on animals.—The results of various experiments on rabbits, etc. show that chromic acid, in concentrated solutions, is a pure and powerful corrosive of animal textures, effecting speedy and complete local disorganization. So actively does it destroy the vascular tunics, gelatinizing their fluid contents, that absorption is rendered impossible; these, by the merest contact with the acid, being converted into consolidated emboli, which choke the capillary passages and preclude further ingress. This view is confirmed by, or may be inferred from, the fact of the poison not being found in the blood or urine. If equal portions of muscular tissue and chromic acid be left in contact for about one hour, the whole is converted into a mass like burnt sugar, which is freely soluble in water, rendering it yellowish-brown.

Chrome sores.—Through the kindness of Messrs. White, of Shawfield, near Rutherglen, the largest makers of bichromate of potassium in this country, I had an opportunity lately of examining some of the "chrome sores" on the bodies of several workmen. These occur chiefly on the hands and exposed parts, and are said to arise from the salt coming in contact with a denuded cuticular surface. The first symptom is pain, succeeded by redness; and latterly the affected part assumes a papular or furunculoid form. After the lapse of some days, a cylindrical slough or core exudes from the centre of the swelling, leaving a deep pit with nearly vertical walls, the bottom of which generally extends through the cutis vera, and not unfrequently into or through some of the muscles. The sores are long of healing, doubtless from loss of structure, the salt acting like its acid, though with less intensity.

Chromic acid in this form has been said to have a strong propensity for the destruction of cartilage, inasmuch as the nasal alæ and septum, and even the larynx, of workmen employed in the manufacture of bichrome are frequently greatly corroded by it. The ulceration has been considered similar to that of tertiary syphilis, and bichloride of mercury recommended as an antidote, and, withal, this absurdity has been promulgated by a standard work on chemistry.† From experiments made with the acid on portions of the trachea of a cow, the reverse is proved to be the case. Indeed, chromic acid might rather be said to have a specific action on gelatine or muscle, because breaches of surface are here the rule, whereas ulceration of cartilage is the exception. The cause of the nasal and laryngeal affection is clearly the same as that of the other sores—a cuticular hiatus; and while there seems an additional reason why the nasal walls should be attacked more than other parts, still that is fully counterbalanced by the material of which they are composed resisting the action of the acid more; hence it is seldomer affected.

During respiration in an atmosphere contaminated with floating particles of the chromic salt, these are constantly brought in contact with the anterior nares, etc.; and, dissolving in the nasal secretion, set up irritation, which, if prolonged, results in abrasion of the mucous membrane. What follows is plain: each inspiration deposits a variable quantity of the salt upon the affected part, resulting in ulceration.

As a test for strychnia.—Chromic acid elicits the coloured reaction in a solution containing $\frac{1}{100000}$ of strychnia. The *modus operandi* is to put two or three

* Reprinted from the *Lancet*, vol. ii. (1871) p. 912.

* 'On the Relative Powers of Various Substances in Preventing Animalcules." Churchills.

† In Meadows's 'Prescribers' Companion' (page 152) potassæ bichromas is said to have been recommended as an antisyphilitic.

minims of the strychnia fluid on a white non-porous surface, then and a few needles of chromic acid, which instantly dissolve, imparting to the liquid their characteristic tint. One or two drops of *concentrated sulphuric acid* are now added, and the play of colour is at once evolved. With stronger solutions the result is very distinct, and in any case unfailing. In applying this test the above method must be strictly adhered to; because if sulphuric acid be added to the strychnia solution before the chromic acid, the latter will not dissolve, and the result is negative. Chromic acid does not give the coloured reaction with dilute sulphuric acid.

It is well known that bichromate of potassium, so commonly used for this test, does not always succeed. I have seen it fail in the hands of two professors—one a celebrated toxicologist—when attempting to show it to their class, and am not aware that any explanation of the cause of this frequent miscarriage has been given, though it seems to me as follows:—It is obvious from the fact of chromic acid giving the coloured test at all that to it alone the reaction is due when bichrome is used; that neither the potash in the latter, nor the sulphate of potash resulting from the addition of sulphuric acid, are indispensable agents in developing the reaction. Furthermore, as strong sulphuric acid is necessary both when using bichrome and chromic acid *per se*, it is evident that, when added to the first, the result is the formation of sulphate of potassium, water, and free chromic acid: indeed, this is exactly the method by which the latter is prepared, as shown in the following equation:—

$$K_2O\ 2\ CrO_3 + H_2SO_4 = K_2SO_4 + H_2O\ 2\ CrO_3.$$
